Expansion in $SL_d(O_K/I)$, $I$ square-free

Péter P. Varjú
January 20, 2010

Abstract

Let $S$ be a fixed symmetric finite subset of $SL_d(O_K)$ that generates a Zariski dense subgroup of $SL_d(O_K)$ when we consider it as an algebraic group over $\mathbb{Q}$ by restriction of scalars. We prove that the Cayley graphs of $SL_d(O_K/I)$ with respect to the projections of $S$ is an expander family if $I$ ranges over square-free ideals of $O_K$ if $d = 2$ and $K$ is an arbitrary numberfield, or if $d = 3$ and $K = \mathbb{Q}$.

1 Introduction

Let $G$ be a graph, and for a set of vertices $X \subset V(G)$, denote by $\partial X$ the set of edges that connect a vertex in $X$ to one in $V(G) \setminus X$. Define

$$c(G) = \min_{X \subset V(G), |X| \leq |V(G)|/2} \frac{|\partial X|}{|X|},$$

where $|X|$ denotes the cardinality of the set $X$. A family of graphs is called a family of expanders, if $c(G)$ is bounded away from zero for graphs $G$ that belong to the family. Expanders have a wide range of applications in computer science (see e.g. Hoory, Linial and Widgerson [21] for a recent survey of expanders and their applications) and recently they found remarkable applications in pure mathematics as well (see Bourgain, Gamburd and Sarnak [8] and Long, Lubotzky and Reid [23]).

Let $G$ be a group and let $S \subset G$ be a symmetric (i.e. closed for taking inverses) set of generators. The Cayley graph $\mathcal{G}(G,S)$ of $G$ with respect to the generating set $S$ is defined to be the graph whose vertex set is $G$, and in which two vertices $x, y \in G$ are connected exactly if $y \in Sx$. Let $K$ be a number-field and denote by $O_K$ its ring of integers. Let $I \subset O_K$ be an ideal, and denote by $\pi_I$ the projection $O_K \to O_K/I$. In this paper we study the problem whether the graphs $\mathcal{G}(SL_d(O_K/I), \pi_I(S))$ form an expander family, where $S \subset SL_d(O_K)$ is a fixed symmetric set of matrices and $I$ runs through certain ideals of $O_K$. This problem was addressed by Bourgain and Gamburd in a series of papers [5]–[7], and by them jointly with Sarnak in [8]. It is solved for $K = \mathbb{Q}$ in the following cases: in [5] for $d = 2$, when and $I = (p)$ runs through primes, in [8] for $d = 2$ and $I = (q)$, $q$ is square-free and in [6] and [7] when $I = (p^n)$, $p^n$ is a primepower.
Note that by the above remarks on Helfgott’s work, the theorem is unconditional
otherwise the theorem. We remark that the condition on Zariski density is necessary,

(When \( d \geq 3 \), the prime \( p \) has to be kept fixed.) The necessary and sufficient
condition in each case for the Cayley graphs to be expanders is that \( S \) generates
a Zariski dense subgroup \( \Gamma < SL_d(\mathbb{C}) \). In [8] the expander property is used for
\( K = \mathbb{Q}(\sqrt{-1}) \) for sieving in the context of integral Apollonian packings, this is
our main motivation for extending the problem for general number-fields.

The starting point for our study is the work of Helfgott [18], [19]. He studies
the following problem: Let \( \mathcal{F} \) be a family of finite fields and let \( d \geq 2 \) be an
integer. Is there a constant \( \delta > 0 \) such that for any generating set \( A \subset SL_d(F) \),
\( F \in \mathcal{F} \) we have

\[
|A.A.A| \geq |A| \min(|A|,|SL_d(F)|/|A|)^\delta \tag{1}
\]

Here and everywhere in what follows, we use the notation

\[
A.B = \{gh \mid g \in A, h \in B\},
\]

if \( A \) and \( B \) are subsets of a multiplicative group. Helfgott answers this question
to the affirmative, when \( \mathcal{F} \) is the family of prime fields and \( d = 2 \) [18] or \( d = 3 \)
[19]. In section 4.1 we show that [18] (i.e. the proof for the case \( d = 2 \)) easily
extends to the case of arbitrary finite fields.

Let \( r \) be the degree of the number-field \( K \), and denote by \( \sigma_1, \ldots, \sigma_r \) the
embeddings of \( K \) into \( \mathbb{C} \). Denote by \( \tilde{\sigma} = \sigma_1 \oplus \cdots \oplus \sigma_r \) the obvious map \( K \to \mathbb{C}^r \).
This gives rise to an embedding (which will also be denoted by \( \tilde{\sigma} \)) of \( SL_d(\mathcal{O}_K) \)
into the direct product \( SL_d(\mathbb{C})^r \). Our main result is

**Theorem 1.** Let \( S \subset SL_d(\mathcal{O}_K) \) be symmetric and assume that it generates a
subgroup \( \Gamma < SL_d(\mathcal{O}_K) \) such that \( \tilde{\sigma}(\Gamma) \subset SL_d(\mathbb{C})^r \) is Zariski dense. Assume
further that (1) holds for some constant \( \delta > 0 \) if \( F \) ranges over the fields \( \mathcal{O}_K/P \),
where \( P \subset \mathcal{O}_K \) is a prime ideal. Then there is an ideal \( J \subset \mathcal{O}_K \) such that
\( \mathcal{G}(SL_d(\mathcal{O}_K/I),\pi_I(S)) \) is a family of expanders if \( I \subset \mathcal{O}_K \) ranges over square-
free ideals prime to \( J \).

It is contained in the claim that \( \pi_I(S) \) generates \( SL_d(\mathcal{O}_K/I) \) if \( I \) is prime
to \( J \). In fact, \( J \) can be taken to be the product of prime ideals \( P \) for which
\( \pi_P(S) \) does not generate \( SL_d(\mathcal{O}_K/P) \), this fact will be proven together with the
theorem. We remark that the condition on Zariski density is necessary, otherwise \( \pi_{(q)}(S) \) would not generate \( SL_d(\mathcal{O}_K/(q)) \) for any rational integer \( q \).

We introduce some notation that will be used throughout the paper. We use
Vinogradov’s notation \( x \ll y \) as a shorthand for \( |x| < Cy \) with some constant
\( C \). Let \( G \) be a discrete group. The unit element of any multiplicatively written
group is denoted by \( 1 \). For given subsets \( A \) and \( B \), we denote their product-set by

\[
A.B = \{gh \mid g \in A, h \in B\},
\]

while the \( k \)-fold iterated product-set of \( A \) is denoted by \( \prod_k A \). We write \( \hat{A} \) for
the set of inverses of all elements of \( A \). We say that \( A \) is symmetric if \( A = \hat{A} \).
The number of elements of a set \( A \) is denoted by \( |A| \). The index of a subgroup
$H$ of $G$ is denoted by $[G : H]$ and we write $H_1 \lesssim_L H_2$ if $[H_1 : H_1 \cap H_2] \leq L$ for some subgroups $H_1, H_2 < G$. Occasionally (especially when a ring structure is present) we write groups additively, then we write

$$A + B = \{g + h \mid g \in A, h \in B\}$$

for the sum-set of $A$ and $B$, $\sum_k A$ for the $k$-fold iterated sum-set of $A$ and 0 for the unit element.

If $\mu$ and $\nu$ are complex valued functions on $G$, we define their convolution by

$$(\mu \ast \nu)(g) = \sum_{h \in G} \mu(gh^{-1})\nu(h),$$

and we define $\tilde{\mu}$ by the formula

$$\tilde{\mu}(g) = \mu(g^{-1}).$$

We write $\mu^{(k)}$ for the $k$-fold convolution of $\mu$ with itself. As measures and functions are essentially the same on discrete sets, we use these notions interchangeably, we will also use the notation

$$\mu(A) = \sum_{g \in A} \mu(g).$$

A probability measure is a nonnegative measure with total mass 1. Finally, the normalized counting measure on a finite set $A$ is the probability measure

$$\chi_A(B) = \frac{|A \cap B|}{|A|}.$$

We use the same approach to prove Theorem 1 as in [5]–[8] which goes back to [28], we outline this here only, the details will be given in section 5. Let $G$ be an $m$-regular graph, i.e. each vertex is of degree $m$. It is easy to see that the largest eigenvalue of the adjacency matrix of $G$ is $m$, and it is a simple eigenvalue if and only if the graph is connected. Denote by $\lambda_2(G)$ the second largest eigenvalue of the adjacency matrix. It was proven by Dodziuk [13], Alon and Milman [3] and Alon [2] that a family of graphs is an expander family, if and only if $m - \lambda_2(G)$ is bounded away from zero, see also [21, Theorem 2.4]. For a Cayley graph $G(G, S)$, the adjacency matrix is a constant multiple of convolution by $\chi_S$ from the left considered as an operator. Then the multiplicities of the nontrivial eigenvalues are at least the minimum dimension of a nontrivial representation of $G$. In the case of $SL_d$ good bounds are know, hence it is enough to estimate the trace of the operator. More precisely, with the notation of Theorem 1, we need to show that for any $\varepsilon > 0$ there is a constant $C = C(\varepsilon, S)$ such that

$$\|\pi_I(\chi_S^{(C \log N(I))})\|_2 < |SL_d(\mathcal{O}_K/I)|^{-1/2+\varepsilon},$$

where $N(I)$ is the norm of the ideal. In fact, (2) means that the random walk on $G(SL_d(\mathcal{O}_K/I), \pi_I(S))$ is close to equidistribution after $C \log N(I)$ steps.

The proof of (2) has two parts, the first is
Theorem 2. Let \( S \subset SL_d(O_K) \) be symmetric, and denote by \( \Gamma \) the subgroup it generates. Assume that \( \hat{\sigma}(\Gamma) \) is Zariski dense in \( SL_d(C)^r \). Then there is a constant \( \delta \) depending only on \( S \), and there is a symmetric set \( S' \subset \Gamma \) such that the following holds. For any square-free ideal \( I \), for any proper subgroup \( H < SL_d(O_K/I) \) and for any even integer \( l \geq \log N(I) \), we have
\[
\pi_I[\chi_S^{(l)}](H) \ll [SL_d(O_K/I) : H]^{-\delta}.
\]

If we know that \( g \in \prod_{c \log N(I)} S \), where \( c \) is a small constant depending on \( S \), then \( \pi_I(g) \) determines \( g \) uniquely. In section 2, using Nori’s [25] results we give a geometric description of the elements of \( \prod_{c \log N(I)} S \) whose projection modulo \( I \) belong to \( H \), this will be a certain subgroup of \( SL_d(O_K) \). Then we will prove that the probability for the random walk on \( G(\Gamma, S) \) to be in this subgroup decays exponentially in the number of steps we take. (Actually, first we need to replace \( S \) by another set \( S' \subset \Gamma \).) The proof of this is based on a ping-pong argument.

The second part of the proof begins with the following observation. If we apply Theorem 2 for \( H = \{1\} \), then we already get
\[
\|\pi_I[\chi_S^{(\log N(I))}]\| \ll [SL_d(O_K/I)]^{-\delta/2}.
\] (3)

Now working on the quotient \( SL_d(O_K/I) \), we can improve on (3), if we take the convolution of \( \pi_I[\chi_S^{(\log N(I))}] \) with itself. More precisely we prove in section 3 the following

Theorem 3. Let \( G \) be a group satisfying the assumptions (A0)–(A5) listed in section 3. Then for any \( \varepsilon > 0 \), there is some \( \delta > 0 \) depending only on \( \varepsilon \) and the constants appearing in assumptions (A0)–(A5) such that the following holds. If \( \mu \) and \( \nu \) are probability measures on \( G \) such that
\[
\|\mu\|_2 > |G|^{-1/2+\varepsilon} \quad \text{and} \quad \mu(gH) < [G : H]^{-\varepsilon}
\]
for any \( g \in G \) and for any proper subgroup \( H < G \), then
\[
\|\mu * \nu\|_2 < \|\mu\|_2^{1/2+\delta} \|\nu\|_2^{1/2}.
\]

Assumptions (A0)–(A5) are too technical so we do not list them here in the introduction. Among other things, we assume that \( G \) is the direct product of such quasi-simple groups that also satisfy the conclusion of the theorem. To prove the latter for the groups \( SL_d(O_K/P) \) we need (1), and this is the reason why we have Theorem 1 only in the cases, when (1) is available. The quasi-simplicity of the factors is a severe restriction, for example it excludes factors of the form \( SL_d(O_K/P^k) \), where \( P \) is a prime ideal. Therefore a new idea is needed to prove Theorem 1 for general ideals.

A similar result for \( G = SL_2(Z/qZ) \), \( q \) square-free (under stronger hypothesis on \( \mu \)) is given by Bourgain, Gamburd and Sarnak [8, Proposition 4.3]. They use an argument similar to Helfgott’s [18] to reduce it to a so-called sum-product
Theorem for the ring \( \mathbb{Z}/q\mathbb{Z} \). Then they prove the latter by reducing it to the case of \( \mathbb{Z}/p\mathbb{Z} \), \( p \) prime. The difference in our approach is that we use Helfgott’s theorem as a black box, and extend it to the case of square-free modulus in a way that very much resembles the proof given in [8, section 5] for the sum-product theorem.

Acknowledgement. I am very grateful to my advisor, Jean Bourgain for suggesting this problem and for guiding me during my research. I also had very useful discussions with Elon Lindenstrauss, Alireza Salehi Golsefidy and Peter Sarnak, I thank them for their interest and for their valuable remarks.

While writing this paper, I was supported by a Fulbright Science and Technology Award, grant no. 15073240.

2 Escape of mass from subgroups

We prove Theorem 2 in this section. First we note that we may assume that \( I \) is a principal ideal generated by a square-free rational integer \( q \). Indeed, there is always a square-free rational integer \( q \in I \) such that \( q \leq N(I) \). Let \( \tilde{H} \) be the preimage of \( H \) under the projection \( SL_d(\mathcal{O}_K/(q)) \to SL_d(\mathcal{O}_K/I) \). Then we have \( \log N((q)) \geq \log N(I) \geq \log N((q))/r \) and \( [SL_d(\mathcal{O}_K/I) : H] = [SL_d(\mathcal{O}_K/(q)) : \tilde{H}] \). Hence the claim of the theorem for \( I \) and \( H \) follows from the claim for \( (q) \) and \( \tilde{H} \). In what follows we assume that \( I = (q) \) and write \( \pi_q = \pi_{(q)} \).

Let \( q = p_1 \ldots p_n \) be the prime factorization of \( q \) and assume without loss of generality that none of the \( p_i \) ramify in \( K \).

For \( g \in SL_d(\mathbb{C}) \) denote by \( \|g\| \) the operator norm of \( g \) with respect to the \( l^2 \) norm on \( \mathbb{C}^d \). If \( \|g\| < \sqrt{q}/2 \) for some \( g \in SL_d(\mathcal{O}_K) \), then clearly \( \|g'\| > \sqrt{q}/2 \) for any other \( g' \in SL_d(\mathcal{O}_K) \) with \( \pi_q(g) = \pi_q(g') \) since \( \|g\| \geq \sqrt{q} \) if \( \pi_q(g) = 0 \) and \( g \neq 0 \). Hence elements of small norm are determined uniquely by their projections modulo \( q \). The first step towards the proof of Theorem 2 is to study when the projection of an element of small norm belong to \( H \), i.e. we study the set

\[
\mathcal{L}_\delta(H) := \{ h \in SL_d(\mathcal{O}_K) \mid \pi_q(h) \in H, \|\tilde{\sigma}(h)\| < [SL_d(\mathcal{O}_K/(q)) : H]^\delta \}
\]

for \( \delta > 0 \) and for \( H < SL_d(\mathcal{O}_K/(q)) \).

By Weil restriction of scalars, we consider \( SL_d(K) \) as the \( \mathbb{Q} \)-points of an algebraic group. To fix notation, we describe this process in detail. Let \( e_1, \ldots, e_r \) be an integral basis of \( \mathcal{O}_K \). Multiplication by an element \( a \in K \) is an endomorphism of the \( \mathbb{Q} \)-vector space \( K \). This gives rise to an embedding \( \alpha : K \to Mat_r(\mathbb{Q}) \) onto a subalgebra of \( Mat_r(\mathbb{Q}) \) which is defined by linear equations over \( \mathbb{Q} \). Thus there is an algebraic subgroup \( G \) of \( SL_{dr} \) defined over \( \mathbb{Q} \) such that \( SL_d(K) \) is isomorphic to \( G(\mathbb{Q}) \) as an abstract group, we denote this isomorphism by \( \alpha \) as well. Moreover, we have \( \alpha(SL_d(\mathcal{O}_K)) = G(\mathbb{Q}) \cap SL_{dr}(\mathbb{Z}) \). To shorten notation, we write \( G(\mathbb{Z}) = G(\mathbb{Q}) \cap SL_{dr}(\mathbb{Z}) \). The image of \( e_1, \ldots, e_r \) under \( \pi_q \) is a basis of the \( \mathbb{Z}/q\mathbb{Z} \)-module \( \mathcal{O}_K/(q) \), hence
Lemma 5. \(\alpha\) induces an isomorphism from \(SL_d(O_K/(q))\) to \(G(Z/qZ)\). Denote by \(g\) the Lie-algebra of \(G\), then \(g(Q)\) is a subspace of \(Mat_{d^r}(Q)\) defined by (linear) polynomials \(\varphi_1, \ldots, \varphi_{d^r-1} \in \mathbb{Z}[x]\). If \(p\) is a prime which does not ramify in \(K\), then we can write \((p) = P_1 \cdots P_k\) with different prime ideals \(P_i\). Then \(G(Z/pZ)\) is isomorphic to \(SL_d(O_K/P_1) \times \cdots \times SL_d(O_K/P_k)\).

Proposition 4. There are constants \(C\) and \(\delta\) depending only on \(K\) such that the following holds. For any subgroup \(H < SL_d(O_K/(q))\), there are \(u, v \in g(C)\) and there is a subgroup \(H^2 < H\) with \([H : H^2] < C^n\), such that if \(h \in L_d(H^2)\) then
\[
\text{Tr}(\alpha(h)u\alpha(h)^{-1}v) = 0,
\]
but there is some \(g_0 \in G(Q)\) such that \(\text{Tr}(g_0ug_0^{-1}v) = 1\).

In what follows we often write \(F_{p^m}\) for the finite field of order \(p^m\). Recall that \(n\) is the number of prime factors of \(q\) and \(q = p_1 \cdots p_n\). Then \(G(Z/qZ) = G(F_{p_1}) \times \cdots \times G(F_{p_n})\). For \(q_1 | q\), denote by
\[
\pi_{q_1} : G(Z/qZ) \to \times_{p|q_1} G(F_p)
\]
the projection to the product of direct factors corresponding to the prime factors of \(q_1\). Fix a proper subgroup \(H < G(Z/qZ)\) and denote by \(q_1\) the product of all primes \(p|q\) for which \(\pi_p(H) = G(F_p)\). In the course of the proof we will replace \(q\) by \(q/q_1\) and \(H\) by \(\pi_{q/q_1}(H)\). We need to show that \([G(Z/(q/q_1)Z) : \pi_{q/q_1}(H)]\) is not much smaller than \([G(Z/qZ) : H]\). For this we first give

Lemma 5. Let \(p_1\) and \(p_2\) be two different primes and assume that \(N < H < SL_d(F_{p^m_2})\) such that \(H/N\) is isomorphic to \(PSL_d(F_{p^m_1})\) with some integers \(m_1, m_2\). Then
\[
p_1 \mid p_2m_1 \prod_{i=2}^d (p_2^{m_1} - 1),
\]
in particular, for a fixed \(p_2\) the product of all primes, which can arise as \(p_1\), is at most \(p_2^{m_1}\).

Proof. As \(PSL_d(F_{p^m_1})\) has an element of order \(p_1\) and the order of \(SL_d(F_{p^m_2})\) is \(p_2^{m_1d(d-1)/2} \prod_{i=2}^d (p_2^{m_1} - 1)\), the assertion is clear.

Lemma 6. Let \(H\) be a subgroup of \(G = G(Z/qZ)\) and denote by \(q_1\) the product of primes \(p|q\) with \(\pi_p(H) = G(F_p)\) and set \(q_2 = q/q_1\). There is a subgroup \(H_2 < G(Z/q_2Z)\) of the form \(\times_{p|q_2} H_p\), where each \(H_p\) is a proper subgroup of \(G(F_p)\) such that \(\pi_{q_2}(H) < H_2\) and
\[
[G(Z/q_2Z) : H_2] > [G : H]^c
\]
with a constant \(c\) depending only on \(d\) and \(r\).
Proof. If for some $p|q_1$, $G(F_p)$ is a direct factor of $H$ then

$$[G(Z/(q/p)Z) : \pi_{q/p}(H)] = [G : H],$$

hence we can assume without loss of generality that there is no such prime. We show that for each $p_1|q_1$, there is some $p_2|q_2$ such that the conditions of the previous lemma are satisfied. This will yield a bound on $q_1$. Set $q' = q/p_1$. By Goursat’s Lemma, there is a nontrivial group $N$ and surjective homomorphisms

$$\varphi : \pi_p(H) = G(F_{p_1}) \to N, \quad \psi : \pi_{q'}(H) \to N.$$  

For each factor $p|q'$, $\psi$ gives rise to a surjective homomorphism

$$\psi_p : \pi_p(H) \to N_p = N/\{\psi(h) \mid h \in \pi_{q'}(H), \pi_p(h) = 1\}$$  

in the obvious way. Since the intersection of all the subgroups $\{\psi(h) \mid h \in \pi_{q'}(H), \pi_p(h) = 1\}$ is trivial, there is a prime $p_2$ for which $N_{p_2}$ is nontrivial. As $G(F_{p_1})$ and $G(F_{p_2})$ have no nontrivial common factors, $p_2|q_2$. It is clear that $p_1$ and $p_2$ satisfy the conditions of Lemma 5, whence $q_1 < q_2^{d^2}$.

For each $p|q_2$ let $H_p$ be a proper subgroup of $G(F_p)$ containing $\pi_p(H)$. Since $G(F_p)$ is generated by its subgroups isomorphic to $SL_2(F_p)$, there must be at least one such subgroup which is not contained in $H_p$. Any proper subgroup of $SL_2(F_p)$ is of index at least $p + 1$, hence $[G(F_p) : H_p] > p$. This shows that for $H_2 = \times_{p|q_2} H_p$, we have

$$[G(Z/q_2Z) : H_2] > q_2 > q^{1/(d^2r+1)} > [G : H]^c.$$

The proof of Proposition 4 is based on the description of subgroups of $GL_d(F_p)$ given by Nori [25] that we recall now. Let $H$ be a subgroup of $GL_d(F_p)$ and denote by $H^+$ the subgroup of $H$ generated by its elements of order $p$. [25, Theorem B] states that if $p$ is bigger than a constant depending only on $d$, then there is a connected algebraic subgroup $\bar{H}$ of $GL_d$ defined over $F_p$ such that $H^+ = \bar{H}(F_p)^+$. Denote by $\mathfrak{h}$ the Lie algebra of $\bar{H}$, and define exp and log by

$$\exp(z) = \sum_{i=0}^{p-1} \frac{z^i}{i!} \quad \text{and} \quad \log(z) = -\sum_{i=1}^{p-1} \frac{(1 - z)^i}{i}$$  

for $z \in Mat_d(F_p)$. Then for $p$ large enough, exp and log sets up a one to one correspondence between elements of order $p$ of $H^+$ and nilpotent elements $\mathfrak{h}(F_p)$ by [25, Theorem A]. Moreover $\mathfrak{h}(F_p)$ is spanned by its nilpotent elements. To understand subgroups not generated by the elements of order $p$, we will use [25, Theorem C] which asserts that if $p \geq d$, then there is a commutative subgroup $F < H$ such that $FH^+$ is a normal subgroup of $H$ and its index $[H : FH^+]$ is bounded in terms of $d$. 

7
Proof of Proposition 4. We follow the argument in [7, Proposition 4.1]. Recall that $H$ is a subgroup of $SL_d(O_K/(q))$. Apply Lemma 6 to $\alpha(H)$ to get a modulus $q_2|q$ and a subgroup $H_2 < G(Z/qZ)$. Suppose that the proposition holds for $\alpha^{-1}(H_2)$ and for an $H_2^2 < SL_d(O_K/(q_2))$ with $[H_2 : \alpha(H_2^2)] < C^n$. Set

$$H^2 = \{h \in H \mid \pi_{q_2}(h) \in H_2^2\},$$

and observe that $[H : H^2] < C^n$ and $L_\delta(H^2) \subset L_{\delta/c}(H_2^2)$ with the constant $c$ from Lemma 6. Therefore, if the proposition holds for $\alpha^{-1}(H_2)$ and $H_2^2$, it also holds for $H$ and $H^2$. We assume in what follows that $\alpha(H) = H_{p_1} \times \ldots \times H_{p_n}$, where $q = p_1 \cdots p_n$ is the prime factorization of $q$ and $H_{p_i}$ is a proper subgroup of $G(F_{p_i})$. For each direct factor $H_{p_i}$, let $H_{i}^2 < H_{p_i}$ be such that $H_{i}^2/H_{p_i}^+$ is commutative and $[H_{p_i} : H_{i}^2] < C$ with a constant $C$ depending on $r$ and $d$, such a subgroup exists by [25, Theorem C]. Define $H^2 = \alpha^{-1}(H_{p_1}^2 \times \ldots \times H_{p_n}^2)$. For each $g \in G(Z)$ define the polynomial $\eta_g \in Z[X,Y]$ with $X = (X_{l,k})_{1 \leq l, k \leq dr}$ and $Y = (Y_{l,k})_{1 \leq l, k \leq dr}$ by

$$\eta_g(X,Y) = \text{Tr}(gXg^{-1}Y).$$

Let $A$ be a fixed set of generators of $G(Z)$ and fix an element $g_0 \in A$. Consider the system of equations

$$\begin{align*}
\varphi_i(X) &= 0 & 1 \leq i \leq r^2d^2 - r(d^2 - 1), \\
\varphi_i(Y) &= 0 & 1 \leq i \leq r^2d^2 - r(d^2 - 1), \\
\eta_{\alpha(h)}(X,Y) &= 0 & h \in L_\delta(H^2), \\
\eta_{g_0}(X,Y) &= 1,
\end{align*}$$

(4)

where $\delta$ is a small constant depending on $d$ and $r$ to be chosen later. Recall that $\varphi_i$ are the polynomials defining the Lie algebra $g$. The assertion follows once we show that (4) has a solution $X = u, Y = v \in Mat_{rd}(C)$ for an appropriate choice of $g_0$.

First we show that for each $p = p_i$, there is at least one $g_0 \in A$ such that (4) has a solution in $Mat_{rd}(F_p)$. We apply the results of [25] for $H = H_p$, in particular let $\bar{H}$ and $h$ be the same as in the discussion preceding the proof. Conjugation by an element $g \in G(F_p)$ permutes elements of order $p$ of $H^+_p$ if and only if it permutes nilpotent elements of $h(F_p)$. Hence $h(F_p)$ is invariant under $g$ in the adjoint representation, exactly if $g$ is in the normalizer of $H^+_p$. First we consider the case when $H^+_p$ is not a normal subgroup of $G(F_p)$. Then there is at least one element $\pi_p(g_0) \in \pi_p(A)$ whose adjoint action does not leave $h(F_p)$ invariant. Let $u \in h(F_p)$ be such that $\pi_p(g_0)u\pi_p(g_0)^{-1} \notin h(F_p)$ and let $v \in g(F_p)$ be orthogonal to $h(F_p)$ with respect to the non-degenerate bilinear form $\langle x, y \rangle = Tr(xy)$ and such that $Tr(\pi_p(g_0)u\pi_p(g_0)^{-1})v = 1$. This settles the claim. Now consider the case when $H^+_p \subset G(F_p)$. If $(p) = P_1 \cdots P_k$ is the factorization of $(p)$ over $K$, then $G(F_p)$ is isomorphic to $SL_d(O_K/P_1) \times \ldots \times SL_d(O_K/P_k)$, and $H^+_p$ must be the direct product of some of these factors. Consider a direct factor
one of the following holds:

There are constants $C$ and $\delta$ depending only on $K$, and for each $H < SL_d(\mathcal{O}_K(q))$ there is an $H^2 < H$ with $[H : H^2] < C^n$ such that at least one of the following holds:

\[ \psi_1(X,Y), \ldots, \psi_M(X,Y) \in \mathbb{Z}[X,Y], \]
\[ \psi'_1(X,Y), \ldots, \psi'_{r'^2d^2-r(d^2-1)}(X,Y) \in \mathbb{Z}[X,Y], \]
\[ \psi''_1(X,Y), \ldots, \psi''_{r''^2d^2-r(d^2-1)}(X,Y) \in \mathbb{Z}[X,Y], \]
\[ \psi'''(X,Y) \in \mathbb{Z}[X,Y] \]

and a positive integer $0 < D < q^{\delta}$ such that

\[ D = \sum_{i=1}^{M} \eta_i(X,Y)\psi_i(X,Y) \]
\[ + \sum_{i=1}^{r'^2d^2-r(d^2-1)} \varphi_i(X)\psi'_i(X,Y) \]
\[ + \sum_{i=1}^{r''^2d^2-r(d^2-1)} \varphi_i(Y)\psi''_i(X,Y) \]
\[ + (\eta_{g_0}(X,Y) - 1)\psi'''(X,Y). \]

Substituting the solution of (4) over $\mathbb{F}_p$ for all $p|q_{g_0}$, we see that $q_{g_0}|D$, a contradiction if $\delta$ is small enough. \( \square \)

**Corollary 7.** There are constants $\delta$ and $C$ depending only on $K$, and for each $H < SL_d(\mathcal{O}_K(q))$ there is an $H^2 < H$ with $[H : H^2] < C^n$ such that at least one of the following holds:
1. There is an embedding $\sigma : K \to C$ and a proper subspace $V \subset \mathfrak{sl}_d(C)$ such that if $h \in \mathcal{L}_d(H^2)$, then

$$\sigma(h)V\sigma(h^{-1}) = V.$$  

(5)

2. There are two embeddings $\sigma_1, \sigma_2 : K \to C$ and an invertible linear transformation $T : \mathfrak{sl}_d(C) \to \mathfrak{sl}_d(C)$ such that

$$T(\sigma_1(h)v\sigma_1(h^{-1})) = \sigma_2(h)T(v)\sigma_2(h^{-1})$$

for any $h \in \mathcal{L}_d(H^2)$ and $v \in \mathfrak{sl}_d(C)$.

Proof. Choose $\delta$ to be $1/r(d^2 - 1)$ times the $\delta$ in Proposition 4. Then there are $u, v \in g(C)$ and there is a $g_0 \in G(Q)$ such that $\text{Tr}(\alpha(h)u\alpha(h^{-1})v) = 0$ for

$$h \in \prod_{r(d^2 - 1)} \mathcal{L}_d(H^2) \subset \mathcal{L}_{dr(d^2 - 1)}(H^1),$$

while $\text{Tr}(g_0ug_0^{-1}v) = 1$. Let $U_l$ be the linear span of $\{\alpha(g)u\alpha(g^{-1}) \mid g \in \prod_l \mathcal{L}_d(H^2)\}$ in $g(C)$. Comparing dimensions, we see that for some $l \leq r(d^2 - 1)$ we have $U_l = U_{l+1}$, and then it is invariant under $\alpha(\mathcal{L}_d(H^2))$ in the adjoint representation. Write $U = U_1$. Then for any $x \in U$, we have $\text{Tr}(xv) = 0$, hence $g_0ug_0^{-1} \notin U$, and $U$ is not invariant under the full group $G(C)$ in the adjoint representation.

Consider the embedding $\alpha : K \to Mat_r(Q)$. Let $a \in K$ be a generator of $K$ over $Q$. Note that the minimal polynomial of $\alpha(a)$ over $Q$ is the same as the minimal polynomial of $\alpha(a)$ in $Mat_r(Q)$. This polynomial has $r$ different roots $\sigma_1(a), \ldots, \sigma_r(a)$ in $C$, hence there is a basis over $C$ in which $\alpha(a)$ is diagonal. Any element $b \in K$ can be expressed as the value at $a$ of a polynomial with rational coefficients. Thus in that basis the matrix of $b$ is $\text{diag}(\sigma_1(b), \ldots, \sigma_r(b))$.

Therefore there is an appropriate basis in which any $g \in G(C)$ is a block diagonal matrix with $\sigma_1(g), \ldots, \sigma_r(g)$ along the diagonal. This gives rise to an isomorphism $\beta : G(C) \to SL_d(C)^r$ such that $\sigma = \beta \circ \alpha$. $\beta$ also induces an isomorphism between the Lie algebras $g(C)$ and $sl_d(C)^r$, denote by $W$ the image of $U$.

Assume that $W$ is a subspace of minimal dimension which is invariant under $[\mathcal{L}_d(H^2)]$ in the adjoint representation, but not under the whole group $SL_d(C)^r$. Denote by $g_1(C), \ldots, g_r(C)$ the $r$ copies of $sl_d(C)$ in $sl_d(C)^r$ and denote by $\pi_i$ the projection to $g_i(C)$. For $1 \leq i \leq r$, the spaces $\pi_i(W)$ and $W \cap g_i(C)$ are invariant under $\sigma_i[\mathcal{L}_d(H^2)]$ in the adjoint representation, hence 1, holds if the dimension of any of the above spaces is strictly between 0 and $d^2 - 1$. Suppose that this is not the case. Since $W$ is not the direct sum of some $g_i(C)$, we may assume that say $W \cap g_1(C) = \{0\}$ and $\pi_1(W) = g_1(C)$. By the minimality of the dimension of $W$, $\text{Ker}(\pi_1) \cap W$ must be the direct sum of some $g_i(C)$. Since dim $W > \dim \text{Ker}(\pi_1) \cap W$, we can assume that say $\pi_2(\text{Ker}(\pi_1) \cap W) = \{0\}$ and $\pi_2(W) = g_2(C)$. Then $T = \pi_2 \circ \pi_1^{-1}$ is well-defined and satisfies 2. □
Recall that we are given a symmetric \( S \subset SL_d(\mathcal{O}_K) \) which generates the subgroup \( \Gamma \). We will choose an appropriate \( S' \subset \Gamma \) and study the random walk on \( G(\langle S' \rangle, S') \), where \( \langle S' \rangle \) is the subgroup generated by \( S' \). In particular, we prove an exponential decay for the probability that after \( k \) steps we are in the subgroup of \( SL_d(\mathcal{O}_K) \) whose elements satisfy (5) for some fixed \( V \) or in the one whose elements satisfy (6) for some fixed \( T \).

**Proposition 8.** Assume that \( \hat{\sigma}(\Gamma) \) is Zariski dense in \( SL_d(\mathbb{C})^r \). Let \( V \) be a proper subspace of \( sl_d(\mathbb{C}) \), and let \( \sigma : K \to \mathbb{C} \) be an embedding, denote by \( H_V \) the subgroup of elements \( h \in SL_d(\mathcal{O}_K) \) for which (5) holds. Then

\[
\chi_{S'}^{(k)}(H_V) \ll c^k
\]

with some constant \( c < 1 \) depending only on \( S \).

**Proposition 9.** Assume that \( \hat{\sigma}(\Gamma) \) is Zariski dense in \( SL_d(\mathbb{C})^r \). Then there is a symmetric set \( S' \subset \Gamma \), and a constant \( c < 1 \) depending only on \( S \) such that the following holds. Let \( \sigma_1, \sigma_2 \) be two different embeddings of \( K \) into \( \mathbb{C} \) and let \( T \) be an invertible linear transformation on \( sl_d(\mathbb{C}) \). Denote by \( H_T \) the subgroup of elements \( h \in SL_d(\mathcal{O}_K) \) for which (6) holds. Then

\[
\chi_{S'}^{(k)}(H_T) \ll c^k.
\]

Proposition 8 can be proved as it is outlined in [6, Section 9.], we omit the details. A weaker form analogous to Proposition 9, which is sufficient for our purposes, can be proved by the same method as we prove Proposition 9 below.

Let \( A \subset \Gamma \) be a subset that freely generates a subgroup. By abuse of notation, on a word \( w \) over \( A \cup \tilde{A} \), we mean a finite sequence \( g_1g_2 \cdots g_k \), where \( g_1, \ldots, g_k \in A \cup \tilde{A} \). Recall that \( \tilde{A} \) is the set of inverses of all elements of \( A \). We will refer to the elements of \( A \cup \tilde{A} \) as letters. We say that \( w \) is reduced if \( g_i g_{i+1} \neq 1 \) for any \( 1 \leq i < k \). There is a natural bijection between the set of reduced words and the group \( \langle A \rangle \) generated by \( A \subset \Gamma \). For the sake of clarity we write \( w_1w_2 \) for concatenation of the sequences \( w_1 \) and \( w_2 \) and \( w_1w_2 \) for the product in \( \Gamma \), i.e. for concatenation followed by all possible reductions. Denote by \( B_l \) the set of reduced words of length \( l \). Note that \( |B_l| = 2m(2m - 1)^{l-1} \) for \( l \geq 1 \).

**Lemma 10.** Let notation be as above, and suppose that \( H \lhd \langle A \rangle \) is a subgroup such that for any \( h \in \langle A \rangle \), there is a letter \( g_0 \in A \cup \tilde{A} \) such that \( w \notin hh^{-1} \) whenever \( w \) is a reduced word starting with \( g_0 \). Then we have

\[
|B_l \cap H| \leq (2m - 1)^{l/2 + 1}(2m - 2)^{l/2 - 1}.
\]

We remark that the condition for \( h = 1 \) can be interpreted as follows. We can remove one edge incident to 1 from the Schreier graph of \( H \setminus G \) such that we get two connected components and one of these is a tree.
Assume further that $T$ is projective space. For a vector $w$ we study the action of $\text{SL}_Q$ of $\| \cdot \|$ where $T$ is proximal, if $n$ is unique up to a constant multiple. Define the distance on $P$ as the norm coming from the standard Hermitian form. We recall $\rho_1$ that can be naturally on $P$. Let $\bar{w} \in S_1 \cap H$ one by one, then at the first $\lceil l/2 \rceil$ steps we have at most $2l - 2$ choices with possibly one exception, when we might have $2l - 1$, this gives the claim.

Now assume that $|w_0| < |w_1| \leq \lceil l/2 \rceil - 1$, but if $w_0 = 1$, we allow $w_1 = 1$. Using the assumption for $h = w_1^{-1}$, we get a letter $g_0$ such that if $g_0w_2$ is a reduced word (i.e. the first letter of $w_2$ is not $g_0^{-1}$), then $g_0w_2 \notin w_1^{-1}Hw_1$. We show that the last letter of $w_1$ is not $g_0^{-1}$. If $w_1$ is not the empty word, it is longer than $w_0$, hence there is a word $u \in H$, $w_1$ is not a prefix of which. Now if $g_0^{-1}$ was the last letter of $w_1$, we would have $w_1^{-1}uw_1 \in w_1^{-1}Hw_1$ which begins with $g_0$, a contradiction.

Obviously we can not continue $w_1$ with the inverse of its last letter to get a reduced word. We show that we can not continue it with $g_0$ either to get one in $B_1 \cap H$. Assume to the contrary that for some $w_2$, $w_1, g_0, w_2$ is a reduced word in $B_1 \cap H$. Then $g_0w_2w_1 \in w_1^{-1}Hw_1$ and the length of $w_1$ is less than the length of $w_2$, hence $g_0w_2w_1$ starts with $g_0$, a contradiction.

Let $V$ be a vectorspace over $\mathbb{C}$, and denote by $P(V)$ the corresponding projective space. For a vector $v \in V$ (for a subspace $W \subset V$) denote by $\bar{v}$ its projection to $P(V)$. Any invertible linear transformation $T$ of $V$ acts naturally on $P(V)$, this action will be denoted by the same letter. We say that $T$ is proximal, if $V$ is spanned by an eigenvector $z_T$ and an invariant subspace $V_T$ of $T$ and the eigenvalue corresponding to $z_T$ is strictly larger than any other eigenvalue of $T$. In short, $T$ is proximal if it has a unique simple eigenvalue of maximal modulus. It is clear that whenever $z_T$ and $V_T$ exist, $V_T$ is unique and $z_T$ is unique up to a constant multiple. Define the distance on $P(V)$ by

$$d(\bar{x}, \bar{y}) = \frac{\|x \wedge y\|}{\|x\| \|y\|},$$

where $\| \cdot \|$ is the norm coming from the standard Hermitian form. We recall from Tits [32] a simple criterion for a transformation $T$ to be proximal. Let $Q \subset P(V)$ be compact and assume that $T(Q)$ is contained in the interior of $Q$. Assume further that $d(T(x), T(y)) < d(x, y)$ for $x, y \in Q$. Then $T$ is proximal and $\bar{z}_T \in Q$, see [32, Lemma 3.8 (ii)].

Let notation be the same as in Proposition 9. For $i \in \{1, 2\}$, denote by $\rho_i$ the representation of $\text{SL}_d(\mathcal{O}_K)$ on $\mathfrak{s}l_d(\mathbb{C})$ defined by $\rho_i(h)v = \sigma_i(h)v\sigma_i(h^{-1})$ for $v \in \mathfrak{s}l_d(\mathbb{C})$ and $h \in \text{SL}_d(\mathcal{O}_K)$. We study the action of $\text{SL}_d(\mathcal{O}_K)$ on the space $P(\mathfrak{s}l_d(\mathbb{C})) \times P(\mathfrak{s}l_d(\mathbb{C}))$ via $\rho_1 \oplus \rho_2$. If $T$ is an invertible linear transformation of $\mathfrak{s}l_d(\mathbb{C})$ and $h \in H_T$ is an element
such that \( \rho_1(h) \) and \( \rho_2(h) \) are both proximal, then

\[
T(\tilde{z}_{\rho_1(h)}) = \tilde{z}_{\rho_2(h)}
\]

(7)
clearly. Our aim is to find a subset \( A \subset \Gamma \) such that \( A \) freely generates a subgroup of \( SL_d(\mathcal{O}_K) \) and for any linear transformation \( T \) of \( \mathfrak{sl}_d(\mathbb{C}) \), there is a letter \( g_0 \in A \cup \bar{A} \) such that (7) fails when \( h = w \) is a reduced word starting with \( g_0 \). Then Proposition 9 will follow easily from Lemma 10.

We say that \( A \subset SL_d(\mathcal{O}_K) \) is generic, if for any \( g \in A \cup \bar{A} \), \( \rho_1(g) \) and \( \rho_2(g) \) are both proximal, and the following hold:

(i) for every \( g_1, g_2 \in A \cup \bar{A} \) with \( g_1g_2 \neq 1 \) and \( i \in \{1, 2\} \), we have \( z_{\rho_i(g_1)} \notin V_{\rho_i(g_2)} \),

(ii) for any proper subspace \( V \) of \( \mathfrak{sl}_d(\mathbb{C}) \) of dimension \( k \) and \( i \in \{1, 2\} \), we have

\[
|\{ g \in A \cup \bar{A} \mid z_{\rho_i(g)} \in V \}| \leq k + 1,
\]

(iii) for any linear transformation \( T \) on \( \mathfrak{sl}_d(\mathbb{C}) \), we have

\[
|\{ g \in A \cup \bar{A} \mid T(\tilde{z}_{\rho_1(g)}) = \tilde{z}_{\rho_2(g)} \}| \leq d^2 + 1.
\]

Note that \( \mathfrak{sl}_d(\mathbb{C}) \) is of dimension \( d^2 - 1 \). Actually the above definition would be more natural if we replaced the right hand sides of the inequalities in (ii) and (iii) by \( k \) and \( d^2 \) respectively, however doing so would make the next proof slightly more complicated. We prove the existence of generic sets in

**Lemma 11.** Assume that \( \bar{\sigma}(\Gamma) \) is Zariski dense in \( SL_d(\mathbb{C}) \). Then for \( m \) positive integer, there is a generic set \( A_m \subset \Gamma \) of cardinality \( m \).

**Proof.** Goldsheid and Margulis [16] proves (see also sections 3.12-3.14 in Abels, Margulis and Soifert [1]) that if a real algebraic subgroup of \( GL_d(\mathbb{R}) \) is strongly irreducible (i.e. does not leave a finite union of proper subspaces invariant) and contains a proximal element, then a Zariski dense subgroup of it also contains a proximal element. If \( \sigma_1 \) is a real embedding, then it follows from the Zariski density of \( \sigma_1(\Gamma) \) in \( SL_d(\mathbb{R}) \), that there is an element \( g_0 \in \Gamma \) such that \( \sigma_1(g_0) \) is proximal. If \( \sigma_1 \) is complex, then let \( \bar{\sigma}_1 \) denote its complex conjugate. Since \( (\sigma_1 \oplus \bar{\sigma}_1)(\Gamma) \) is Zariski dense in \( SL_d(\mathbb{C}) \times SL_d(\mathbb{C}) \), we get that \( \sigma_1(\Gamma) \) is Zariski dense in \( SL_d(\mathbb{C}) \) over the reals as well, i.e. considered as a subgroup of \( SL_{2d}(\mathbb{R}) \).

Consider \( \mathbb{C}^d \) as a real vectorspace, and take the wedge product \( \mathbb{C}^d \wedge \mathbb{C}^d \). Denote by \( U \) the subspace spanned by the images of complex lines in \( \mathbb{C}^d \), this is also the subspace fixed by the linear transformation induced from the transformation multiplication by \( i \) on \( \mathbb{C}^d \). It is clear that \( SL_d(\mathbb{C}) \) (as a real group) acts on \( U \) strongly irreducibly and proximally in the natural way, hence there is an element \( g_0 \in \Gamma \) such that \( \sigma_1(\Gamma) \) is proximal on \( U \). This implies in turn that \( \sigma_1(\Gamma) \) is proximal on \( \mathbb{C}^d \) now considered as a complex vectorspace. Denote by \( \sigma_i' \) (for \( i \in \{1, 2\} \)) the representation of \( \Gamma \) which assigns the transpose inverse of the matrix assigned by \( \sigma_i \). Applying [1, Lemma 5.15] for the representation
\[ \sigma_1 \oplus \sigma_1' \oplus \sigma_2 \oplus \sigma_2', \] we get an element \( g_0 \in \Gamma \) such that \( \sigma_1(g_0), \sigma_1(g_0^{-1}), \sigma_2(g_0) \) and \( \sigma_2(g_0^{-1}) \) are proximal simultaneously. This imply in turn that \( \rho_1(g_0), \rho_1(g_0^{-1}), \rho_2(g_0) \) and \( \rho_2(g_0^{-1}) \) are also proximal.

We can set \( A_1 = \{ g_0 \} \) and get the claim for \( m = 1 \). We proceed by induction, assume that we can construct \( A_m \) for some \( m \geq 1 \). We try to find an element \( h \in \Gamma \) such that \( A_{m+1} = A_m \cup \{ h g_0 h^{-1} \} \) is generic. Clearly \( \tilde{z}_{\rho_1(h)g_0h^{-1}} = \rho_1(h)\tilde{z}_{\rho_1(g_0)} \). One condition \( h \) needs to satisfy is that neither \( \rho_1(h)\tilde{z}_{\rho_1(g_0)} \) nor \( \rho_1(h)\tilde{z}_{\rho_1(g_0^{-1})} \) should belong to those proper subspaces \( V \) of \( \mathfrak{sl}_d(\mathbb{C}) \) for which

\[ |\{ g \in A_m \cup \tilde{A}_m \mid \tilde{z}_{\rho_1(g)} \in V \}| \geq \dim V. \]

There are a finite number of such subspaces, hence this is a Zariski open condition on \( \sigma_1(h) \). It can be seen in a similar fashion that \( A_{m+1} \) is generic if \( (\sigma_1(h), \sigma_2(h)) \) belongs to a certain Zariski dense open subset of \( SL_d(\mathbb{C}) \times SL_d(\mathbb{C}) \), and the lemma follows by induction.

We remark that it is easy to see from the proof that \( A_m \) can be chosen in such a way that it is generic with respect to any pair of embeddings \( \sigma_1 \) and \( \sigma_2 \).

**Lemma 12.** Let \( A \subset \Gamma \) be a generic set of cardinality at least \((d^2 + 2)/2\). Then for each \( g \in A \cup \tilde{A} \) and \( i \in \{1, 2\} \), there is a neighborhood \( U_g^{(i)} \subset P(\mathfrak{sl}_d(\mathbb{C})) \) of \( \tilde{z}_{\rho_1(g)} \) with the following property. For any invertible linear transformation \( T \) on \( \mathfrak{sl}_d(\mathbb{C}) \) there is an \( g \in A \cup \tilde{A} \) such that \( T(U_g^{(1)}) \cap U_g^{(2)} = \emptyset \).

First we recall [11, Proposition 2.1]. Let \( T_1, T_2, \ldots \) be a sequence of invertible linear transformations on \( \mathfrak{sl}_d(\mathbb{C}) \). There is a not necessarily invertible linear transformation \( T \neq 0 \) and a subsequence of \( T_1, T_2, \ldots \) that considered as maps on \( P(\mathfrak{sl}_d(\mathbb{C})) \) converge uniformly to \( T \) on compact subsets of \( P(\mathfrak{sl}_d(\mathbb{C})) \setminus \text{Ker}(T) \).

**Proof of Lemma 12.** Assume to the contrary that the claim is false. Then there is a sequence \( \{ T_k \} \) of linear transformations such that for any choice of the neighborhoods \( U_g^{(i)} \) \( (i \in \{1, 2\} \) and \( g \in A \cup \tilde{A} \), we have \( T_k(U_g^{(1)}) \cap U_g^{(2)} \neq \emptyset \) for \( k \) large enough. By the aforementioned result, we may assume that \( \{ T_k \} \) converges uniformly to a linear transformation \( T \) on compact subsets of \( P(\mathfrak{sl}_d(\mathbb{C})) \setminus \text{Ker}(T) \). This implies that if \( z_{\rho_1(g)} \notin \text{Ker}(T) \), then \( T(\tilde{z}_{\rho_1(g)}) = \tilde{z}_{\rho_2(g)} \). When \( T \) is invertible, this violates (iii) in the definition of generic sets. If \( T \) is not invertible, we get a contradiction with (ii) of that definition, either for \( V = \text{Ker}(T) \) or for \( V = \text{Im}(T) \), and the lemma follows.

**Lemma 13.** Let \( A \subset \Gamma \) be generic, and for each \( g \in A \cup \tilde{A} \) and \( i \in \{1, 2\} \) let \( U_g^{(i)} \subset P(\mathfrak{sl}_d(\mathbb{C})) \) be a sufficiently small neighborhood of \( \tilde{z}_{\rho_1(g)} \). Then there is a positive integer \( M \) such that \( \{ g^M \mid g \in A \} \) freely generates a subgroup of \( \Gamma \) and if \( h = g_1^M g_2^M \cdots g_k^M \) is a reduced word, then \( \rho_1(h) \) and \( \rho_2(h) \) are proximal with \( \tilde{z}_{\rho_1(h)} \in U_g^{(i)} \).
From general properties of Markov chains (see [33, Lemma 1.9]) it follows that

\[ d(\rho(g^M)\bar{x}, \rho(g^M)\bar{y}) < d(\bar{x}, \bar{y}) \quad \text{for} \quad x, y \in Q_g \quad \text{and} \]

\[ U_{g'} \subset Q_g \quad \text{if} \quad gg' \neq 1. \]

Here we used property (i) of generic sets. If \( M \) is large enough we clearly have \( \rho(g^M)Q_g \subset U_g \) also. By induction, we see that if \( h = g_1^M \cdots g_k^M \) is a reduced word then \( \rho(h)Q_{g_k} \subset U_{g_1} \) and \( d(\rho(h)\bar{x}, \rho(h)\bar{y}) < d(\bar{x}, \bar{y}) \) for \( \bar{x}, \bar{y} \in Q_{g_k} \). If \( g_1g_k \neq 1 \), then \( U_{g_k} \subset Q_{g_k} \) and the claim follows for \( h \) by the aforementioned lemma of Tits [32, Lemma 3.8 (ii)]. If \( g_1g_k = 1 \), then write \( h = g_1^M h' g_1^{-M} \). If \( h' \) is proximal with \( \bar{z} = \rho(h') \in U_{g_2} \), then \( h \) is also proximal with \( \bar{z} = \rho(h) \bar{z} = \rho(g_1)\bar{z} \rho(h') \), and the claim follows by induction. Now \( \{ g^M \mid g \in A \} \) generates freely a group since the identity is not proximal.

Proof of Proposition 9. Let notation be as in the statement of the proposition. Let \( A \) be a generic set of cardinality \( m \geq (d^2 + 2)/2 \), and set \( S' = \{ g^M \mid g \in A \cup \tilde{A} \} \), where \( M \) is the same as in Lemma 13. For \( g \in S' \) and \( i \in \{ 1, 2 \} \) let \( U_g^{(i)} \) be a neighborhood of \( \bar{z} = \rho(g) \) which is sufficiently small for Lemmata 12 and 13. Then there is an element \( g_9 \in S' \) such that \( T(U_{g_9}^{(1)}) \cap U_{g_9}^{(2)} = \emptyset \). For \( h \in H_T \) we clearly have \( T_{\rho(h)} \bar{z} = \rho(h) \bar{z} = \rho(g_1)\bar{z} \rho(h') \), so if \( h \) is a reduced word of form \( g_1 \cdots g_k \), then \( g_1 \neq g_0 \) by Lemma 13. If \( h \in SL_d(\mathbb{O}_K) \), a similar result holds for \( hH_T h^{-1} = H_{\rho_2(h)T\rho_1(h^{-1})} \). Therefore by Lemma 10, we have

\[ |B_1 \cap H_T| \leq (2m - 1)^{l/2 + 1}(2m - 2)^{l/2 - 1}, \]

where \( B_1 \) is the set of reduced words of length \( l \) over the alphabet \( S' \).

Set \( P_k(l) = \chi_{S'}^{(2k)}(w) \), where \( w \in B_1 \). Since \( |B_1| = 2m(2m - 1)^{l-1} \) for \( l \geq 1 \),

\[ 1 = P_k(0) + \sum_{l \geq 1} 2m(2m - 1)^{l-1} P_k(l). \quad (8) \]

By a result of Kesten [22, Theorem 3.], we have

\[ \limsup_{k \to \infty} (P_k(0))^{1/k} = (2m - 1)/m^2. \]

From general properties of Markov chains (see [33, Lemma 1.9]) it follows that

\[ P_k(0) \leq \left( \frac{2m - 1}{m^2} \right)^k. \]

Since \( \chi_{S'}^{(2k)} \) is symmetric, we have \( P_k(0) = \sum_g \chi_{S'}^{(k)}(g) \), hence \( P_k(l) \leq P_k(0) \) for
all \( l \) by the Cauchy-Schwartz inequality. Now we can write

\[
\chi^{(2k)}_{S'}(H_T) = \sum_l |B_l \cap H_T| P_k(l)
\]
\[
\leq \sum_l (2m - 1)^{l/2} + (2m - 2)^{l/2 - 1} P_k(l)
\]
\[
\leq \sum_{l \leq k/10} (2m - 1)^{l/2} + (2m - 2)^{l/2 - 1} \left( \frac{2m - 1}{m^2} \right)^k
\]
\[
\leq \left( \frac{2m - 1}{2m} \right)^{k/20} \sum_{l \geq k/10} 2m(2m - 1)^{l-1} P_k(l)
\]
\[
< \left( \frac{2m - 1}{2m} \right)^{k/2} + \left( \frac{2m - 1}{2m} \right)^{k/20},
\]

which was to be proven. The inequality between the third and fourth lines follows form (8).

Proof of Theorem 2. Let \( S' \) be the same as in Proposition 9 and let \( C \) and \( \delta \) be the same as in Corollary 7. As we remarked after Lemma 11, we can choose \( S' \) in such a way that it works for any pair of embeddings \( \sigma_1 \) and \( \sigma_2 \). There is a constant \( c \) depending on the set \( S' \) such that

\[
\log \| \hat{\sigma}(g) \| \leq cl \quad \text{for} \quad g \in \prod_l S'.
\]

Then for \( l = \delta \log[SL_d(O_k/(q)) : H^2]/c \), we have

\[
\pi_q[\chi_{S'}^{(l)}(H^2)] = \chi_{S'}^{(l)}(L_\delta(H^2)).
\]

Combining Corollary 7 with either Proposition 8 or Proposition 9 we get

\[
\chi_{S'}^{(l)}(L_\delta(H^2)) \ll [SL_d(O_k/(q)) : H^2]^{-\delta c'}
\]

with some \( c' > 0 \). If \( l \) is even, then by the symmetry of \( S' \),

\[
(\pi_q[\chi_{S'}^{(l/2)}](gH^2))^2 \leq \pi_q[\chi_{S'}^{(l)}](H^2)
\]

for any coset \( gH^2 \), and by \([ H : H^2 ] < C^n \) we then have

\[
\pi_q[\chi_{S'}^{(l/2)}](H) \leq C^n(\pi_q[\chi_{S'}^{(l)}](H^2))^{1/2}.
\]

If \( l_1 \leq l_2 \), then clearly

\[
\pi_q[\chi_{S'}^{(l_2)}](H) \leq \max_g \pi_q[\chi_{S'}^{(l_1)}](gH).
\]

Now it is straightforward to get the theorem by putting together the above inequalities. \qed
3 A product theorem

Recall that \( H_1 \lesssim_L H_2 \) is a shorthand for \( [H_1 : H_1 \cap H_2] \leq L \). We denote by \( Z(G) \) the center of the group \( G \), by \( C(g) \) the centralizer of the element \( g \in G \) and by \( N_G(H) \) the normalizer of the subgroup \( H < G \). In this section \( K \) is not a number-field, it usually stands for a large positive real number. We begin by listing the assumptions already mentioned in Theorem 3. When we say that something depends on the constants appearing in the assumptions (A1)–(A5) we mean \( L \) and the function \( \delta(\varepsilon) \) for which (A4) holds.

(A0) \( G = G_1 \times \cdots \times G_n \) is a direct product, and the collection of the factors satisfy (A1)–(A5) for some sufficiently large constant \( L \).

(A1) There are at most \( L \) isomorphic copies of the same group in the collection.

(A2) Each \( G_i \) is quasi-simple and we have \( |Z(G_i)| < L \).

(A3) Any nontrivial representation of \( G_i \) is of dimension at least \( |G_i|^{-1/L} \).

(A4) For any \( \varepsilon > 0 \), there is a \( \delta > 0 \) such that the following holds. If \( \mu \) and \( \nu \) are probability measures on \( G_i \) satisfying

\[
\|\mu\|_2 > |G_i|^{-1/2+\varepsilon} \quad \text{and} \quad \mu(gH) < |G_i|^{-\varepsilon}
\]

for any \( g \in G_i \) and for any proper \( H < G_i \), then

\[
\|\mu * \nu\|_2 \ll \|\mu\|_2^{1/2} + \|\nu\|_2^{1/2}.
\]

(A5) For some \( m < L \), there are classes \( \mathcal{H}_0, \mathcal{H}_1, \ldots, \mathcal{H}_m \) of subgroups of \( G_i \) having the following properties.

(i) \( \mathcal{H}_0 = \{Z(G)\} \).

(ii) Each \( \mathcal{H}_j \) is closed under conjugation by elements of \( G_i \).

(iii) For each proper \( H < G_i \) there is an \( H^2 \in \mathcal{H}_j \) for some \( j \) with \( H \lesssim_L H^2 \).

(iv) For every pair of subgroups \( H_1, H_2 \in \mathcal{H}_j, \ H_1 \neq H_2 \) there is some \( j' < j \) and \( H^3 \in \mathcal{H}_{j'} \) for which \( H_1 \cap H_2 \lesssim_L H^3 \).

We remark that considering the induced representation, (A3) implies that for any proper subgroup \( H < G_i \) we have

\[
[G_i : H] > |G_i|^{1/L}.
\]

One may think about (A5) that there is a notion for dimension of the subgroups of \( G_i \).

In the next section we show that Theorem 3 is a simple corollary of the following seemingly weaker result.
Proposition 14. Let $G$ be a group satisfying $(A0)$–$(A5)$. For any $\varepsilon > 0$ there is a $\delta > 0$ depending only on $\varepsilon$ and the constants in assumptions such that the following holds. If $S \subset G$ is symmetric such that $|S| < |G|^{1-\varepsilon}$ and $\chi_S(gH) < |G : H|^{-\varepsilon}|G|^\delta$ for any $g \in G$ and any proper $H < G$, then $|\prod_3 S| \gg |S|^{1+\delta}$.

3.1 Proof of Theorem 3 using Proposition 14

We make use of the following result which appeared first implicitly in the proof of Proposition 2 in Bourgain, Gamburd [5].

Lemma 15 (Bourgain, Gamburd). Let $\mu$ and $\nu$ be two probability measures on an arbitrary group $G$ and let $K > 2$ be a number. If

$$\|\mu * \nu\|_2 > \frac{\|\mu\|_2^{1/2}\|\nu\|_2^{1/2}}{K}$$

then there is a symmetric set $S \subset G$ with

$$\frac{1}{K^R\|\mu\|_2^2} \ll |S| \ll \frac{K^R}{\|\mu\|_2^2}$$

$$|\prod_3 S| \ll K^R|S|$$

and

$$\min_{g \in S} (\tilde{\mu} * \mu)(g) \gg \frac{1}{K^R|S|},$$

where $R$ and the implied constants are absolute.

Proof. We include the proof only for the sake of completeness, the argument is essentially the same as in the proof of [5, Proposition 2].

First we note that by Young’s inequality $\|\mu * \nu\|_2 \leq \|\mu\|_2$ and hence $\|\nu\|_2 < K^2\|\mu\|_2$ and similarly $\|\mu\|_2 < K^2\|\nu\|_2$. Let $\lambda$ be a nonnegative measure with $\|\lambda\|_2 \leq 1$ and $\|\lambda\|_2 \ll c$. Observe that if $\lambda(g) \geq K'c$ for some $K'$ every $g \in \text{supp} \lambda$, then $\|\lambda\|_2 \geq K'c\|\lambda\|_1$, hence $\|\lambda\|_1 < 1/K'$. Similarly, if $\lambda(g) \leq c/K'$ for all $g$, then $\|\lambda\|_2 < c/K'$. Now define the sets

$$A_i = \{g \in G | 2^{i-1}\|\mu\|_2^2 < \mu(g) \leq 2^i\|\mu\|_2^2\}$$

and

$$B_i = \{g \in G | 2^{i-1}\|\nu\|_2^2 < \nu(g) \leq 2^i\|\nu\|_2^2\}$$

for $|i| < 10 \log K$. By Young’s inequality,

$$\|\mu \ast \nu\|_2 \leq \sum_{|i|,|j| \leq 10 \log K} 2^{i+j}\|\mu\|_2^2\|\nu\|_2^2|A_i|B_j|\chi_{A_i} \ast \chi_{B_j}|_2 + K^{-5}(\|\mu\|_2 + \|\nu\|_2),$$

hence there must be a pair of indices $i, j$ such that

$$2^{i+j}\|\mu\|_2^2\|\nu\|_2^2|A_i|B_j|\chi_{A_i} \ast \chi_{B_j}|_2 \gg \frac{\|\mu\|_2^{1/2}\|\nu\|_2^{1/2}}{K \log^2 K}. \quad (11)$$
By construction, for \( g \in A_i \) we have
\[
2^i \| \mu \|_2^2 \gg \mu(g) \gg 2^i \| \mu \|_2^2,
\]
and by (11) and Young’s inequality, \( 1 \geq \mu(A_i) \gg 1/K^R \). Here, and everywhere \( R \) denotes an absolute constant which need not be the same at different occurrences. These together give
\[
\frac{K^R}{\| \mu \|_2^2} \gg |A_i| \gg \frac{1}{K^R \| \mu \|_2^2}.
\]
We may get the analogous inequalities
\[
\frac{K^R}{\| \mu \|_2^2} \gg |B_j| \gg \frac{1}{K^R \| \mu \|_2^2},
\]
in a similar way and using the relations between \( \| \mu \|_2 \) and \( \| \nu \|_2 \). Applying our inequalities to (11), we get
\[
\| \chi_{A_i} \ast \chi_{B_j} \|_2^2 \gg \frac{1}{K^R |A_i|^{1/2} |B_j|^{1/2}}.
\]
We invoke the non-commutative version of the Balog-Szemerédi-Gowers theorem proven by Tao [29, Theorem 5.2], (note that we use a different normalization). This gives subsets \( A \subset A_i \) and \( B \subset B_i \) with \( |A| \gg |A_i|/K^R \) and \( |A.B| \ll K^R |A|^{1/2} |B|^{1/2} \). Ruzsa’s triangle inequality [29, Lemma 3.2] for the sets \( A \) and \( \tilde{A} \) gives
\[
|A.\tilde{A}| \ll K^R |A| \ll K^R |S|.
\]
In the proof of Proposition 4.5 of [29] the set \( S \) is defined by
\[
\{ g \in G \mid |A \cap (A.\{ g \})| > |A|/C \}
\]
with \( C = 2 |A.\tilde{A}|/|A| \). For \( g \in S \), we have
\[
(\tilde{\mu} * \mu)(g) \geq 2^{2i-2} |\mu|_2^4 |A \cap (A.\{ g \})| \gg \frac{1}{K^R |S|}.
\]
The expression in the middle is bounded below by \( |\mu|_2^2/K^R \) also, which gives the required upper bound for \( |S| \), since \( \| \tilde{\mu} * \mu \|_1 = 1 \).

**Proof of Theorem 3.** Assume that the conclusion of the theorem fails, i.e. that there is an \( \varepsilon \) such that for any \( \delta \) there are probability measures \( \mu \) and \( \nu \) with
\[
\| \mu \|_2 > |G|^{-1/2+\varepsilon} \quad \text{and} \quad \mu(gH) < |G:H|^{-\varepsilon}
\]
for any \( g \in G \) and for any proper \( H < G \), and yet
\[
\| \mu \ast \nu \|_2 \geq \| \mu \|_2^{1/2+\delta} \| \nu \|_2^{1/2}.
\]

19
Take $K = \|\mu\|^2$ in Lemma 15. Note that by the third property of the set, $S$ we have

$$\chi_S(gH) \ll K^R \mu * \mu(gH) \leq K^R \max_{h \in G} \mu(hH) \ll |G|^R |G : H|^{-\varepsilon}.$$ 

Now $|\prod S| \ll K^{R} |S|$ contradicts Proposition 14, if $\delta$ is small enough.

### 3.2 Proof of Proposition 14

Throughout sections 3.2–3.4, we assume that $G = G_1 \times \ldots \times G_n$ satisfies (A0)–(A5) with some $L, \varepsilon$ and $S$ are the same as in Proposition 14, and we fix a sufficiently small $\delta$. By sufficiently small, we mean that we are free to use inequalities $\delta < \delta'$, where $\delta'$ is any function of $\varepsilon$ and the constants in (A1)–(A5). We use $c, \delta', \delta''$, etc. to denote positive constants that may depend only on $\varepsilon$ and the constants in (A1)–(A5). These need not be the same at different occurrences. We will also use inequalities of the form

$$Q \log |G_i| < |G_i|^\delta.$$ 

Let $N$ be the product of those factors $G_i$, for which such an inequality fails. Since the same group appears at most $L$ times among the $G_i$, the size of $N$ is bounded. Replace $G$ by $G/N$. For any $H < G/N$, we have $|G/N : H| = |G : HN|$ and if $S$ denotes the projection of $S$ in $G/N$, then we have $|\prod S| \geq |\prod S|$ and $|S| \leq |S||N|$. Hence the theorem for the group $G/N$ implies itself for $G$ with a larger implied constant. Thus we can use (12) without loss of generality.

In a similar fashion we may replace each $G_i$ by $G_i/Z(G_i)$, hence from now on, we assume that all the $G_i$ are simple. This may introduce a factor of size at most $L^n$ which is $< |G|^\delta$ for any $\delta > 0$.

We follow the argument of Bourgain, Gamburd and Sarnak [8, Section 5]. First we introduce some notation. Denote $\pi_i$ for $1 \leq i \leq n$ the projection from $G$ to $G_i$. Set $G_{\leq i} = \times_{j \leq i} G_j$ and denote $\pi_{\leq i}$ the projection from $G$ to $G_{\leq i}$. To the set $S$, we associate a tree of $n + 1$ levels. Level 0 consists of a single vertex, while for $i > 0$ the vertices of level $i$ are the elements of the set $\pi_{\leq i}(S)$, and a vertex $g$ on level $i - 1$ is connected to those vertices on level $i$ which are of the form $(g, h)$ with some $h \in G_i$. By removing some vertices, we can get a regular tree, that is a tree which has vertices of equal degree on each level. More precisely, using [8, Lemma 5.2] we obtain a subset $A \subseteq S$ and a sequence $\{D_i\}_{1 \leq i \leq n}$ of positive integers with $D_i \geq |G_i|^\delta$ or $D_i = 1$ such that for any $g \in \pi_{\leq i-1} A$, we have

$$|\{h \in G_i \mid (g, h) \in \pi_{\leq i}(A)\}| = D_i,$$

and

$$|A| > \prod_{i=1}^n (|G_i|^\delta |G_i|)^{-1} |S| > |G|^{-2\delta} |S|. \quad (13)$$

The second inequality in (13) is of type (12).
We briefly outline the proof. Consider the set $\prod_k A$ for some integer $k$ and the tree associated to it in the way described above. If $g \in \pi_{\leq i-1} (\prod_k A)$ is a vertex on level $i-1$ and $g = g_1 \cdots g_k$ with $g_l \in \pi_{\leq i-1} (A)$, then $(g,h)$ is connected to $g$ for every $h$ in the product-set
\[
\{ h_1 | (g_1, h_1) \in \pi_{\leq i} (A) \} \cdots \{ h_k | (g_k, h_k) \in \pi_{\leq i} (A) \}.
\]
Let $I_s$ be the set of indices $1 \leq i \leq n$ for which $D_i < |G_i|^{1-1/3L}$ (i.e. indices corresponding to small degrees), for such an index, there is hope that we can apply (A4) for $G_i$ and get that the above product-set is of size $D_i^{1+\delta'}$ for some $\delta' > 0$. We make this speculation precise in section 3.3. Set $I_l = \{1, \ldots, n\} \setminus I_s$ (indices corresponding to large degrees), $G_s = \times_{i \in I_s} G_i$ and $G_l = \times_{i \in I_l} G_i$, and denote by $\pi_s$ and $\pi_l$ the projections from $G = G_s \times G_l$ to $G_s$ and $G_l$ respectively.

We get from a result of Gowers [17] that $\pi_l (S.S.S) = G_l$. In subsection 3.4, we prove using a result of Farah [14] on approximate homomorphisms that $\pi_l^{-1} (1) \cap \prod S$ contains an element $g$ whose centralizer $C(g)$ is of large index. Then $S$ will contain elements from at least $|G : C(g)|^{\epsilon} |G|^{-\delta}$ cosets of $C(g)$, hence there are many $h \in \prod S$ with $\pi_l (h) = 1$, and $\prod S$ is much larger than $G_l$.

Finally, we mention that there is a useful result of Helfgott [18, Lemma 2.2] that allows us to bound $|S.S.S|$ in terms of larger iterated product-sets. He proves that if $S$ is a symmetric subset of an arbitrary group $G$ and $k \geq 3$ is an integer, then
\[
\frac{|\prod_k S|}{|S|} \leq \left( \frac{|S.S.S|}{|S|} \right)^{k-2}.
\]

3.3 The case of many small degrees

In this section we prove

**Proposition 16.** There are positive constants $\delta'$ and $Q$ depending only on $\epsilon$ and the constants in the assumptions, such that
\[
|\prod_{2m+1} S| > |S||G|^{-\epsilon} \prod_{i \in I_s} D_i^{\delta'},
\]
where $m$ is the same as in (A5).

The biggest issue here is that beside its size, we have no information about a set of form $\{ b | (a, b) \in \pi_{\leq i} (A) \}$. A large part of it might be contained in a coset of a proper subgroup and then (A4) does not apply with $\mu$ being the normalized counting measure on that set. To resolve this problem, we multiply sets of this form together with random elements of $G_i$. We need to construct a probability distribution supported on $S$ whose projection to most factors $G_i$ is well-behaved in the following sense.

**Lemma 17.** There is a subset $B \subset S$, and there is a partition of the indices $1, \ldots, n$ into two parts $J_g$ and $J_b$ such that
\[
\prod_{i \in J_g} |G_i| \leq |G|^{\delta/\delta'},
\]
where $\delta$ is related to the degrees of $G_i$.
and for any $i \in J_g$ and for any proper coset $gH \subset G_i$, we have

$$\chi_B(\{x \in G \mid \pi_i(x) \in gH\}) \leq |G_i|^{-\delta'},$$

where $\delta' > 0$ is a constant depending on $\varepsilon$ and on $L$.

**Proof.** We obtain the set $B$ by the following algorithm. First set $B = S$ and $J_g = \{1, \ldots, n\}$. Then iterate the following step as long as possible. If there is an index $i \in J_g$ and a coset $gH \subset G_i$ such that (16) fails, then replace $B$ by

$$\{x \in B \mid \pi_i(x) \in gH\}$$

and put $i$ into $J_b$. It is clear that (16) holds when this process terminates. As for (15), note that

$$\chi_S(B) \geq \prod_{i \in J_b} |G_i|^{-\delta'},$$

and $B$ is contained in a coset of a subgroup of index at least $\prod_{i \in J_b} |G_i|^{1/L}$ by (10). These together and the assumption of Proposition 14 on $S$ imply

$$\prod_{i \in J_b} |G_i|^{-\delta'} < \left( \prod_{i \in J_b} |G_i|^{1/L} \right)^{-\varepsilon} |G|^\delta,$$

and (15) follows easily if we set $\delta' = \varepsilon/2L$. \qed

Now assume that $i \in J_g$. Then, starting from arbitrary sets $A_1, \ldots, A_{2m} \subset G_i$ of the same size $|G_i|^\delta < D < |G_i|^{1-1/3L}$, we construct a measure $\lambda_m$ for which (A4) is applicable.

Choose the elements $x_j$ for $1 \leq j \leq 2m - 1$ independently at random according to the distribution $\chi_B$. Set $y_j = \pi_i(x_j)$. For $0 \leq k \leq m$ define

$$\lambda_k = \chi_{A_1} \ast 1_{y_1} \ast \chi_{A_2} \ast 1_{y_2} \ast \ldots \ast 1_{y_{2k-1}} \ast \chi_{A_{2k}},$$

where $1_y$ denotes the unit mass measure at $y$.

**Lemma 18.** If $i \in J_g$, then there is a constant $\delta'$ depending only on $\varepsilon$ and $L$ such that the probability of the event that

$$\lambda_k(gH) < D^{-\delta'/10^k}$$

holds for any proper coset $gH < G_i$, if $H \in H_l$ for some $l \leq k$ is at least

$$1 - (2^k - 1)|G_i|^{-\delta'}.$$

**Proof.** Let $\delta'$ be twice the $\delta'$ of the previous lemma. For $k = 0$, the claim follows from $L/D < D^{-\delta'}$ which is an inequality of form (12). We assume that $k > 0$ and that the claim holds for $k - 1$. Set

$$\eta_k = \chi_{A_{2k-1+1}} \ast 1_{y_{2k-1+1}} \ast \chi_{A_{2k-1+2}} \ast 1_{y_{2k-1+2}} \ast \ldots \ast 1_{y_{2k-1}} \ast \chi_{A_{2k}}$$
and assume that \( y_1, \ldots, y_{2^{k-2}}-1 \) and \( y_{2^{k-2}}-1, \ldots, y_{2^k-1} \) are chosen in such a way that \( \lambda_{k-1} \) and \( \eta_{k-1} \) satisfy
\[
\lambda_{k-1}(gH) < D^{-\delta'/10^k-1} \quad \text{and} \quad \eta_{k-1}(gH) < D^{-\delta'/10^k-1}
\]
for subgroups \( H \in \mathcal{H}_{k-1} \). By the induction hypothesis, the probability of such a choice is at least \( 1 - (2^k - 2)|G_1|^{-\delta'} \). Now assume that \( \lambda_k = \lambda_{k-1} * 1_{y_{2^k-1}} * \eta_{k-1} \) violates (17) for some \( g \in G \) and \( H \in \mathcal{H}_k \). To shorten the notation write \( y = y_{2^k-1} \). We prove that \( y \) is in a set of \( \pi_i(\chi_B) \) measure at most \( |G_i|^{-\delta'} \), and this set will depend only on \( \lambda_{k-1} \) and \( \eta_{k-1} \), in particular it will be independent of the choice of \( H \) and \( g \). Let \( \{h_j\} \) be a left transversal for \( H \) (i.e. a system of representatives for left \( H \)-cosets). Then it is easy to see that \( \{g h_j^{-1}\} \) is a right transversal for \( gHg^{-1} \), hence
\[
\lambda_k(gH) = \sum_j \lambda_{k-1}(gHg^{-1}g h_j^{-1}) \eta_{k-1}(y^{-1}h_j H)
\]
We claim that for some index \( j \), we have
\[
\lambda_{k-1}(B_j) \geq D^{-\delta'/10^k}_2 \quad \text{and} \quad \eta_{k-1}(C_j) \geq D^{-\delta'/10^k}_2,
\]
where \( B_j = gH h_j^{-1} \) and \( C_j = y^{-1}h_j H \). Assume to the contrary that this fails. Then we have
\[
\sum_j \lambda_{k-1}(B_j) \eta_{k-1}(C_j) = \sum_{j: \lambda_{k-1}(B_j) < D^{-\delta'/10^k}_2} \lambda_{k-1}(B_j) \eta_{k-1}(C_j)
+ \sum_{j: \eta_{k-1}(C_j) < D^{-\delta'/10^k}_2} \lambda_{k-1}(B_j) \eta_{k-1}(C_j)
\leq D^{-\delta'/10^k},
\]
a contradiction.

Let \( j \) be such that (19) holds. Define \( H_1 = h_j H h_j^{-1} \) and \( H_2 = y^{-1}H_1y \). Notice that \( B_j, B_j \subset H_1 \) and \( C_j, C_j \subset H_2 \). This shows that there are subgroups \( H_1, H_2 \in \mathcal{H}_k \) such that
\[
(\tilde{\lambda}_{k-1} * \lambda_{k-1})(H_1) \geq D^{-2\delta'/10^k}_4 \quad \text{and} \quad (\tilde{\eta}_{k-1} * \eta_{k-1})(H_2) \geq D^{-2\delta'/10^k}_4 \quad (20)
\]
and \( H_1 = y H_2 y^{-1} \). For fixed \( H_1 \) and \( H_2 \), this restricts \( y \) to a single \( N(H_2) \)-coset. By Lemma 17, this is a set of \( \chi_B \) measure at most \( |G_i|^{\delta/2} \). The final step is to show that the number of possible pairs \( H_1, H_2 \) such that (20) holds is at most \( |G_i|^{\delta/2} \).

Suppose that we have \( M \) distinct subgroups \( H_1 \in \mathcal{H}_k \) such that
\[
(\tilde{\lambda}_{k-1} * \lambda_{k-1})(H_1) \geq D^{-2\delta'/10^k}_4.
\]
If \( H_1 \) and \( H_1' \) are two such subgroups, then \( H_1 \cap H_1' \preceq L H^4 \) for some \( H^4 \in \mathcal{H}_{k-1} \). By the induction hypothesis, we have \( \tilde{\lambda}_{k-1} * \lambda_{k-1}(H^4) \leq D^{-\delta'/10^k-1} \), hence
\( \lambda_{k-1} * \lambda_{k-1}(H_1 \cap H_2) \leq LD^{-\delta'/10^k-1} \). By the inclusion-exclusion principle, we have
\[ MD^{-2\delta'/10^k}/4 - M^2LD^{-\delta'/10^k-1} \leq 1. \]
This is violated if \( M = D^{\delta'/4 \cdot 10^k-1} \), in fact we need \( D^{\delta'/2 \cdot 10^k} > 4(1+L) \), which is an inequality of form (12). Thus \( M < D^{\delta'/4 \cdot 10^k-1} \), and as the case of \( H_2 \) is similar, the proof is complete. \( \square \)

Using property (A4), we get the following simple

**Corollary 19.** Assume that \( |G_i|^{\delta} < D < |G_i|^{-1/3L} \), and let \( A' \subset G_i \) be any set of cardinality \( D \). There is a positive number \( \delta' \) depending only on \( \varepsilon \) and the constants in (A1)-(A5) such that for the above defined \( \lambda_m \), we have
\[ \| \lambda_m \ast \chi_{A'} \|_2 \ll D^{-1/2-\delta'} \]
with probability at least 1/2.

**Proof.** By Lemma 18 (and using (12)), we have with probability at least 1/2 that \( \lambda_m(gH) < LD^{-\delta'} \) with some \( \delta' > 0 \) for every proper coset \( gH \). By (12), we have \( L < D^{-\delta''/2} \). If say \( \| \lambda_m \|_2 > |G_i|^{-1/2+1/12L} \), then we get
\[ \| \lambda_m \ast \chi_{A'} \|_2 \leq \| \lambda_m \|_2^{1/2+\delta'} \| \chi_{A'} \|_2^{1/2} \]
by (A4) with \( \mu = \lambda_m \) and \( \nu = \chi_{A'} \). Otherwise the claim is trivial by Young’s inequality. \( \square \)

In what follows, we need some basic facts about entropy. Let \( \mu \) be a probability measure on \( G \), and let \( \mathcal{A} \) be a partition of \( G \). The entropy of \( \mathcal{A} \) is defined by
\[ H_\mu(\mathcal{A}) = \sum_{A \in \mathcal{A}} -\mu(A) \log(\mu(A)) \]
with the convention \( 0 \cdot \log 0 = 0 \). We also use the notation \( H_\mu \) for the entropy of the partition consisting of one element sets. The inequalities
\[ |\text{supp } \mu| \geq e^{H_\mu} \geq \frac{1}{\| \mu \|_2} \]
are well-known. If \( B \subset G \), we write \( \mu|_B(A) = \mu(A \cap B)/\mu(B) \), and if \( B \) is another partition, we define the conditional entropy by
\[ H_\mu(\mathcal{A}|\mathcal{B}) = \sum_{B \in \mathcal{B}} H_{\mu|_B}(\mathcal{A}) \mu(B). \]
It is easy to see that
\[ H_\mu(\mathcal{A} \vee \mathcal{B}) = H_\mu(\mathcal{A}|\mathcal{B}) + H_\mu(\mathcal{B}), \]
where \( \mathcal{A} \vee \mathcal{B} \) denotes the coarsest partition that is finer than both \( \mathcal{A} \) and \( \mathcal{B} \). On finite sets, partitions and \( \sigma \)-algebras are essentially the same, hence we make no distinction.

Finally, we turn to the
Proof of Proposition 16. First we introduce a couple of $\sigma$-algebras (partitions) on the set $A^{\times (2^m+1)}$, i.e. on the $2^m + 1$-fold Cartesian product of $A$. Let $A_i$ be the coarsest $\sigma$-algebra, for which the projection map
\[
\pi_i : A^{\times (2^m+1)} \to G^{\times (2^m+1)}
\]
is measurable. Furthermore, let $\mathcal{B}$ be the coarsest $\sigma$-algebra, for which the map
\[
(a_1, \ldots, a_{2^m}, a_{2^m+1}) \mapsto a_1 x_1 a_2 x_2 \cdots a_{2^m-1} a_{2^m} a_{2^m+1}
\]
is measurable, where the elements $x_1, \ldots, x_{2^m-1}$ are chosen independently at random according to the distribution $\chi_B$, hence the partition $\mathcal{B}$ is random.

Denote by $\mu$ the measure $\chi \otimes (2^m+1)$ on $A^{\times (2^m+1)}$. It follows from the definition that the entropy of the measure $\chi_A^* 1_{x_1} \cdots 1_{x_{2^m-1}}$ equals $H_{\mu}(B)$. We write for the expectation of $H_{\mu}(B)$:
\[
E[H_{\mu}(B)] \geq \sum_{i=1}^{n} E[H_{\mu}(B \wedge A_i | A_{i-1})] \\
\geq \sum_{i \in I_s \cap J_s} \left( \frac{\log D_i}{2} + \frac{(1 + 2\delta') \log D_i}{2} - \log c \right) + \sum_{i \in I_s \cap J_s} \log D_i \\
\geq \log |A| + \sum_{i \in I_s \cap J_s} \delta' \log D_i - n \log c.
\]
The second inequality follows from Corollary 19 and $c$ is the implied constant there. And $A \wedge B$ denotes the finest partition that is coarser than both $A$ and $B$. This implies in turn that for some choices of $x_1, \ldots, x_{2^m-1}$, we have
\[
|A \cdot x_1 \cdot A \cdot x_2 \cdots x_{2^m-1} \cdot A| \geq c^{-n} |A| |G|^{-\delta} \prod_{i \in I_s} D_i^\delta',
\]
where we also used (15). Note that we can assume $c^n < |G|^\delta$ by (12), and recall that $|A| > |S||G|^{-2\delta}$ by (13), hence Proposition 16 follows.

3.4 The case of many large degrees

This section is devoted to the proof of

Proposition 20. There is a positive constant $\delta'$ depending only on $\epsilon$ and $L$, such that
\[
|\prod_{I_s} S| \geq |G|^{\delta' - \delta} \prod_{i \in I_t} D_i
\]
Recall that $G_s = \times_{i \in I} G_i$, $G_l = \times_{i \in I} G_i$ and $\pi_s$ and $\pi_l$ are the projections to these subgroups respectively.

By (A3), any nontrivial representation of $G_i$ is of dimension at least $|G_i|^{1/L}$. It was pointed out by Nikolov and Pyber [24, Corollary 1] that a result of Gowers [17, Theorem 3.3] imply that if $A,B,C \subset G_i$ are subsets such that $|A||B||C| > |G_i|^{3-1/L}$ then $A.B.C = G_i$.

Let $i_1 \leq \ldots \leq i_{n''}$ be the indices in $I_l$ and for $1 \leq n'' \leq n'$ set $G_{\{i_1,\ldots,i_{n''}\}} = G_{i_1} \times \ldots \times G_{i_{n''}}$ and denote by $\pi_{\{i_1,\ldots,i_{n''}\}}$ the projection to this subgroup. We prove by induction that

$$\pi_{\{i_1,\ldots,i_{n''}\}}(A.A.A) = G_{\{i_1,\ldots,i_{n''}\}}.$$

For $n'' = 1$, this follows directly from [24, Corollary 1] and from $\pi_{i_1}(A) \geq D_{i_1} \geq |G_{i_1}|^{1-1/3L}$. Now assume that the claim holds for some $n''$ and take an arbitrary element $g \in G_{\{i_1,\ldots,i_{n''+1}\}}$. By the induction hypothesis there are elements $h_1,h_2,h_3 \in A$ such that

$$\pi_{\{i_1,\ldots,i_{n''}\}}(h_1h_2h_3) = \pi_{\{i_1,\ldots,i_{n''}\}}(g).$$

Define the sets

$$B_i = \{ x \in A \mid \pi_{\{i_1,\ldots,i_{n''}\}}(x) = \pi_{\{i_1,\ldots,i_{n''}\}}(h_i) \}$$

and note that

$$\pi_{i_{n''+1}}(B_i) \supset \pi_{i_{n''+1}}((\{ x \in A \mid \pi_{\leq i_{n''+1}}(x) = \pi_{\leq i_{n''+1}}(h_i) \}))$$

hence $|\pi_{i_{n''+1}}(B_i)| \geq D_{i_{n''+1}} \geq |G_{i_{n''+1}}|^{1-1/3L}$. Now an application of [24, Corollary 1] to the sets $\pi_{i_{n''+1}}(B_i)$ gives that $g \in \pi_{\{i_1,\ldots,i_{n''+1}\}}(A.A.A)$ whence the claim follows.

Define the distance of two elements $g,h \in G_s$ by

$$d(g,h) = \sum_{i \in I : \pi_s(g) \neq \pi_s(h)} \log |G_i|.$$

**Lemma 21.** If $|S.S.S| \leq |G|^{1-\varepsilon + \delta}$ then there is an element $g \in \prod_3 S$ such that

$$\pi_l(g) = 1 \quad \text{and} \quad d(\pi_s(g),1) > \delta' \log |G|,$$

where $\delta' > 0$ is a constant depending only on $\varepsilon$ and $L$.

Following Farah [14], we say that a map $\psi : G_l \to G_s$ is a $\delta'$–approximate homomorphism if

$$d(\psi(g)\psi(h),\psi(gh)) \leq \delta' \quad \text{and} \quad d(\psi(g),\psi(g^{-1}))^{-1} \leq \delta'$$

for all $g,h \in G_l$. Note that in [14], such a $\psi$ is called an approximate homomorphism of type II. We recall a result of Farah [14, Theorem 2.1] that will be
crucial in the proof. Let \( \psi : G_1 \to G_s \) be a \( \delta' \)–approximate homomorphism. Then there is a homomorphism \( \varphi : G_1 \to G_s \) such that

\[
d(\psi(g), \varphi(g)) \leq 24\delta'
\]

for all \( g \in G_1 \).

**Proof of Lemma 21.** Assume to the contrary that for any \( g \in \prod_{i} S \) with \( \pi_i(g) = 1 \), we have \( d(\pi_s(g), 1) \leq \delta \log |G| \). For each \( g \in G_1 \), pick an element \( h \in S.S.S \) with \( \pi_i(h) = g \) and set \( \psi(g) = \pi_s(h) \). This gives rise to a map \( \psi : G_1 \to G_s \), which of course depends on our choices for \( h \). It follows in turn that for any \( g \in G_1 \) and \( h \in S.S.S \) with \( \pi_i(h) = g \), we have \( d(\pi_s(h), \psi(g)) < \delta \log |G| \) and that \( \psi \) is a \( \delta' \)–approximate homomorphism. By [14, Theorem 2.1], there is a homomorphism \( \varphi \) with \( d(\psi(g), \varphi(g)) \leq 24\delta' \log |G| \) for any \( g \in G_1 \). The elements \( g \in G \) satisfying

\[
\pi_s(g) = \varphi(\pi_i(g))
\]

constitutes a subgroup \( H < G \) of index \( |G_s| \), since the cosets of \( H \) are represented by the elements \( g \) with \( \pi_i(g) = 1 \). For \( h_1 \in S.S.S \), the coset \( h_1H \) is represented by the element \( g_1 \) with \( \pi_i(g_1) = 1 \) and \( \pi_s(g_1) = \pi_s(h_1)\varphi(\pi_i(h_1))^{-1} \).

Since

\[
d(\pi_s(h_1), \varphi(\pi_i(h_1))) \leq d(\pi_s(h_1), \psi(\pi_i(h_1))) + d(\psi(\pi_i(h_1)), \varphi(\pi_i(h_1)))
\]

\[
< 25\delta' \log |G|,
\]

there is an index set \( I \subset I_s \) with \( |I| < |G|^{25\delta'} \) such that \( \pi_i(g_1) \neq 1 \) exactly if \( i \in I \). If \( I \) is given there are at most \( |G|^{25\delta'} \) choices for \( g_1 \). Thus \( S.S.S \) is contained in \( 2^n|G|^{25\delta'} \) \( < |G|^{26\delta'} \) cosets of \( H \). This is a contradiction if

\[
|G_s|^{-\varepsilon}|G|^{26\delta'+\delta} < 1.
\]

Since \( |G_i| \leq |S.S.S| \leq |G|^{1-\varepsilon+\delta} \), we have \( |G_s| \geq |G|^{\varepsilon-\delta} \). Now, if \( \delta \) is small enough (e.g. \( \delta < \varepsilon^2/10 \)) we can get the desired contradiction by an appropriate choice of \( \delta' \). \( \square \)

**Proof of Proposition 20.** First we calculate the index of the centralizer \( C(g) \) of \( g \), the element constructed in Lemma 21. An element \( h \) commutes with \( g \) if and only if \( \pi_i(h) \in C(\pi_i(g)) \) for all indices \( i \) for which \( \pi_i(g) \neq 1 \). For such an \( i \), \( |g : C(\pi_i(g))| > |G_i|^{1/L} \). Recall that we assume that all the \( G_i \) are simple, in particular their centers are trivial. Now we see that \( |g : C(g)| \sim |G|^{\delta'/L} \) with the \( \delta' \) of Lemma 21. Then \( S \) contains elements from at least \( |G|^{\delta'/L-\delta} \) cosets of \( C(g) \). Thus the set

\[
\{ sas^{-1} | s \in S \} \subset \prod_{11} S
\]

contains at least \( |G|^{\delta'/L-\delta} \) different elements \( h \) with \( \pi_i(h) = 1 \), whence

\[
|\prod_{12} S| \geq |G|^{\delta'/L-\delta} \prod_{s \in I_1} D_s,
\]

which was to be proven. \( \square \)
We conclude with the

Proof of Proposition 14. By Propositions 16 and 20, we have

$$|\prod_{2^{m+1}} S| > |S||G|^{-Q\delta} \prod_{i \in I} D_i^{\delta_i}$$

and

$$|\prod_{12} S| > |G|^{\delta_2^i - \delta} \prod_{i \in I} D_i.$$

with some constants $\delta_1, \delta_2$ and $Q$. Multiply the first inequality with the $\delta_1$th power of the second one, and use $|G| \geq |S|$ and $\prod D_i = |A| \geq |S| |G|^{-\delta}$ to get

$$|\prod_{2^{m+1}} S| |\prod_{12} S|^{\delta_1} > |S|^{1+\delta_1 + \delta_2^i} |G|^{-Q\delta}.$$

By the hypothesis on the set $S$ for $H = \{ 1 \}$, we get $|S| > |G|^{1-\delta}$. Therefore (14) gives the claim if $\delta$ is sufficiently small. 

\[ \square \]

4 (A1)–(A5) for $G_i = SL_d(F_{p^k})$

Let $K$ be a number-field and let $I \subset O_K$ be a square-free ideal. Then $I = P_1 \cdots P_n$ for some prime ideals, and $G = SL_d(O_K/I) = SL_d(O_K/P_1) \times \cdots \times SL_d(O_K/P_n)$. The last ingredient we need for the proof of Theorem 1 is that the groups $G_i = SL_d(O_K/P_i)$ satisfy the assumptions (A1)–(A5). We write $F_{p^k}$ for the finite field of order $p^k$.

(A1) is immediate, and (A2) is a classical result of Jordan. Regarding (A3), Harris an Hering [20] proved that any nontrivial representation of $SL_d(F_q)$ is of dimension at least $q^d - 1 = 1$ or $(q - 1)/2$ when $d = 2$ and $q$ is odd. In fact for our purposes it is enough to note that any such representation restricted to an appropriate subgroup isomorphic to $SL_2(F_p)$ gives rise to a nontrivial representation, which is of dimension at least $(p-1)/2$ by a classical result of Frobenius [15].

We study (A4) and (A5) in the next two sections.

4.1 Assumption (A4)

We recall some results of Helfgott. Let $G = SL_d(F_p)$, and let $S \subset G$ be a set which is not contained in any proper subgroup. Suppose further that $|S| < |G|^{1-\varepsilon}$ for some $\varepsilon > 0$. Then if $d = 2$ [18, Key Proposition] or if $d = 3$ [19, Main Theorem], there is a $\delta > 0$ depending only on $\varepsilon$ such that $|S.S.S| \gg |S|^{1+\delta}$. These results imply (A4) for $G_i = SL_d(F_{p^k})$ if $d = 2$ or $d = 3$ the same way as we proved Theorem 3 using Proposition 14. We show below that the argument in [18] extends easily for groups $G = SL_d(F_{p^k})$. After the circulation of an early version of this paper I have learnt that this extension of Helfgott’s theorem was recently proven by Oren Dinai in his PhD thesis [12].

Let $\Lambda$ be a subset of the multiplicative group $F_{p^k}^\times$. Denote by $\Lambda^r$ the set of $r$th powers of the elements of $\Lambda$ and set

$$w(\Lambda) = \{ w(a) \mid a \in \Lambda \}, \quad \text{where} \quad w(a) = a + a^{-1}.$$
The only notable change needed to extend Helfgott’s argument for the case $k > 1$ is to replace [18, Proposition 3.3] by the following

**Proposition 22.** Let $\Lambda \subset \mathbb{F}_p^\times$ be a set which contains 1 and is closed under taking multiplicative inverses. Let $a_1, a_2 \in \mathbb{F}_p^\times$, and assume that if $w(\Lambda^2)$ is contained in a proper subfield $F$ of $\mathbb{F}_p^\times$, then $a_1/a_2 \notin F$. Now if $|\Lambda| < p^{(1-\delta)k}$, then
\[ |\{a_1 w(bc) + a_2 w(bc^{-1}) \mid b, c \in \prod_4 \Lambda\} | \gg |\Lambda|^{1+\varepsilon} \]
with a constant $\varepsilon$ depending only on $\delta$.

The proof follows the same lines as that of [18, Proposition 3.3].

**Proof.** Set $\Lambda_1 = \Lambda^2 \Lambda^2$. Using the substitution $b = \bar{b} \bar{c}$ and $c = \bar{b} \bar{c}^{-1}$, we see that
\[
\begin{align*}
\{a_1 w(\Lambda_1) + a_2 w(\Lambda_1) & = \{a_1 w(\bar{b}^2) + a_2 w(\bar{c}^2) \mid b, c \in \Lambda \Lambda \} \\
& \subset \{a_1 w(bc) + a_2 w(bc^{-1}) \mid b, c \in \prod_4 \Lambda \}.
\end{align*}
\]
If $w(\Lambda^2)$ is contained in a subfield $F$, then $a_1/a_2 \notin F$ by assumption, and then trivially
\[ |a_1 w(\Lambda_1) + a_2 w(\Lambda_1)| \geq |w(\Lambda^2)|^2 \geq \frac{1}{16} |\Lambda|^2, \]
and the claim follows.

Therefore we will assume now that $w(\Lambda^2)$ generates $\mathbb{F}_p^\times$. Assume that
\[ |a_1/a_2 w(\Lambda_1) + w(\Lambda_1)| \leq K|\Lambda| \]
for some constant $K$. By the Ruzsa-Plünnecke inequalities [27] (see also [31, Corollary 6.9])
\[ |w(\Lambda_1) + w(\Lambda_1) - w(\Lambda_1) - w(\Lambda_1)| \ll K^4|\Lambda|. \]
Note that $w(a)w(b) = w(ab) + w(ab^{-1})$, hence
\[ w(\Lambda^2)w(\Lambda^2) \subset w(\Lambda_1) + w(\Lambda_1) \]
and
\[ |w(\Lambda^2)w(\Lambda^2) - w(\Lambda^2)w(\Lambda^2)| \ll K^4|\Lambda|. \]
This would contradict the sum-product theorem if $K = |\Lambda|^\varepsilon$ with $\varepsilon$ small enough. The most convenient reference for us is [30, Theorem 1.5] that we can apply with $A = w(\Lambda^2)$ and $a = w(1) = 2$. However the contradiction could also be deduced from the results of [10] or [9].

To use this proposition we need to replace [18, Corollary 4.5] by

**Lemma 23.** Let $S \subset SL_2(\mathbb{F}_p^\times)$ be symmetric containing 1, and assume that it is not contained in any proper subgroup. Let $F$ be a proper subfield of $\mathbb{F}_p^\times$. Then there is an absolute constant $R$ such that there is a matrix
\[ x = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \prod_R S \]
with $abcd \neq 0$ and $ad/bc \notin F$. 29
Proof. In this proof the value of $R$ may be different at different occurrences. First note that for any matrix $x$ with entries as above, $ad + bc = 1 \in F$ and hence

$$bc = \frac{1}{ad/bc - 1},$$

so $x$ satisfy the requirements of the lemma exactly if $bc \notin F$. If $x$ does not satisfy this, look at $x^2$ and notice that the product of the off-diagonal entries is $bc(Tr(x))^2$, hence it remains to show that $\prod_{\alpha} S$ contains an element with nonzero off-diagonals and with $(Tr(x))^2 \notin F$.

Note that if span$(\prod_i S) = \text{span}(\prod_{i+1} S)$, where span$(X)$ denotes $F_{p^k}$-linear span in $\text{Mat}_2(F_{p^k})$, then span$(\prod_m S) = \text{span}(\prod_i S)$ for any $m > l$. From this we conclude that as $S$ is not contained in a proper subgroup, $\prod_4 S$ must span $\text{Mat}_2(F_{p^k})$. Let $y_1, y_2, y_3, y_4 \in \prod_i S$ be a basis of $\text{Mat}_2(F_{p^k})$ and let $z_1, z_2, z_3, z_4$ be the dual basis with respect to the non-degenerate form $Tr(yz)$. Denote by $\omega$ an element of $F_{p^k}$ which is not in $F$ but $\omega^2 \in F$. If there is no such element, the rest of the proof is even simpler. Consider the $16 F$–vectorspaces

$$\omega^{\alpha_1} F \cdot z_1 + \omega^{\alpha_2} F \cdot z_2 + \omega^{\alpha_3} F \cdot z_1 + \omega^{\alpha_4} F \cdot z_1,$$

where the $\alpha_i$ takes the values 0 and 1 independently. Now we invoke Lemma 4.4 from Helfgott [18], which gives that there is a matrix $\bar{x} \in \prod_R S$ which is not contained in any of the above subspaces if $R$ is large enough. By definition, there is an index $i$ such that $(Tr(y_i \bar{x}))^2 \notin F$. It may happen that one or both off-diagonal entries are zero. Using [18, Lemma 4.4] now for the representation of $SL_2(F_{p^k})$ acting on $\text{Mat}_2(F_{p^k})$ by conjugations, we see that $wy_i \bar{x}w^{-1}$ has no zero entries for some $w \in \prod_R S$. This proves the claim. □

We remark, that in the way [18, Lemma 4.4] is stated, it gives an $R$ which depends on the dimension of $\text{Mat}_2(F_{p^k})$ over $F$, however it is easily seen by a careful analysis of the proof in [18] that the dependence is only on the dimension of the subspaces we want to avoid.

Extending [18, Key Proposition] to arbitrary finite fields. The proof on pp. 616 [18] is given for arbitrary finite fields up to the point when the set $V$ is constructed, except that we get $|V| < p^{k(1-\delta/3)}$ not $|V| < p^{1-\delta/3}$. If $w(V)$ is contained in a proper subfield of $F_{p^k}$ then denote this subfield by $F$, and instead [18, Corollary 4.5] use Lemma 23 to construct the matrix

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

In what follows simply use Proposition 22 instead of [18, Proposition 3.3]. □

4.2 Assumption (A5)

We prove that $SL_d(F_{p^k})$ satisfies (A5) with $L$ depending on $d$ and $k$. Note that we can embed $SL_d(F_{p^k})$ into $GL_{kd}(F_p)$ by Weil restriction. We again rely
on the description of the subgroup structure of $GL_d(F_p)$ given by Nori [25].
Recall that for a group $H < GL_d(F_p)$, $H^+$ denotes the subgroup generated by
elements of order $p$. By [25, Theorem B] there is a connected algebraic subgroup
$\bar{H} < GL_d$ such that $\bar{H}(F_p)^+ = H^+$. By [25, Theorem C] there is a commutative
$F < H$ such that $p \nmid |F|$ and $H \leq_{L_1} FH$ with a constant $L_1$ depending only on
$d$. Moreover, it follows from the proof there, that if $P$ is any $p$–Sylow subgroup
of $H^+$, then $F$ can be chosen to satisfy

$$F < \mathcal{N}_H(P), \quad F \cap P = \emptyset \quad \text{and} \quad [\mathcal{N}_H(P) : FP] < L_1.$$  \hspace{1cm} (22)

The choice of $F$ is not unique, even for a fixed Sylow subgroup $P$, however the
following is true. Let $K < \mathcal{N}_H(P)/P$ be a group whose order is prime to
$P$. Then there is an $F < \mathcal{N}_H(P)$ with $K = FP/P$ by [26, Theorem 7.41] and all
such subgroups $F$ are conjugates of each other by elements of $P$, see Rotman
[26, Theorem 7.42].

**Proposition 24.** Let $G$ be a quasi-simple subgroup of $GL_d(F_p)$ such that $G =
G^+$. There are classes $\mathcal{H}_0, \ldots, \mathcal{H}_m$ of subgroups of $G$ such that the following
hold with some constants $L, m$ depending only on $d$:

(i) $\mathcal{H}_0 = \{Z(G)\}$,

(ii) each $\mathcal{H}_i$ is closed under conjugation by elements of $G$.

(iii) for every proper subgroup $H < G$ there is some $i$ and a subgroup $H^i \in \mathcal{H}_i$ such that $H \leq_{L} H^i$,

(iv) for every pair of subgroups $H_1, H_2 \in \mathcal{H}_i, \quad H_1 \neq H_2$ there is some $i' < i$ and $H^i \in \mathcal{H}_{i'}$ such that $H_1 \cap H_2 \leq_{L} H^i$.

**Proof.** In each subgroup $H < G$ which is generated by elements of order $p$, distinguish a
$p$-Sylow subgroup $P$. This can be arbitrary, but should be fixed throughout the proof. For integers $i$ and $j$ we define the classes $\mathcal{H}_{i,j}$. A subgroup $H < G$ belongs to $\mathcal{H}_{i,j}$ precisely if $Z(G) < H$, $\dim H = i$ and $j$ is the least integer for which the following hold. There is a commutative subgroup $F < \mathcal{N}_H(P)$ such that

$$Z(G) < F, \quad H = FH^+, \quad F \cap P = \emptyset \quad \text{and} \quad [\mathcal{N}_{H^+}(P) : (F \cap H^+)] < L_1^{d-i},$$  \hspace{1cm} (23)

and there is a $j$ dimensional subspace $V$ of $Mat_d(F_p)$ such that

$$F = V \cap \mathcal{N}_G(P) \cap \mathcal{N}_G(H^+).$$  \hspace{1cm} (24)

Order the nonempty classes $\mathcal{H}_{i,j}$ in such a way that $\mathcal{H}_{i,j}$ precedes $\mathcal{H}_{i',j'}$ if $i < i'$ or $i = i'$ and $j < j'$.

The first nonempty class is $\mathcal{H}_{0,j} = \{Z(G)\}$ for some $j$, and (i) follows. Since
conjugation is a linear transformation on $Mat_d(F_p)$, (ii) is clear.
Let \( H < G \) be a proper subgroup, and replace it by \( Z(G)H \) if necessary, to ensure that \( Z(G) < H \). Let \( F \) be a subgroup of \( N_H(P) \) that satisfies (22).

Without loss of generality, we can assume that \( Z(G) < F \). Set

\[
F^\sharp = \text{span}(F) \cap N_G(P) \cap N_G(H^+),
\]

where \( \text{span}(F) \) is the linear span of \( F \) in the vectorspace \( \text{Mat}_d(F_p) \). First we remark that \( F^\sharp \) does not contain an element of order \( p \), in fact its elements can be mutually diagonalized over an appropriate extension field. This implies that \( F^\sharp \cap P = \emptyset \).

Since \( F^\sharp \subset N_G(H^+) \), we can define the subgroup \( H^\sharp = F^\sharp H^+ \), and we have \( (H^\sharp)^+ = H^+ \).

By \([21, \text{Claim } 11.19]\), it is enough to prove that

\[
\text{dim}(\text{span}(F)) \leq 1 \quad \text{for } i = \dim \tilde{H} \quad \text{and with some } j \leq \text{dim} \text{(span}(F)), \quad \text{since } F^\sharp \text{ is commutative, and we have}
\]

\[
[N_H(\pi) : (F^\sharp \cap H^+)P] \leq [N_H(\pi) : (F \cap H^+)P] = [N_{FH}(\pi) : FP] \leq L_1.
\]

Here the equation in the middle follows from the fact \( N_{FH}(\pi) = FN_H(\pi) \).

It remains to show (iv). Let \( H_1 \) and \( H_2 \) be two different groups in \( H_{i,j} \). If \( \tilde{H}_1 \neq \tilde{H}_2 \), then

\[
\text{dim}(\tilde{H}_1 \cap \tilde{H}_2) \leq \text{dim} \tilde{H}_1 \cap \tilde{H}_2 < i
\]

and \( (H_1 \cap H_2)^\sharp \in H_{i',j'} \) with some \( i' < i \). Therefore we may assume \( \tilde{H}_1 = \tilde{H}_2 \) and hence \( H_i^\sharp = H_j^\sharp \).

Let \( P \) be the distinguished \( p \)-Sylow subgroup and denote by \( F_i < N_H(P) \) and \( V_i \) (\( i = 1, 2 \)) the subgroups and subspaces for which (23) and (24) hold. We show that there is an \( H \in H_{i,j} \) for some \( j' < j \) such that \( H_1 \cap H_2 \leq L_1^{2d-j+1} \).

We have \( [N_H(\pi) : F_i P] < L_1^{2d-j} \) for \( l = 1, 2 \), hence

\[
[N_{H_1 \cap H_2}(\pi) : F_1 P \cap F_2 P] < L_1^{2d-j+1}.
\]

By [26, Theorem 7.41] as mentioned before, there is a subgroup \( F < N_H(P) \) with \( F \cap P = \emptyset \) and \( FP = F_1 P \cap F_2 P \). Moreover, since conjugation is linear we can assume by [26, Theorem 7.42] that \( F = F_1 \cap F_2 \). The claim follows if we define \( H = FH^+ \), since

\[
[N_H(\pi) : (F \cap H^+)P] \leq [N_{FH}(\pi) : F_1 P \cap F_2 P] \cdot [N_H(\pi) : (F_2 \cap H^+)P]
\]

and \( \text{dim}(V_1 \cap V_2) < j \).

\[\square\]

5 Proof of Theorem 1

Let notation be the same as in the statement of the theorem. First we note that by [21, Claim 11.19], it is enough to prove that \( G(SL_d(\mathcal{O}_K/I), \pi_t(S')) \) form a family of expanders with some \( S' \subset \Gamma \), hence we can assume without loss of generality that Theorem 2 holds with \( S = S' \). If \( H < SL_d(\mathcal{O}_K/I) \) and \( \pi_t(S) \subset H \), then by Theorem 2, \( [SL_d(\mathcal{O}_K/I) : H] < C \) for some constant
Let $J$ be a square-free ideal for whose prime factors $P$, $\pi_P(S)$ does not generate $SL_d(\mathcal{O}_K/P)$. Since each proper subgroup in $SL_d(\mathcal{O}_K/P)$ is of index at least $N(P)^{\delta'}$ for some $\delta' > 0$, we get $N(J) < C^{\delta'}$. Here, and everywhere below $\delta'$ is a constant which may depend on $S$ and which need not be the same at different occurrences. Thus there is at most a finite number of prime ideals $P$ such that $\pi_P(S)$ is not generating, and from now on, we denote by $J$ the product of those prime ideals.

Let $I$ be an ideal which is prime to $J$ and write $G = SL_d(\mathcal{O}_K/I)$, and $\mathcal{S} = \pi_I(S)$. Denote by $l^2(G)$ the vectorspace of complex valued functions on $G$. Consider the operator on $l^2(G)$ which is convolution by $\chi_S$ from the left. Denote its matrix in the standard basis by $M$. It is plain that $|\mathcal{S}| M$ is the adjacency matrix of the graph $G(G, \mathcal{S})$. In light of the results of Dodziuk [13], Alon and Milman [3] and Alon [2] already mentioned in the introduction, we have to give an upper bound on the second largest eigenvalue of $M$ independently of $I$. For $g \in G$, denote by $\alpha(g)$ the left translation by $g$ on $l^2(G)$. $\alpha$ is called the regular representation of $G$, and it is well known that $l^2(G)$ decomposes as a direct sum $V_0 \oplus V_1 \oplus \ldots \oplus V_m$, such that each $\alpha_{V_i}$ is irreducible and the multiplicity of every irreducible representation of $G$ in this decomposition is the same as its dimension. Therefore it is left to show that if $\beta$ is a nontrivial irreducible representation of $G$, and $\lambda$ is an eigenvalue of the operator

$$\frac{1}{|\mathcal{S}|} \sum_{g \in \mathcal{S}} \beta(s),$$

then $\lambda < c < 1$ for some constant $c$ independent of $I$. Replacing $I$ by a larger ideal if necessary, we may assume that the representation is faithful. Faithful representations of $G$ are tensor products of nontrivial representations of the direct factors, hence they are of dimension at least $|G|^{\delta'}$ as we noted at the beginning of section 4. Hence $\lambda$ is an eigenvalue of $M$ with multiplicity at least $|G|^{\delta'}$.

Denote by $(M)_{i,j}$ the $i,j$ entry of $M$ and notice that for an integer $k$, the rows of $M^k$ are translates of $\lambda_{\mathcal{S}}^{(k)}$. Then

$$\text{Tr}(M^{2k}) = \sum_{i,j \leq |G|} (M^k)_{i,j}^2 = |G| ||\lambda_{\mathcal{S}}^{(k)}||^2_2,$$

whence

$$\lambda^{2k} \leq |G|^{1-\delta'} ||\lambda_{\mathcal{S}}^{(k)}||^2_2. \quad (25)$$

If the index of a subgroup $H < SL_d(\mathcal{O}_K/I)$ is large, then we can cancel the implied constant in Theorem 2 by making $\delta$ smaller. If the index is small, then we can get a nontrivial bound $\lambda_{\mathcal{S}}^{(k)}(H) < c < 1$, since we assumed that $\mathcal{S}$ generates the group. Thus if $I$ is restricted to ideals prime to $J$, Theorem 2 holds with the implied constant set to 1. Now apply it for $H = \{1\}$ to get

$$||\lambda_{\mathcal{S}}^{(\log_2 N(I))}||^2_2 < |G|^{-\delta'}.$$
We saw in section 4 that $G$ satisfies (A0)–(A3) and (A5). It also satisfy (A4) if $d = 2$ or if $d = 3$ and $K = \mathbb{Q}$ or if we assume that (1) holds if $F$ ranges over the fields $\mathcal{O}_K/P$, $P$ prime. Therefore we can apply Theorem 3 repeatedly to get

$$\|\chi^{(C\log(N/I))}\|_2 < |G|^{-1+\varepsilon}$$

for arbitrary $\varepsilon > 0$ with some constant $C$ depending on $\varepsilon$. If $\varepsilon$ is less than the $\delta'$ in (25), the theorem follows.
