Abstract

Gamma-ray bursts are most luminous explosions in the universe. Their ejecta are believed to move towards Earth with a relativistic speed. The interaction between this “relativistic jet” and a circumburst medium drives a pair of (forward and reverse) shocks. The electrons accelerated in these shocks radiate synchrotron emission to power the broad-band afterglow of GRBs. The external shock theory is an elegant theory, since it invokes a limit number of model parameters, and has well predicted spectral and temporal properties.

On the other hand, depending on many factors (e.g. the energy content, ambient density profile, collimation of the ejecta, forward vs. reverse shock dynamics, and synchrotron spectral regimes), there is a wide variety of the models. These models have distinct predictions on the afterglow decaying indices, the spectral indices, and the relations between them (the so-called “closure relations”), which have been widely used to interpret the rich multi-wavelength afterglow observations. This review article provides a complete reference of all the analytical synchrotron external shock afterglow models by deriving the temporal and spectral indices of all the models in all spectral
regimes, including some regimes that have not been published before. The review article is designated to serve as a useful tool for afterglow observers to quickly identify relevant models to interpret their data. The limitations of the analytical models are reviewed, with a list of situations summarized when numerical treatments are needed.

**Keywords:** gamma ray bursts: general - radiation mechanisms: non-thermal

1. Introduction

Gamma-ray bursts (GRBs) are the most luminous explosions in the universe, which signify catastrophic events involving core collapses of some rapidly spinning massive stars and mergers of two compact objects (two neutron stars or one neutron star and one stellar-mass black hole). These events power an energetic, relativistic jet, which beams towards Earth and gives rise to Doppler-boosted powerful emission in $\gamma$-rays.

Although the nature of the progenitor and central engine as well as the detailed physics of $\gamma$-ray emission are still rather uncertain (for reviews, see e.g. Zhang and Mészáros, 2004; Piran, 2005; Mészáros, 2006; Zhang, 2007; Kumar and Zhang, 2013), a generic synchrotron external shock model has been well established to interpret the prompt emission and the broad-band afterglow data (Rees and Mészáros, 1992, 1994; Mészáros and Rees, 1993, 1997; Sari et al., 1998; Chevalier and Li, 2000). This model delineates the interaction between the relativistic GRB jet and a circumburst medium. During the initial interaction, a pair of shocks (forward and reverse) propagate into the ambient medium and the ejecta, respectively. After the reverse shock crosses the shell, the blastwave enters a self-similar phase described by the Blandford-McKee self-similar solution (Blandford and McKee, 1976). In this phase, the dynamics of the blastwave is solely determined by a few parameters (e.g. the total energy of the system, the ambient density and its profile).

Electrons are accelerated in both forward and reverse shocks, which radiate synchrotron emission in the magnetic fields behind the shocks that are believed to be generated in situ due to plasma instabilities (e.g. Medvedev and Loeb, 1999). Introducing several notations to parameterize micro-scopic processes, i.e. the fractions of shock energy that go to electrons and magnetic fields ($\epsilon_e$ and $\epsilon_B$), and the electron spectral index $p$, one can then calculate the instan-
taneous synchrotron spectrum at a given epoch, as well as the flux evolution with time (the lightcurve) for a given observed frequency.

Since the simplest external shock theory does not invoke details of a burst, and invokes only a limit number of model parameters, it is an elegant theory with falsifiable predictions. It turned out that the predicted power-law decay of lightcurves and broken power law instantaneous spectra are well consistent with many late time afterglow data in the pre-Swift era (e.g. Wijers et al., 1997; Waxman, 1997b; Wijers and Galama, 1999; Huang et al., 1999, 2000; Panaitescu and Kumar, 2001, 2002; Yost et al., 2003), suggesting that most of the observed multi-wavelength afterglows indeed originate from jet-medium interaction, and that synchrotron radiation is indeed the right radiation mechanism to power the observed emission. Later observations showed more complicated afterglow behaviors (e.g. Akerlof et al., 1999; Harrison et al., 1999; Berger et al., 2003; Fox et al., 2003; Li et al., 2003), which demand more complicated models (Mészáros et al., 1998) that invoke joint forward shock and reverse shock emission (Mészáros and Rees, 1997; Mészáros and Rees, 1999; Sari and Piran, 1999a,b; Kobayashi and Zhang, 2003b; Zhang et al., 2003), non-uniform density medium (Dai and Lu, 1998b; Chevalier and Li, 1999, 2000), continuous energy injection into the blastwave (Dai and Lu, 1998a; Rees and Mészáros, 1998; Zhang and Mészáros, 2001a), collimation of the jet (Rhoads, 1999; Sari et al., 1999; Zhang and Mészáros, 2002a; Rossi et al., 2002), hard electron injection spectrum (Dai and Cheng, 2001), etc. Nonetheless, these more complicated models, by introducing one or more additional assumptions/parameters, still have clear testable predictions regarding the afterglow decaying index $\alpha$, the spectral index $\beta$, and the relation between them (the so-called “closure relations”) (e.g. Zhang and Mészáros, 2004; Zhang et al., 2006, for a collection of these models). The Swift mission (Gehrels et al., 2004) made it possible to systematically detect the early phase of the GRB X-ray afterglow, which shows some un-predicted features (Tagliaferri et al., 2003; Burrows et al., 2005; Nousek et al., 2006; O’Brien et al., 2006; Evans et al., 2009) that demand multiple physical processes that shape the observed lightcurves (Zhang et al., 2006). Systematic data analyses (Zhang et al., 2007; Liang et al., 2007, 2008, 2009; Butler and Kocevski, 2007; Kocevski et al., 2007; Chincarini et al., 2007, 2010; Margutti et al., 2010) suggest that the X-ray afterglow is a superposition of the conventional external shock component and a radiation component that is related to the late central engine activity (e.g. Zhang, 2007, 2011; Zou et al., 2013). Nonetheless, the data indicate that the low-energy (optical and radio) afterglows (Kann et al., 2010, 2011; Chandra and Frail,
Recent Fermi observations suggest that the GeV afterglow after the prompt emission phase is also dominated by the emission from the external shock (Kumar and Barniol Duran, 2009; 2010; Ghisellini et al., 2010; He et al., 2011; Liu and Wang, 2011; Maxham et al., 2011). Observations with EVLA and ALMA start to reveal the early phase of GRB afterglow in the radio and sub-mm regime, during which reverse shock and self-absorption effects are important. These are the regimes not fully covered by the already published materials. With new data flooding in, it is essential to systematically survey a complete list of external shock models in all possible temporal and spectral regimes.

This review aims at providing a complete reference to the analytical synchrotron external shock afterglow models. It includes all the published models and spectral regimes, but also includes new derivations in the previously not well-studied models or spectral regimes. All the models are surveyed systematically, with typical model parameters calculated, temporal and spectral indices and their closure relations summarized in tables. It is designated as a complete reference tool for GRB afterglow observers to quickly identify the relevant models to interpret their broad-band data. In Section 2, we provide a general description of the synchrotron external shock models, which lay the foundation to derive any model discussed later. Section 3 summarizes all the models in four different phases: the reverse and forward shock models during the reverse shock crossing phase (§3.1), the forward shock models during the isotropic self-similar deceleration phase (§3.2), the forward shock models in the post-jet break phase (§3.3), and the forward shock models in the non-relativistic (§3.4) phase. For each model, the expressions of key parameters, including the three characteristic frequencies $\nu_a$ (self-absorption frequency), $\nu_m$ (the characteristic synchrotron frequency of the electrons at the minimum injection energy), and $\nu_c$ (the cooling frequency), and the peak synchrotron flux density $F_{\nu,\text{max}}$, are presented. The spectral index $\beta$ and the temporal index $\alpha$ (with the convention $F_\nu \propto \nu^{-\beta} t^{-\alpha}$, as well as their closure relations are presented in Tables 1-20. In Section 4, we describe how to make use of the models to calculate lightcurves, and derive all possible lightcurves (Fig.1-44) by allowing a wide range of parameters. We also draw typical lightcurves in the radio, optical and X-ray bands by adopting typical values of model parameters. Finally, we discuss the limitations of these simple analytical models in Section 5.
2. General description of the synchrotron external shock models of GRBs

The synchrotron external shock models \cite{Rees1992, Meszaros1993, Meszaros1997, Sari1998} describe the interaction between the GRB outflow and the circum-burst hydrogen medium (CBM). The physical parameters that enter the problem to determine the dynamics of blastwave deceleration include the “isotropic” energy $E$ (the total energy assuming that the outflow is isotropic), the initial Lorentz factor $\Gamma_0$, and the CBM density and its profile $n(R) \propto R^{-k}$, $0 \leq k < 4$ \cite{Blandford1976} (and see Sari 2006 for a discussion for the cases with $k \geq 4$), where $R$ is the radius from the central engine. As a result, these models are very generic, not depending on the details of the central engine activity and prompt $\gamma$-ray emission. There is another parameter, i.e. the magnetization of the outflow $\sigma$, that would slightly affect the dynamics of the system during the early phase of evolution \cite{Zhang2005, Mimica2009}. In this review, we limit ourselves to the regime of zero (or very low) magnetization. These matter-dominated ejecta are also called “fireballs”.

Assuming that a jet with opening angle $\theta_j$ is launched from the central engine, which lasts a duration $T$ with constant Lorentz factor $\Gamma_0$, the evolution of the a fireball jet includes four phases. The first phase is when a pair of shocks (forward and reverse) propagating into the CBM and the shell (with initial width $\Delta_0 = cT$), respectively \cite{Sari1995}. After the reverse shock crosses the shell, the blastwave quickly enters a self-similar deceleration phase described by the Blandford-McKee solution \cite{Blandford1976}. This is the second phase. Later, as the blastwave is decelerated enough, the $1/T$ cone becomes larger than the geometric cone defined by $\theta_j$, the afterglow enters the post-jet-break phase. Finally, the blastwave enters the Newtonian phase when the velocity is much smaller than speed of light. The dynamics is then described by the well-known Sedov solution widely used to study supernova remnants.

During all the phases, particles are believed to be accelerated from the forward shock front via the 1st-order Fermi acceleration mechanism. For

\footnote{These simplified assumptions are certainly not the case in reality, but may be a good approximation after the prompt emission phase when the ejecta irregularities are smoothed out after energy dissipation through internal shocks \cite{Rees1994, Kobayashi1997, Kumar2000, Maxham2009}.}
the reverse shock, particle acceleration occurs only during the shock crossing phase. No new particles are accelerated in the reverse-shocked region after the reverse shock crosses the ejecta shell. Assume a power-law distribution of the electrons 
\[ N(\gamma_e) d\gamma_e \propto \gamma_e^{-p} d\gamma_e \] (for \( \gamma_m \leq \gamma_e \leq \gamma_M \)) and consider radiative cooling of electrons and continuous injection of new electrons from the shock front, one can obtain a broken power-law electron spectrum, which leads to a multi-segment broken power-law photon spectrum at any epoch (Sari et al., 1998; Mészáros et al., 1998).

Assuming that a constant fraction \( \epsilon_e \) of the shock energy is distributed to electrons, one can derive the minimum injected electron Lorentz factor

\[ \gamma_m = g(p)\epsilon_e(\Gamma - 1)\frac{m_p}{m_e}, \] (1)

where \( \Gamma \) is the relative Lorentz factor between the unshocked region and the shocked region, which is the Lorentz factor of the blastwave for the forward shock, \( m_p \) is proton mass, \( m_e \) is electron mass, and the function \( g(p) \) takes the form

\[ g(p) \simeq \begin{cases} \frac{p-2}{p-1}, & p > 2; \\ \ln^{-1}(\gamma_M/\gamma_m), & p = 2; \end{cases} \] (2)

Here \( \gamma_M \) is the maximum electron Lorentz factor, which may be estimated by balancing the acceleration time scale and the dynamical time scale, i.e.

\[ \gamma_M \sim \frac{\Gamma t q_e B}{\zeta m_p c}, \] (3)

where \( \zeta \) is a parameter of order unity that describes the details of acceleration, \( t \) is the observational time, \( q_e \) is the electron charge, and \( B \) is the comoving magnetic field strength. We also assume that the magnetic energy density behind the shock is a constant fraction \( \epsilon_B \) of the shock energy density. This gives

\[ B = (8\pi e\epsilon_B)^{1/2}, \] (4)

where \( e \) is the energy density in the shocked region. If the electron energy has a harder spectral index \( 1 < p < 2 \), the minimum electron Lorentz factor would be derived as (Dai and Cheng, 2001; Bhattacharyya, 2001)

\[ \gamma_m = \left( \frac{2 - p}{p - 1} \frac{m_p}{m_e} \epsilon_e(\Gamma - 1)\gamma_M^{-2} \right)^{1/(p-1)} \] (5)
For synchrotron radiation, the observed radiation power and the characteristic frequency of an electron with Lorentz factor $\gamma_e$ are given by \cite{Rybicki1979}:

\begin{equation}
P(\gamma_e) \approx \frac{4}{3} \sigma_T c \Gamma^2 \gamma_e^2 B^2 \frac{1}{8\pi},
\end{equation}

\begin{equation}
\nu(\gamma_e) \approx \Gamma \gamma_e^2 \frac{q_e B}{2\pi m_e c},
\end{equation}

where the factors of $\Gamma^2$ and $\Gamma$ are introduced to transform the values from the rest frame of the shocked fluid to the frame of the observer.

The spectral power of individual electron, $P_\nu$ (power per unit frequency, in unit of erg Hz$^{-1}$ s$^{-1}$), varies as $\nu^{1/3}$ for $\nu < \nu(\gamma_e)$, and cuts off exponentially for $\nu > \nu(\gamma_e)$ \cite{Rybicki1979}. The peak power occurs at $\nu(\gamma_e)$, where it has the approximate value

\begin{equation}
P_{\nu,\text{max}} \approx \frac{P(\gamma_e)}{\nu(\gamma_e)} = \frac{m_e c^2 \sigma_T}{3q_e} \Gamma B.
\end{equation}

Note that $P_{\nu,\text{max}}$ does not depend on $\gamma_e$.

The life time of a relativistic electron with Lorentz factor $\gamma_e$ in the observer frame can be estimated as

\begin{equation}
\tau(\gamma_e) = \frac{\Gamma \gamma_e m_e c^2}{4 \sigma_T c \Gamma^2 \gamma_e^2 B^2 \frac{1}{8\pi}} = \frac{6\pi m_e c}{\Gamma \gamma_e \sigma_T B^2}.
\end{equation}

One can define a critical electron Lorentz factor $\gamma_c$ by setting $\tau(\gamma_e) = t$, i.e.,

\begin{equation}
\gamma_c = \frac{6\pi m_e c}{\Gamma \sigma_T B^2 t},
\end{equation}

where $t$ refers to the time in the observer frame. Above $\gamma_c$, cooling by synchrotron radiation becomes significant, so that the electron distribution shape is modified in the $\gamma_e > \gamma_c$ regime.

The electron Lorentz factors $\gamma_m$ and $\gamma_c$ defines two characteristic emission frequencies $\nu_m$ and $\nu_c$ in the synchrotron spectrum. A third characteristic frequency $\nu_a$, is defined by synchrotron self-absorption, below which the synchrotron photons are self-absorbed. There are two methods to calculate this frequency. The first one is to define $\nu_a$ by the condition that the photon
optical depth for self-absorption is unity (Rybicki and Lightman, 1979). A more convenient method (e.g. Sari and Piran, 1999b; Kobayashi and Zhang, 2003b) is to define \( \nu_a \) by equating the synchrotron flux and the flux of a blackbody, i.e.

\[
I^a_{\nu} (\nu_a) = I^{bb}_\nu (\nu_a) \simeq 2kT \cdot \frac{\nu_a^2}{c^2},
\]

where the blackbody temperature is

\[
kT = \max[\gamma_a, \min(\gamma_c, \gamma_m)]m_e c^2,
\]

and \( \gamma_a \) is the corresponding electron Lorentz factor of \( \nu_a \) for synchrotron radiation, i.e. \( \gamma_a = (2\pi m_e c^2/\Gamma q_e B)^{1/2} \) (derived from Eq. [7]). One can prove (Shen and Zhang, 2009) that the two methods are equivalent to each other, even though the coefficient may slightly differ within a factor of two.

In the afterglow phase, \( \nu_a \) is usually the smallest among the three frequencies. The broad-band synchrotron spectrum therefore falls into two broad categories depending on the order of \( \gamma_m \) and \( \gamma_c \), namely the fast cooling regime \( \gamma_m > \gamma_c \) or the slow cooling regime \( \gamma_m < \gamma_c \) (Sari et al., 1998).

In the slow cooling regime, the electron energy distribution is

\[
N(\gamma_e) = \begin{cases} 
C_1(p-1) \gamma_m^{p-1} \gamma_c^{-p}, & \gamma_m \leq \gamma_e \leq \gamma_c, \\
C_1(p-1) \gamma_m^{p-1} \gamma_c^{-p-1}, & \gamma_e > \gamma_c.
\end{cases}
\]

In the fast cooling regime, usually one has the approximation

\[
N(\gamma) = \begin{cases} 
C_2 \gamma_c \gamma_e^{-2}, & \gamma_c \leq \gamma_e \leq \gamma_m, \\
C_2 \gamma_m^{p-1} \gamma_c^{-p-1}, & \gamma_e > \gamma_m.
\end{cases}
\]

where \( C_1 \) and \( C_2 \) are normalization factors\(^2\).

For such an electron energy distribution, the observed synchrotron radiation flux density \( F_\nu \) can be expressed as

I. \( \nu_a < \nu_m < \nu_c \):

\(^2\)It is realized that the fast-cooling spectrum below injection can be harder than \(-2\) in a decaying magnetic field, which is the case for GRB afterglow emission (Uhm and Zhang, 2013b,a). We will discuss this more in Section 5.
\[ F_\nu = F_{\nu,\text{max}} \begin{cases} 
\left( \frac{\nu_m}{\nu_a} \right)^{1/3} \left( \frac{\nu}{\nu_a} \right)^2, & \nu < \nu_a; \\
\left( \frac{\nu_m}{\nu_a} \right)^{1/3}, & \nu_a < \nu < \nu_m; \\
\left( \frac{\nu_m}{\nu_m} \right)^{-1/2}, & \nu_m < \nu < \nu_c; \\
\left( \frac{\nu_m}{\nu_c} \right)^{-1/2} \left( \frac{\nu}{\nu_c} \right)^{-p/2}, & \nu > \nu_c; 
\end{cases} \quad (15) \]

II. \( \nu_a < \nu_c < \nu_m \):

\[ F_\nu = F_{\nu,\text{max}} \begin{cases} 
\left( \frac{\nu_m}{\nu_c} \right)^{1/3} \left( \frac{\nu}{\nu_a} \right)^2, & \nu < \nu_a; \\
\left( \frac{\nu_m}{\nu_c} \right)^{1/3}, & \nu_a < \nu < \nu_c; \\
\left( \frac{\nu_m}{\nu_m} \right)^{-1/2}, & \nu_c < \nu < \nu_m; \\
\left( \frac{\nu_m}{\nu_m} \right)^{-1/2} \left( \frac{\nu}{\nu_m} \right)^{p/2}, & \nu > \nu_m. 
\end{cases} \quad (16) \]

In general, there are six different orders among \( \nu_a, \nu_m \) and \( \nu_c \). Under extreme conditions they might be all possible. When \( \nu_a > \nu_c \), the electron energy distribution may be significantly modified (Gao et al., 2013), so that analytical models are no longer good approximations. Those cases are rare but not impossible, and we will leave out from this review. A detailed analysis can be found in Kobayashi et al. (2004) and Gao et al. (2013).

For the \( \nu_a < \nu_c \) regime, there is one more case, i.e.

III. \( \nu_m < \nu_a < \nu_c \):

\[ F_\nu = F_{\nu,\text{max}} \begin{cases} 
\left( \frac{\nu_m}{\nu_a} \right)^{(p+4)/2} \left( \frac{\nu}{\nu_a} \right)^2, & \nu < \nu_m; \\
\left( \frac{\nu_m}{\nu_a} \right)^{-(p-1)/2} \left( \frac{\nu}{\nu_a} \right)^{5/2}, & \nu_m < \nu < \nu_a; \\
\left( \frac{\nu_m}{\nu_m} \right)^{-(p-1)/2}, & \nu_a < \nu < \nu_c; \\
\left( \frac{\nu_m}{\nu_m} \right)^{-(p-1)/2} \left( \frac{\nu}{\nu_c} \right)^{-p/2}, & \nu > \nu_c. 
\end{cases} \quad (17) \]

In all the above expressions, \( F_{\nu,\text{max}} \) is the observed peak flux at luminosity distance \( D \) from the source, which can be estimated as (Sari et al., 1998):

\[ F_{\nu,\text{max}} \equiv N_e P_{\nu,\text{max}} / 4\pi D^2, \quad (18) \]
where $N_e$ is the total number of electrons in the emission region. For the forward shock emission, it is usually calculated as $N_e \sim \int_{R_0}^{R} 4\pi n(r)r^2 dr$, where $R_0$ is the central engine radius and $R$ is the radius from the center of central engine.

The instantaneous spectra described above do not depend on the hydrodynamical evolution of the shocks. However, in order to calculate the light curve at a given frequency, we need to know the temporal evolution of various quantities, such as the break frequencies $\nu_a$, $\nu_m$ and $\nu_c$ and the peak flux density $F_{\nu,\text{max}}$, which depend on the dynamics of the system. For the forward shock, the emission essentially depends on the temporal evolution of three quantities $\Gamma$, $R$ and $B$ (or the energy density $e$ if $\epsilon_B$ is assumed to be constant). In the next section, we will derive how $\Gamma$, $R$ and $e$ evolve as a function of $t$ for various systems and dynamical phases, and quantify the evolutions of the break frequencies $\nu_m$, $\nu_c$ and $\nu_a$, as well as the peak flux density $F_{\nu,\text{max}}$. We will then present the spectral and temporal indices ($\beta$ and $\alpha$) for all the spectral regimes of all the models, as well as the closure relations between $\alpha$ and $\beta$.

3. Analytical synchrotron external shock models

There are many variations of the external shock synchrotron models. First, during the reverse shock crossing phase, the dynamics of the blast-wave is complicated, and there are rich features in the reverse shock and forward shock lightcurves. Second, even after reverse shock crossing and when the blast-wave is in the self-similar deceleration phase, variations in the energy content of the blastwave (e.g. radiative loss or energy injection) or in the profile of the CBM (e.g. constant density ISM, a stratified wind, or a more general profile) would give very different lightcurves. Next, the collimation effect becomes important when the blastwave is decelerated enough so that the relativistic beaming $1/\Gamma$ cone is large enough to enclose a solid angle in which the anisotropic effect becomes significant. Finally, the blastwave eventually enters the Newtonian phase, when a different self-similar solution is reached. For each dynamical model, there could be many possible lightcurves in view of a range of initial spectral regime of the observing frequency, and the complicated evolutions of three characteristic frequencies and their relative orders.

In the following, we will discuss all these models based on the four dynamical phases outlined above: Phase 1: reverse shock crossing phase; Phase
2: relativistic, pre-jet-break self-similar deceleration phase; Phase 3: post-jet-break phase; Phase 4: Newtonian phase.

3.1. Phase 1: Reverse shock crossing phase

We consider a uniform and cold relativistic shell with isotropic energy $E$, lab-frame width $\Delta_0 = cT$, coasting with an initial Lorentz factor $\Gamma_0$. This shell sweeps into a circumburst hydrogen medium (CBM) with a proton number density profile $n = A R^{-k}$ ($0 \leq k < 4$). A pair of shocks are developed: a forward shock propagating into the CBM and a reverse shock propagating into the shell. The two shocks and the contact discontinuity separate the system into four regions: (1) the unshocked CBM (called Region 1 hereafter), (2) the shocked CBM (Region 2), (3) the shocked shell (Region 3), and (4) the unshocked shell (Region 4). Using the relativistic shock jump conditions (Blandford and McKee, 1976) and assuming equal pressure and velocity in the blastwave region (Regions 2 and 3), i.e., $e_2 = e_3$ and $\gamma_2 = \gamma_3$, the values of the bulk Lorentz factor $\Gamma$, the radius $R$, and the energy density $e$ in the shocked regions can be estimated as functions of $n_1$, $n_4$, and $\Gamma_0 = \gamma_4$, where $n_i$, $e_i$ and $\gamma_i$ are the comoving number densities, energy density and Lorentz factors for Region $i$.

Analytical results can be obtained in both relativistic and Newtonian reverse shock limits. These two cases are defined by comparing a parameter $f \equiv n_4/n_1$ (ratio of the number densities between the unshocked shell and the unshocked CBM) and $\gamma_4^2$ (Sari and Piran, 1995). If $f \gg \gamma_4^2$, the reverse shock is Newtonian (NRS, thin shell case), and if $f \ll \gamma_4^2$, the reverse shock is relativistic (RRS, thick shell case). The strength of the reverse shock depends on the relative Lorentz factor between Region 3 and Region 4, i.e.

$$\bar{\gamma}_{34} = \gamma_3 \gamma_4 (1 - \sqrt{1 - 1/\gamma_3^2} \sqrt{1 - 1/\gamma_4^2}).$$

For $\gamma_2, \gamma_4 \gg 1$ and assuming $\gamma_2 = \gamma_3$, $\bar{\gamma}_{34}$ can be expressed as $\bar{\gamma}_{34} \simeq 1/\sqrt{2} \gamma_4^{1/2} f^{-1/4}$ for a RRS, while $\bar{\gamma}_{34} - 1 \simeq 4/3 \gamma_4^2 f^{-1}$ for a NRS.

The Phase 1 ends at the reverse shock crossing time

$$t_x = \max(t_{\text{dec}}, T),$$

---

$^3$Strictly speaking, such a situation cannot be achieved since it violates energy conservation (Uhm, 2011; Uhm et al., 2012). Nonetheless, for a short-lived reverse shock (finite width $\Delta_0$ with constant $\Gamma_0$), such an approximation is good enough to delineate the dynamical evolution of the system.

11
where $T$ is the duration of the burst, and

$$
t_{\text{dec}} = \left( \frac{(3 - k)E}{2^{4-k} \pi A m p_0^{8-2k} c^{5-k}} \right)^{\frac{1}{2k}} 
$$

(21) is the deceleration time of the ejecta for an impulsive injection of fireball with energy $E$ and initial Lorentz factor $\Gamma_0$, which corresponds to the time when the mass collected from the CBM is about $1/\Gamma$ of the rest mass entrained in the ejecta. For thin shells, one has $t_\times = t_{\text{dec}}$, while for thick shells, one has $t_\times = T$ (Kobayashi et al., 1999).

In the following, we discuss the synchrotron emission properties for four models: thin shell forward shock model, thin shell reverse shock model, thick shell forward shock model, and thick shell reverse shock model.

### 3.1.1. Thin Shell Forward Shock Model

In the thin shell models, the reverse shock is Newtonian, so that $\gamma_2 \simeq \gamma_4 = \Gamma_0$. We consider the dynamics of Region 2, i.e.

$$
\gamma_2 = \Gamma_0, \quad R_2 = 2c\Gamma_0^2 t.
$$

In general, the expressions for an arbitrary density profile index $k$ can be derived. The two most commonly used models are the constant density interstellar medium (ISM) model ($k = 0$) and the free stratified wind model ($k = 2$). Hereafter we will explicitly derive the expressions for these two density profiles.

For the constant density case ($n_1 = n_0$) with electron energy spectral index $p > 2$, one has

$$
\nu_m = 3.1 \times 10^{16} \text{ Hz } \hat{z}^{-1} \frac{G(p)}{G(2.3)} \Gamma_0^{4} n_{0,0}^{1/2} n_{e,-1}^{1/2} \epsilon_{B,-2},
$$

$$
\nu_c = 4.1 \times 10^{16} \text{ Hz } \hat{z} \Gamma_0^{-4} n_{0,0}^{3/2} \epsilon_{B,-2}^{3/2},
$$

$$
F_{\nu,\text{max}} = 1.1 \times 10^4 \text{ µJy } \hat{z}^{-2} \Gamma_0^{8} n_{0,0}^{3/2} \epsilon_{B,-2}^{2} D_{28}^{-2/3},
$$

$$
\nu_a = 5.7 \times 10^9 \text{ Hz } \hat{z}^{-8/5} \frac{g^{I}(p)}{g^{I}(2.3)} \Gamma_0^{4/5} n_{0,0}^{1/5} \epsilon_{e,-1}^{1/5} \epsilon_{B,-2}^{3/5}, \quad \nu_a < \nu_m < \nu_c
$$

$$
\nu_a = 8.3 \times 10^{12} \text{ Hz } \hat{z}^{-\frac{p+6}{p+4}} \frac{g^{II}(p)}{g^{II}(2.3)} \Gamma_0^{4(p+2)} n_{0,0}^{p+6} \epsilon_{e,-1}^{2(p+1)} \epsilon_{B,-2}^{p+4}, \quad \nu_m < \nu_a < \nu_c
$$

$$
\nu_a = 4.9 \times 10^{9} \text{ Hz } \hat{z}^{-13/5} \frac{g^{III}(p)}{g^{III}(2.3)} \Gamma_0^{28/5} n_{0,0}^{9/5} \epsilon_{B,-2}^{6/5}, \quad \nu_a < \nu_c < \nu_m
$$

(22)
where $G(p)$ and $g^i(p)$ are numerical constants related to $p$, and $\dot{z} = (1 + z)/2$ is the redshift correction factor. The explicit expressions of $G(p)$ and $g^i(p)$ are complicated, and we present them (along with the $p$-dependent coefficients in all other models) in Appendix A.

When $1 < p < 2$, expressions of $\nu_c$ and $F_{\nu,\text{max}}$ remain the same as the $p > 2$ case (also apply to other models discussed later). Other expressions are modified as follows

$$\nu_m = 3.2 \times 10^{14} \text{ Hz } \dot{z}^{-1} \frac{g^{IV}(p)}{g^{IV}(1.8)} \Gamma_p^{1/2} \frac{A_{s,-1}^{1/2} \Gamma_0}{2} \frac{A_{s,-1}^{1/2}}{2} \frac{\epsilon_{e,-1}^{1/2} B_{-2}^{1/2}}{2} ;$$

$$\nu_a = 4.6 \times 10^{10} \text{ Hz } \dot{z}^{-8/5} \frac{g^{V}(p)}{g^{V}(1.8)} \Gamma_p^{1/2} \frac{A_{s,-1}^{1/2} \Gamma_0}{2} \frac{A_{s,-1}^{1/2}}{2} \frac{\epsilon_{e,-1}^{1/2} B_{-2}^{1/2}}{2} ; \quad \nu_a < \nu_m < \nu_c$$

$$\nu_a = 2.0 \times 10^{10} \text{ Hz } \dot{z}^{-13/5} \frac{g^{VI}(p)}{g^{VI}(1.8)} \Gamma_p^{1/2} \frac{A_{s,-1}^{1/2} \Gamma_0}{2} \frac{A_{s,-1}^{1/2}}{2} \frac{\epsilon_{e,-1}^{1/2} B_{-2}^{1/2}}{2} ; \quad \nu_m < \nu_a < \nu_c$$

$$\nu_a = 4.0 \times 10^9 \text{ Hz } \dot{z}^{-13/5} \frac{g^{VII}(p)}{g^{VII}(1.8)} \Gamma_p^{1/2} \frac{A_{s,-1}^{1/2} \Gamma_0}{2} \frac{A_{s,-1}^{1/2}}{2} \frac{\epsilon_{e,-1}^{1/2} B_{-2}^{1/2}}{2} ; \quad \nu_a < \nu_c < \nu_m$$

(23)

For the wind model ($k = 2$), one can express the density profile as $n_1 = AR^{-2}$ with $A = \dot{M}/4\pi m_p v_w = 3 \times 10^{35} A \text{ cm}^{-1}$. $(\dot{M}) = (\dot{M}/10^5 M_\odot \text{ yr}^{-1})(v_w/10^3 \text{ km s}^{-1})^{-1}$ [Dai and Lu, 1998; Chevalier and Li, 1999; 2000]. For $p > 2$, one has

$$\nu_m = 8.7 \times 10^{16} \text{ Hz } \frac{G(p)}{G(2.3)} A_{s,-1}^{1/2} \Gamma_p^{1/2} \frac{A_{s,-1}^{1/2} \Gamma_0}{2} \frac{A_{s,-1}^{1/2}}{2} \frac{\epsilon_{e,-1}^{1/2} B_{-2}^{1/2}}{2} ;$$

$$\nu_c = 1.8 \times 10^{15} \text{ Hz } \dot{z}^{-2} \Gamma_p^{1/2} \frac{A_{s,-1}^{3/2} \Gamma_0}{2} \frac{A_{s,-1}^{3/2}}{2} \frac{D_{28}^{-1}}{2} ;$$

$$F_{\nu,\text{max}} = 7.5 \times 10^5 \mu \text{ Jy } \dot{z} A_{s,-1}^{3/2} \Gamma_0^{1/2} \frac{A_{s,-1}^{3/2}}{2} \frac{D_{28}^{-1}}{2} ;$$

$$\nu_a = 5.9 \times 10^{10} \text{ Hz } \frac{g^{VIII}(p)}{g^{VIII}(2.3)} \Gamma_p^{1/2} \frac{A_{s,-1}^{1/2} \Gamma_0}{2} \frac{A_{s,-1}^{1/2}}{2} \frac{\epsilon_{e,-1}^{1/2} B_{-2}^{1/2}}{2} ; \quad \nu_a < \nu_m < \nu_c$$

$$\nu_a = 4.7 \times 10^{13} \text{ Hz } \frac{g^{IX}(p)}{g^{IX}(2.3)} \Gamma_p^{1/2} \frac{A_{s,-1}^{1/2} \Gamma_0}{2} \frac{A_{s,-1}^{1/2}}{2} \frac{\epsilon_{e,-1}^{1/2} B_{-2}^{1/2}}{2} ; \quad \nu_a < \nu_m < \nu_c$$

$$\nu_a = 4.1 \times 10^{11} \text{ Hz } \dot{z}^{8/5} \frac{g^{X}(p)}{g^{X}(2.3)} \Gamma_p^{1/2} \frac{A_{s,-1}^{1/2} \Gamma_0}{2} \frac{A_{s,-1}^{1/2}}{2} \frac{\epsilon_{e,-1}^{1/2} B_{-2}^{1/2}}{2} ; \quad \nu_a < \nu_c < \nu_m$$

(24)

For $1 < p < 2$, one has

$$\nu_m = 1.2 \times 10^{15} \text{ Hz } \dot{z}^{2/5} \frac{g^{XI}(p)}{g^{XI}(1.8)} \frac{A_{s,-1}^{1/2} \Gamma_0}{2} \frac{A_{s,-1}^{1/2}}{2} \frac{\epsilon_{e,-1}^{1/2} B_{-2}^{1/2}}{2} ;$$

13
\[
\nu_a = 4.2 \times 10^{11} \text{ Hz } \hat{\nu}^{p/2} \frac{g^{XII}(p)}{g^{XII}(1.8)} \Gamma_{0.2}^{11p/2-6} A^{2p+2p/2 \xi_{0.1}}_{\nu, -1} \epsilon_{e, -1}^{1/2} \epsilon_{B, -2}^{1/2}, \nu_a < \nu_m < \nu_c
\]

\[
\nu_a = 1.2 \times 10^{13} \text{ Hz } \hat{\nu}^{2p/3} \frac{g^{XIII}(p)}{g^{XIII}(1.8)} \Gamma_{0.2}^{11p/2-6} A_{\nu, -1}^{2p+2p/2 \xi_{0.1}} \epsilon_{e, -1}^{1/2} \epsilon_{B, -2}^{1/2}, \nu_m < \nu_a < \nu_m
\]

\[
\nu_a = 3.4 \times 10^{11} \text{ Hz } \hat{\nu}^{8/5} \frac{g^{XIV}(p)}{g^{XIV}(1.8)} \Gamma_{0.2}^{-8/5} A_{\nu, -1}^{2p+2p/2 \xi_{0.1}} \epsilon_{e, -1}^{1/2} \epsilon_{B, -2}^{1/2}, \nu_a < \nu_c < \nu_m
\]

(25)

The \( \alpha \) and \( \beta \) values and their closure relations of the models described in this section (with convention \( F_\nu \propto t^{-\alpha} \nu^{-\beta} \)) are collected in Tables 1 and 2.

We note that the temporal evolution of the characteristic frequencies and the peak flux density are important to judge the relevant models. Hereafter at the end of each subsection, we summarize these dependences for easy identification.

For this regime (thin-shell forward shock model during shock crossing) and for \( p > 2 \), \( \nu_m \propto t^0 \) (\( t^{-1} \)), \( \nu_c \propto t^{-2} \) (\( t^1 \)), \( F_{\nu, \text{max}} \propto t^3 \) (\( t^0 \)) for the ISM (wind) models, respectively. The temporal evolution of \( \nu_a \) depends on the relative orders between \( \nu_a, \nu_m \) and \( \nu_c \). For \( 1 < p < 2 \), \( \nu_c \) and \( F_{\nu, \text{max}} \) evolutions are the same as \( p > 2 \) cases, while \( \nu_m \propto t^0 \) (\( t^3 \)) for the ISM (wind) models, respectively.

3.1.2. Thin Shell Reverse Shock Model

The scalings of this regime have been derived by [Kobayashi (2000)]. During the reverse shock crossing phase, the blastwave dynamics is same as the thin-shell forward shock case. However, the emission properties of the reverse shock depend on \( \gamma_{34} \) and \( n_4 \), while those of the forward shock depend on \( \gamma_2 \) and \( n_1 \). Following the similar procedure described above, one can derive the expressions of various parameters of this model. For the ISM model (\( k = 0 \)) and \( p > 2 \), one has

\[
\nu_m = 1.9 \times 10^{12} \text{ Hz } \hat{\nu}^{-7} \frac{G(p)}{G(2.3)} E_{52}^{-2} \Gamma_{0.2}^{18} \epsilon_{0.0}^{5/2} \epsilon_{e, -1}^{1/2} \epsilon_{B, -2}^{1/2},
\]

\[
\nu_c = 4.1 \times 10^{16} \text{ Hz } \hat{\nu}^{-1/2} E_{52}^{-2} \Gamma_{0.2}^{18} \epsilon_{0.0}^{5/2} \epsilon_{e, -1}^{1/2} \epsilon_{B, -2}^{1/2},
\]

\[
F_{\nu, \text{max}} = 9.1 \times 10^{5} \mu \text{ Jy } \hat{\nu}^{-1/2} E_{52}^{-2} \Gamma_{0.2}^{18} \epsilon_{0.0}^{5/2} \epsilon_{e, -1}^{1/2} \epsilon_{B, -2}^{1/2} D_{28}^{3/2},
\]

\[
\nu_a = 1.0 \times 10^{13} \text{ Hz } \hat{\nu}^{13/10} g^{I}(p) g^{I}(2.3) E_{52}^{13/10} \Gamma_{0.2}^{18} \epsilon_{0.0}^{5/2} \epsilon_{e, -1}^{1/2} \epsilon_{B, -2}^{1/2} D_{28}^{3/2}, \nu_a < \nu_m < \nu_c
\]
Table 1: The temporal decay index $\alpha$ and spectral index $\beta$ in thin shell forward shock model with $\nu_a < \min(\nu_m, \nu_c)$.

| ISM | slow cooling | | | | p > 2 | 1 < p < 2 |

Table 2: The temporal decay index $\alpha$ and spectral index $\beta$ in thin shell forward shock model in the $\nu_m < \nu_a < \nu_c$ regime.

| $\beta$ | $p > 2$ | $1 < p < 2$ |
|---------|---------|--------------|
| $\alpha$ | $\alpha(\beta)$ | $\alpha(\beta)$ |

**ISM** slow cooling

| $\nu < \nu_m$ | $\alpha = \beta$ | $\alpha = \beta$ |
|----------------|------------------|------------------|
| $\nu_m < \nu < \nu_a$ | $\alpha = \frac{4\beta}{5}$ | $\alpha = \frac{4\beta}{5}$ |
| $\nu_a < \nu < \nu_c$ | $\alpha = 1$ | $\alpha = 1$ |
| $\nu > \nu_c$ | $\alpha = \beta - 1$ | $\alpha = \beta - 1$ |

**Wind** slow cooling

| $\nu < \nu_m$ | $\alpha = \beta$ | $\alpha = \beta$ |
|----------------|------------------|------------------|
| $\nu_m < \nu < \nu_a$ | $\alpha = \frac{2}{5}$ | $\alpha = \frac{2}{5}$ |
| $\nu_a < \nu < \nu_c$ | $\alpha = \frac{p}{2}$ | $\alpha = \frac{p}{2}$ |
| $\nu > \nu_c$ | $\alpha = \beta - 1$ | $\alpha = \beta - 1$ |

For $1 < p < 2$, one has

$$\nu_a = 4.7 \times 10^{12} \text{ Hz} \quad \frac{\hat{\nu}^{3-7\beta}}{g^{IV}(2.3)} \quad \frac{E^{3-2\beta}}{\Gamma_0^{\nu-12}} \quad \frac{n_0^{\beta}}{t_0^{\nu-1}} \quad \frac{\epsilon_{e-1} d^2}{\epsilon_{B-2}} \quad \nu_m < \nu_a < \nu_c$$

$$\nu_a = 7.0 \times 10^{10} \text{ Hz} \quad \frac{\hat{\nu}^{-17/10}}{g^{VI}(2.3)} \quad \frac{E^{3/10-19/5}}{\Gamma_0^{3/2-6/5}} \quad \frac{n_0^{\nu} \epsilon_{B-2}^{d^2}}{t_0^{1/2}} \quad \nu_a < \nu_c < \nu_m$$

(26)

For $p > 2$, one has

$$\nu_m = 1.8 \times 10^9 \text{ Hz} \quad \frac{\hat{\nu}^{-5\beta}}{g^{IV}(1.8)} \quad \frac{E^{3-2\beta}}{\Gamma_0^{\nu-12}} \quad \frac{n_0^{\beta}}{t_0^{\nu-1}} \quad \frac{\epsilon_{e-1} d^2}{\epsilon_{B-2}} \quad \nu_m < \nu_a < \nu_c$$

$$\nu_a = 2.7 \times 10^{11} \text{ Hz} \quad \frac{\hat{\nu}^{-5\beta}}{g^{VI}(1.8)} \quad \frac{E^{3-2\beta}}{\Gamma_0^{\nu-12}} \quad \frac{n_0^{\beta}}{t_0^{\nu-1}} \quad \frac{\epsilon_{e-1} d^2}{\epsilon_{B-2}} \quad \nu_m < \nu_a < \nu_c$$

(27)

For the wind model ($k = 2$) and $p > 2$, one has

$$\nu_m = 3.3 \times 10^{15} \text{ Hz} \quad \frac{\hat{\nu}^{-2}}{G^{(2.3)}} \quad \frac{E^{2\beta}}{\Gamma_0^{\nu-12}} \quad \frac{n_0^{\beta}}{t_0^{\nu-1}} \quad \frac{\epsilon_{e-1} d^2}{\epsilon_{B-2}}$$
\[
\nu_c = 1.8 \times 10^{15} \text{Hz} \quad \frac{\dot{z}^2 \Gamma_{0,2}^2 A_{*, 1}^{-3/2} \epsilon_{B, 2}^{-3/2}}{t_2},
\]
\[
F_{\nu, \text{max}} = 1.3 \times 10^7 \mu\text{Jy} \quad \frac{\dot{z}^{3/2} E_{52}^{1/2} A_{*, 1}^{-1}}{2 D_{28}^{1/2} t_2^{-1/2}},
\]
\[
\nu_a = 1.7 \times 10^{12} \text{Hz} \quad \frac{g^{v, \text{III}}(p)}{g^{v, \text{III}}(2, 3)} \frac{E_{52}^{13/10} \Gamma_{0, 2}^{26/5} A_{*, 1}^{-1/2} \epsilon_{e, -1}^{1/5} \epsilon_{B, 2}^{-23/10}}{t_2}, \quad \nu_a < \nu_m < \nu_c
\]
\[
\nu_a = 5.9 \times 10^{13} \text{Hz} \quad \frac{g^{v, \text{X}}(p)}{g^{v, \text{X}}(2, 3)} \frac{E_{52}^{3/10} \Gamma_{0, 2}^{-1/10} A_{*, 1}^{-3/2} \epsilon_{B, 2}^{-23/10}}{t_2}, \quad \nu_a < \nu_c < \nu_m
\]

For \(1 < p < 2\), one has
\[
\nu_m = 2.0 \times 10^{13} \text{Hz} \quad \frac{g^{v, \text{X}}(p)}{g^{v, \text{X}}(2, 3)} \frac{E_{52}^{13/10} \Gamma_{0, 2}^{26/5} A_{*, 1}^{-1/2} \epsilon_{e, -1}^{1/5} \epsilon_{B, 2}^{-23/10}}{t_2}, \quad \nu_a < \nu_m < \nu_c
\]
\[
\nu_a = 1.8 \times 10^{13} \text{Hz} \quad \frac{g^{v, \text{X}}(p)}{g^{v, \text{X}}(2, 3)} \frac{E_{52}^{3/10} \Gamma_{0, 2}^{-1/10} A_{*, 1}^{-3/2} \epsilon_{B, 2}^{-23/10}}{t_2}, \quad \nu_a < \nu_m < \nu_c
\]
\[
\nu_a = 1.9 \times 10^{13} \text{Hz} \quad \frac{g^{v, \text{X}}(p)}{g^{v, \text{X}}(2, 3)} \frac{E_{52}^{13/10} \Gamma_{0, 2}^{-1/10} A_{*, 1}^{-3/2} \epsilon_{B, 2}^{-23/10}}{t_2}, \quad \nu_a < \nu_m < \nu_c
\]

After the NRS crosses the shell, the Lorentz factor of the shocked shell may be assumed to have a general power-law decay behavior \(\gamma_3 \propto r^{-g}\) (Mészáros and Rees, 1999; Kobayashi and Sari, 2000). The dynamical behavior in Region 3 could be expressed with some scaling-laws:
\[
\gamma_3 \propto t^{-9/(1+2g)}, n_3 \propto t^{-6(3+g)/7(1+2g)},
\]
\[
e_3 \propto t^{-8(3+g)/7(1+2g)}, \quad r \propto t^{1/(1+2g)}, N_{e, 3} \propto t^0,
\]

For the ISM case \((k = 0)\), one may adopt \(g \simeq 2\) (Kobayashi, 2000; Zou et al., 2005). For \(p > 2\), one has
\[
\nu_m = 8.5 \times 10^{11} \text{Hz} \quad \frac{G(p)}{G(2, 3)} \frac{E_{52}^{19/35} \Gamma_{0, 2}^{-174/35} n_{0, 0}^{-1/70} \epsilon_{B, 2}^{-1/2} t_2^{-54/35}}{t_2},
\]
\[
\nu_{\text{cut}} = 4.3 \times 10^{16} \text{Hz} \quad \frac{E_{52}^{19/35} \Gamma_{0, 2}^{-292/105} n_{0, 0}^{-283/210} \epsilon_{B, 2}^{-3/2} t_2^{-54/35}}{t_2},
\]

(28)
\[ F_{\nu, \text{max}} = 7.0 \times 10^5 \mu \text{Jy} \nu \zeta^{69/35} E_{52}^{139/105} \Gamma_{0.2}^{167/105} n_{0.0}^{37/210} \epsilon_{B,-2}^{1/2} D_{28}^{-2} t_2^{-34/35}, \]

\[
\nu_a = 1.4 \times 10^{13} \text{ Hz} \nu \zeta^{73/175} g^{\nu}(p) E_{52}^{69/175} \Gamma_{0.2}^{8/175} n_{0.0}^{71/175} \epsilon_{e,-1}^{1/5} \epsilon_{B,-2}^{-102/175}, \nu_a < \nu_m < \nu_c
\]

\[
\nu_a = 3.7 \times 10^{12} \text{ Hz} \nu \zeta^{49p-36} \frac{g^{\nu}(p)}{g^{\nu}(2.3)} E_{52}^{2(9p+29)} \Gamma_{0.2}^{11/35(p+4)} n_{0.0}^{24p+1} \epsilon_{e,-1}^{1/5} \epsilon_{B,-2}^{-2(9p+4)} t_2^{-35(p+4)}, \nu_m < \nu_a < \nu_c
\]

Here \( \nu_{\text{cut}} \) is the cut-off frequency of the synchrotron spectrum, which is different from the traditional \( \nu_c \). After reverse shock crossing, no new electrons are accelerated. The maximum electron energy is defined by \( \nu_m \), which is calculated by \( \nu \) at the shock crossing time with correction due to adiabatic expansion (Kobayashi, 2000). In this case, fast cooling is not relevant, so there are only two regimes, i.e., \( \nu_a < \nu_m < \nu_{\text{cut}} \) and \( \nu_m < \nu_a < \nu_{\text{cut}} \).

For \( 1 < p < 2 \), again the expressions of \( \nu_{\text{cut}} \) and \( F_{\nu, \text{max}} \) remain the same, and other parameters are

\[
\nu_m = 6.8 \times 10^{11} \text{ Hz} \nu \zeta^{19/35} g^{\nu}(p) E_{52}^{69} \Gamma_{0.2}^{109p-144} n_{0.0}^{71-36p} \epsilon_{e,-1}^{2-p} \epsilon_{B,-2}^{-1} t_2^{-35}, \nu_a < \nu_m < \nu_{\text{cut}}
\]

\[
\nu_a = 1.3 \times 10^{13} \text{ Hz} \nu \zeta^{73/175} g^{\nu}(p) E_{52}^{69} \Gamma_{0.2}^{191p-366} n_{0.0}^{459p-634} \epsilon_{e,-1}^{2-p} \epsilon_{B,-2}^{-1} t_2^{-35}, \nu_m < \nu_a < \nu_{\text{cut}}
\]

\[
\nu_a = 3.7 \times 10^{12} \text{ Hz} \nu \zeta^{19p-36} \frac{g^{\nu}(p)}{g^{\nu}(2.3)} E_{52}^{2(9p+29)} \Gamma_{0.2}^{11/35(p+4)} n_{0.0}^{24p+1} \epsilon_{e,-1}^{2-p} \epsilon_{B,-2}^{-2(9p+4)} t_2^{-35(p+4)},
\]

For the wind model \( (k = 2) \), one could adopt \( g \approx 1 \) (Zou et al., 2005).

For \( p > 2 \), one has

\[
\nu_m = 1.4 \times 10^{11} \text{ Hz} \nu \zeta^{6/7} \frac{G(p)}{G(2.3)} E_{52}^{6/7} A_{s,-1}^{15/14} \Gamma_{0.2}^{()-24/7} n_{0.0}^{2} \epsilon_{B,-2}^{1/2} t_2^{-13/7}, \nu_a < \nu_m < \nu_{\text{cut}}
\]

\[
\nu_{\text{cut}} = 7.4 \times 10^{10} \text{ Hz} \nu \zeta^{6/7} E_{52}^{20/7} A_{s,-1}^{61/14} \epsilon_{B,-2}^{-3/2} t_2^{-13/7}
\]

\[
F_{\nu, \text{max}} = 1.6 \times 10^{6} \mu \text{Jy} \nu \zeta^{44/21} E_{52}^{23/21} A_{s,-1}^{17/14} \epsilon_{B,-2}^{1/2} D_{28}^{-2} t_2^{-23/21},
\]

18
\[ \nu_a = 5.5 \times 10^{14} \text{ Hz} \ z^{-8/35} \frac{g^{XII}(p)}{g^{XII}(2,3)} E_{52}^{12/35} \Gamma_{0,2}^{48/35} A_{s,-1}^{8/7} e_{e,-1}^{1/5} \epsilon_{B,-2}^{23/35}, \quad \nu_a < \nu_m < \nu_{\text{cut}} \]

\[ \nu_a = 5.5 \times 10^{14} \text{ Hz} \ z^{\frac{6p-4}{7(p+1)}} \frac{g^{XI}(p)}{g^{XII}(2,3)} E_{52}^{16-29p} \Gamma_{0,2}^{16-29p} A_{s,-1}^{50-5p} e_{e,-1}^{20(p-1)} \epsilon_{B,-2}^{2(p+1)} t_2^{52 + 24(p+1)}, \quad \nu_m < \nu_a < \nu_{\text{cut}} \]

For \( 1 < p < 2 \), \( \nu_a \) and \( F_{\nu,\text{max}} \) remain the same, and

\[ \nu_a = 5.5 \times 10^{14} \text{ Hz} \ z^{\frac{6}{7}} \frac{g^{XII}(p)}{g^{XII}(1.8)} E_{52}^{13p-20} \Gamma_{0,2}^{45p-66} A_{s,-1}^{47-26p} e_{e,-1}^{20-2p} \epsilon_{B,-2}^{2(p-1)} t_2^{\frac{1}{p-1} - \frac{13}{7}}, \quad \nu_a < \nu_m < \nu_{\text{cut}} \]

\[ \nu_a = 2.8 \times 10^{14} \text{ Hz} \ z^{-8/35} \frac{g^{XIII}(p)}{g^{XIII}(1.8)} E_{52}^{34-59p} \Gamma_{0,2}^{35(1-p)} A_{s,-1}^{74-53p} e_{e,-1}^{70(p-1)} \epsilon_{B,-2}^{2(p-1)} t_2^{\frac{1}{p-1} - \frac{1}{2}}, \quad \nu_a < \nu_m < \nu_{\text{cut}} \]

\[ \nu_a = 1.6 \times 10^{13} \text{ Hz} \ z^{\frac{6p-4}{7(p+1)}} \frac{g^{XIV}(p)}{g^{XIV}(1.8)} E_{52}^{13p-18} \Gamma_{0,2}^{58+5p} A_{s,-1}^{46-13p} e_{e,-1}^{50} \epsilon_{B,-2}^{2(p+1)} t_2^{\frac{2}{p+1} - \frac{13p+24}{7(p+1)}}, \quad \nu_m < \nu_a < \nu_{\text{cut}} \]

The \( \alpha \) and \( \beta \) values and their closure relations for the thin shell reverse shock models are presented in Tables \[3\] and \[4\] (for pre-shock-crossing), and Tables \[5\] and \[6\] (for post-shock-crossing).

For this regime (thin-shell reverse shock model during shock crossing), for \( p > 2 \), one has \( \nu_m \propto \nu_c^6 \ (t^1) \), \( \nu_c \propto t^{-2} \ (t^1) \), \( F_{\nu,\text{max}} \propto t^{-3/2} \ (t^{-1/2}) \) for the ISM (wind) models, respectively. For \( 1 < p < 2 \), \( \nu_c \) and \( F_{\nu,\text{max}} \) evolutions are the same as \( p > 2 \) cases, while \( \nu_m \propto \nu_c^{6/5} \ (t^{1/5}) \) for the ISM (wind) models, respectively.

After shock crossing, \( \nu_m \propto \nu_{\text{cut}} \propto t^{-54/35} \ (t^{-13/7}) \), \( F_{\nu,\text{max}} \propto t^{-34/35} \ (t^{-23/21}) \) for the ISM (wind) models, respectively.

3.1.3. Thick Shell Forward Shock Model

For the thick shell case, the reverse shock becomes relativistic early on during shock crossing. In this relativistic shock crossing phase, the blastwave dynamics can be characterized as

\[ \gamma_2 = \gamma_3 = \frac{1}{\sqrt{2}} \left( \frac{t^{3-k}}{L_0} \right) \left( \frac{1}{\Delta_0} \right)^{\frac{1}{2} - \frac{k}{4 - 4k}} \left( \frac{t}{T} \right)^{\frac{k-2}{2(k-4)}} \Delta_0^{\frac{k-2}{4-k}}, \quad R = 2c_2 \gamma_2^2 \]

(35)

where $l = \left(\frac{(3-k)E}{2\pi A_n c^2}\right)^{\frac{1}{2}}$ is the Sedov length, and $T = \frac{\Delta u_c}{c}$ is the shock crossing time (Yi et al. 2013).

For the ISM model and when $p > 2$, the forward shock emission can be characterized by

$$
\nu_m = 1.0 \times 10^{16} \text{ Hz} \left(\frac{G(p)}{G(2.3)}\right)^{1/2} E^{1/2}_{52} \Delta_{0.13}^{-1/2} \epsilon_{e,-1}^{1/2} B_{-2}^{-1/2},
$$

$$
\nu_c = 1.2 \times 10^{17} \text{ Hz} E^{1/2}_{52} \Delta_{0.13}^{-1/2} \epsilon_{e,-1}^{-1/2} B_{-2}^{-1},
$$

$$
F_{\nu,\text{max}} = 1.2 \times 10^{3} \mu\text{Jy} \Delta_{0.13}^{-1/2} \epsilon_{e,-1}^{-1/2} D_{28}^{-2},
$$

$$
\nu_a = 3.6 \times 10^{9} \text{ Hz} \Delta_{0.13}^{-1/5} \epsilon_{e,-1}^{-1/5} B_{-2}^{-1/2}, \quad \nu_a < \nu_m < \nu_c
$$

$$
\nu_a = 3.9 \times 10^{12} \text{ Hz} \Delta_{0.13}^{-1/5} \epsilon_{e,-1}^{-1/5} B_{-2}^{-1/2}, \quad \nu_m < \nu_a < \nu_c
$$

$$
\nu_a = 1.0 \times 10^{9} \text{ Hz} \Delta_{0.13}^{-7/10} \epsilon_{e,-1}^{-1/5} B_{-2}^{-1/2}, \quad \nu_a < \nu_c < \nu_m
$$

For $1 < p < 2$, one has ($\nu_c$ and $F_{\nu,\text{max}}$ remain the same)

$$
\nu_m = 8.6 \times 10^{13} \text{ Hz} \Delta_{0.13}^{-1/5} \epsilon_{e,-1}^{-1/5} B_{-2}^{-1/2},
$$

$$
\nu_a = 3.2 \times 10^{10} \text{ Hz} \Delta_{0.13}^{-7/10} \epsilon_{e,-1}^{-1/5} B_{-2}^{-1/2},
$$

22
\[ \nu_a = 9.3 \times 10^{11} \text{ Hz} \ \cong \ \zeta = 3.1^{14} \frac{g^{VI}(p)}{g^{VI}(1.8)} E_{52}^{\nu_0} A_{13}^{\nu_1} n_{0,0}^{\nu_2} \zeta_0^{\nu_3} \epsilon_0^{\nu_4} \epsilon_{-1}^{\nu_5} B_{-2}^{\nu_6}, \]

\[ \nu_a = 8.5 \times 10^8 \text{ Hz} \ \cong \ \zeta = 6^{10} \frac{g^{VII}(p)}{g^{VII}(1.8)} E_{52}^{\nu_0} A_{13}^{\nu_1} n_{0,0}^{\nu_2} \zeta_0^{\nu_3} \epsilon_0^{\nu_4} \epsilon_{-1}^{\nu_5} B_{-2}^{\nu_6}, \]

For the wind model and \( p > 2 \), one has

\[ \nu_m = 5.8 \times 10^{15} \text{ Hz} \ \cong \ \frac{G(p)}{G(2.3)} E_{52}^{1/2} A_{13}^{1/2} n_{0,0}^{1/2} \zeta_0^{1/2} \epsilon_0^{1/2} \epsilon_{-1}^{1/2} B_{-2}^{1/2}, \]

\[ \nu_c = 1.2 \times 10^{14} \text{ Hz} \ \cong \ \zeta = 2^{1/2} E_{52}^{1/2} A_{13}^{1/2} n_{0,0}^{1/2} \zeta_0^{1/2} \epsilon_0^{1/2} \epsilon_{-1}^{1/2} B_{-2}^{1/2}, \]

\[ F_{\nu,\text{max}} = 5.0 \times 10^4 \text{ Jy} \ \cong \ \zeta = 5^{1/2} E_{52}^{1/2} A_{13}^{1/2} n_{0,0}^{1/2} \zeta_0^{1/2} \epsilon_0^{1/2} \epsilon_{-1}^{1/2} B_{-2}^{1/2}, \]

For \( 1 < p < 2 \), one has (\( \nu_c \) and \( F_{\nu,\text{max}} \) remain the same)

\[ \nu_m = 5.6 \times 10^{13} \text{ Hz} \ \cong \ \zeta = 2^{p-1} E_{52}^{p/1} A_{13}^{p/1} n_{0,0}^{p/1} \zeta_0^{p/1} \epsilon_0^{p/1} \epsilon_{-1}^{p/1} B_{-2}^{p/1}, \]

\[ \nu_c = 4.3 \times 10^{12} \text{ Hz} \ \cong \ \zeta = 2^{p-1} E_{52}^{p/1} A_{13}^{p/1} n_{0,0}^{p/1} \zeta_0^{p/1} \epsilon_0^{p/1} \epsilon_{-1}^{p/1} B_{-2}^{p/1}, \]

\[ \nu_m = 1.3 \times 10^{13} \text{ Hz} \ \cong \ \zeta = 2^{p-1} E_{52}^{p/1} A_{13}^{p/1} n_{0,0}^{p/1} \zeta_0^{p/1} \epsilon_0^{p/1} \epsilon_{-1}^{p/1} B_{-2}^{p/1}, \]

\[ \nu_c = 3.0 \times 10^{12} \text{ Hz} \ \cong \ \zeta = 2^{p-1} E_{52}^{p/1} A_{13}^{p/1} n_{0,0}^{p/1} \zeta_0^{p/1} \epsilon_0^{p/1} \epsilon_{-1}^{p/1} B_{-2}^{p/1}, \]

The \( \alpha \) and \( \beta \) values and their closure relations for the thick shell forward shock models are presented in Tables [7] and [8].
Table 7: The temporal decay index $\alpha$ and spectral index $\beta$ of the thick shell forward shock model in the $\nu_a < \min(\nu_m, \nu_c)$ spectral regime.

|        | $p > 2$ | $1 < p < 2$ |
|--------|---------|-------------|
| $\nu < \nu_a$ | $-2$   | $-1$        |
| $\nu_a < \nu < \nu_m$ | $-\frac{1}{3}$ | $-\frac{4}{3}$ |
| $\nu_m < \nu < \nu_c$ | $\frac{p-1}{2}$ | $\frac{p-3}{2}$ |
| $\nu > \nu_c$ | $\frac{p}{2}$ | $\frac{p-2}{2}$ |

**ISM** slow cooling

|        | $p > 2$ | $1 < p < 2$ |
|--------|---------|-------------|
| $\nu < \nu_a$ | $-2$   | $-1$        |
| $\nu_a < \nu < \nu_m$ | $-\frac{1}{3}$ | $-\frac{4}{3}$ |
| $\nu_m < \nu < \nu_c$ | $\frac{p-1}{2}$ | $\frac{p-3}{2}$ |
| $\nu > \nu_c$ | $\frac{p}{2}$ | $\frac{p-2}{2}$ |

**ISM** fast cooling

|        | $p > 2$ | $1 < p < 2$ |
|--------|---------|-------------|
| $\nu < \nu_a$ | $-2$   | $-1$        |
| $\nu_a < \nu < \nu_m$ | $-\frac{1}{3}$ | $-\frac{4}{3}$ |
| $\nu_m < \nu < \nu_c$ | $\frac{p-1}{2}$ | $\frac{p-3}{2}$ |
| $\nu > \nu_c$ | $\frac{p}{2}$ | $\frac{p-2}{2}$ |

**Wind** slow cooling

|        | $p > 2$ | $1 < p < 2$ |
|--------|---------|-------------|
| $\nu < \nu_a$ | $-2$   | $-1$        |
| $\nu_a < \nu < \nu_m$ | $-\frac{1}{3}$ | $-\frac{4}{3}$ |
| $\nu_m < \nu < \nu_c$ | $\frac{p-1}{2}$ | $\frac{p-3}{2}$ |
| $\nu > \nu_c$ | $\frac{p}{2}$ | $\frac{p-2}{2}$ |

**Wind** fast cooling

|        | $p > 2$ | $1 < p < 2$ |
|--------|---------|-------------|
| $\nu < \nu_a$ | $-2$   | $-1$        |
| $\nu_a < \nu < \nu_m$ | $-\frac{1}{3}$ | $-\frac{4}{3}$ |
| $\nu_m < \nu < \nu_c$ | $\frac{p-1}{2}$ | $\frac{p-3}{2}$ |
| $\nu > \nu_c$ | $\frac{p}{2}$ | $\frac{p-2}{2}$ |

For this regime (thick-shell forward shock model during shock crossing), for $p > 2$, one has $\nu_m \propto t^{-1} \left( t^{-1} \right)$, $\nu_c \propto t^{-1} \left( t^1 \right)$, $F_{\nu_{\max}} \propto t^0 \left( t^0 \right)$ for the ISM (wind) models, respectively. For $1 < p < 2$, $\nu_c$ and $F_{\nu_{\max}}$ evolutions are the same as $p > 2$ cases, while $\nu_m \propto t^{\frac{p+2}{(1-p)}} \left( t^{\frac{1}{1-p}} \right)$ for the ISM (wind) models, respectively.

3.1.4. **Thick Shell Reverse Shock Model**

Using the same dynamics in Eq. (35), one can characterize the reverse shock emission during the shock crossing phase.

For the ISM model and $p > 2$, the reverse shock emission can be chara-
Table 8: The temporal decay index $\alpha$ and spectral index $\beta$ of the thick shell forward shock model in the $\nu_m < \nu_a < \nu_c$ spectral regime.

| $\nu$         | $p > 2$ | $1 < p < 2$ |
|---------------|---------|-------------|
| ISM           | $\alpha$ | $\alpha(\beta)$ | $\alpha$ | $\alpha(\beta)$ |
| $\nu < \nu_a$ | $-2$     | $-1$        | $\alpha = \frac{2}{7}$ | $\frac{11p-11}{8(1-p)}$ |
| $\nu_a < \nu < \nu_m$ | $-\frac{3}{2}$ | $-\frac{3}{2}$ | $\alpha = \frac{9\beta}{2}$ | $-\frac{3}{2}$ |
| $\nu_m < \nu < \nu_c$ | $\frac{p-1}{2}$ | $\frac{p-3}{2}$ | $\alpha = \beta - 1$ | $\frac{p-6}{8}$ |
| $\nu > \nu_c$ | $-2$     | $\alpha = \beta - 1$ | $-2$ |

Wind cooling:

| $\nu$         | $p > 2$ | $1 < p < 2$ |
|---------------|---------|-------------|
| $\nu < \nu_a$ | $-2$     | $-2$        | $\alpha = \beta$ | $\frac{3p-6}{2(1-p)}$ |
| $\nu_a < \nu < \nu_m$ | $-\frac{3}{2}$ | $-\frac{3}{2}$ | $\alpha = \frac{15\beta}{2}$ | $-\frac{3}{2}$ |
| $\nu_m < \nu < \nu_c$ | $\frac{p-1}{2}$ | $\frac{p-3}{2}$ | $\alpha = \beta$ | $\frac{1}{2}$ |
| $\nu > \nu_c$ | $-2$     | $\alpha = \beta - 1$ | $0$ |

For $1 < p < 2$, one has ($\nu_c$ and $F_{v,\text{max}}$ remain the same)

$$
\nu_m = 7.6 \times 10^{11} \text{ Hz} \frac{\hat{G}(p)}{G(2.3)} \frac{\Gamma_0^2}{2.0} n_{0,0}^{1/2} \frac{E_{v_0}}{c^{1/2} B_{-2}},
$$

$$
\nu_c = 1.2 \times 10^{17} \text{ Hz} E_{52}^{-1/2} \Delta_{0.13}^{1/2} n_{0,0}^{-1/2} B_{-2}^{-1} D_{28}^{-1/2},
$$

$$
F_{v,\text{max}} = 1.3 \times 10^5 \mu\text{Jy} \frac{\hat{g}_f(p)}{\hat{g}_f(2.3)} E_{52}^{-1/2} \Delta_{0.13}^{1/2} n_{0,0}^{1/2} E_{B,-2}^{-1} D_{28}^{-1/2};
$$

$$
\nu_a = 7.2 \times 10^{12} \text{ Hz} \frac{\hat{g}_f(p)}{\hat{g}_f(2.3)} E_{52}^{7/4} \Delta_{0.13}^{5/4} n_{0,0}^{1/4} E_{B,-2}^{1/4} D_{28}^{-1/2};
$$

$$
\nu_a = 2.5 \times 10^{12} \text{ Hz} \frac{\hat{g}_f(p)}{\hat{g}_f(2.3)} E_{52}^{7/4} \Delta_{0.13}^{5/4} n_{0,0}^{1/4} E_{B,-2}^{1/4} D_{28}^{-1/2};
$$

$$
\nu_a = 1.8 \times 10^{10} \text{ Hz} \frac{\hat{g}_f(p)}{\hat{g}_f(2.3)} E_{52}^{17/20} \Delta_{0.13}^{17/20} n_{0,0}^{19/20} E_{B,-2}^{6/5} D_{28}^{-1/2};
$$

For $1 < p < 2$, one has ($\nu_c$ and $F_{v,\text{max}}$ remain the same)

$$
\nu_m = 6.1 \times 10^{8} \text{ Hz} \frac{\hat{g}_f(p)}{\hat{g}_f(1.8)} E_{52}^{8-6p} \Delta_{0.13}^{8-6p} n_{0,0}^{6-6p} E_{B,-2}^{7-6p} D_{28}^{8-6p};
$$

$$
\nu_a = 2.1 \times 10^{14} \text{ Hz} \frac{\hat{g}_f(p)}{\hat{g}_f(1.8)} E_{52}^{8-6p} \Delta_{0.13}^{8-6p} n_{0,0}^{6-6p} E_{B,-2}^{7-6p} D_{28}^{8-6p}.
\[ \nu_a = 9.3 \times 10^{11} \text{ Hz} \hat{\nu}^{3p+10}_{26} \frac{g^{VI}(p)}{g^{VI}(1.8)} E_{52}^{2p+6} A_{*,-1}^{p+4} \Delta_{0,13}^{p+14} \eta_{0,0}^{p-18} \epsilon_{e,-1}^{2p} e^{-2p} e^{-2p} \frac{1}{52(1-p)} \] , \quad \nu_a < \nu_m < \nu_c

\[ \nu_a = 1.5 \times 10^{10} \text{ Hz} \hat{\nu}^{-9/10} \frac{g^{VII}(p)}{g^{VII}(1.8)} E_{52}^{17/20} \Gamma_{0,2}^{-3/5} \Delta_{0,13}^{-17/20} \eta_{0,0}^{19/20} \epsilon_{B,-2}^{6/5} e^{-1/10} \] , \quad \nu_a < \nu_c < \nu_m

For the wind model and \( p > 2 \), one has

\[ \nu_m = 3.3 \times 10^{13} \text{ Hz} \frac{G(p)}{G(2.3)} E_{52}^{-1/2} A_{*,-1}^{1/2} \Gamma_{0,2}^{1/2} \Delta_{0,13}^{1/2} e_{e,-1}^{1/2} \epsilon_{B,-2}^{1/2} t_2 \] , \quad \nu_a < \nu_m < \nu_c

\[ \nu_c = 1.2 \times 10^{14} \text{ Hz} \hat{\nu}^{-2} E_{52}^{1/2} \Delta_{0,13}^{-1/2} A_{*,-1}^{2} \epsilon_{B,-2}^{2} \] \[ F_{\nu,\text{max}} = 6.7 \times 10^{5} \mu\text{Jy} \hat{\nu} E_{52} A_{*,-1}^{1/2} \Gamma_{0,2}^{-1} \Delta_{0,13}^{1/2} \epsilon_{e,-1}^{2} \epsilon_{B,-2}^{2} D_{28}^{2} \] , \quad \nu_a < \nu_m < \nu_c

\[ \nu_a = 3.2 \times 10^{13} \text{ Hz} \frac{g^{VIII}(p)}{g^{VIII}(2.3)} E_{52}^{2p-8/5} \Gamma_{0,2}^{1/2} A_{*,-1}^{2p} \Delta_{0,13}^{2p-1/5} \epsilon_{e,-1}^{1/5} \epsilon_{B,-2}^{1/5} t_2 \] , \quad \nu_a < \nu_m < \nu_c

\[ \nu_a = 3.3 \times 10^{13} \text{ Hz} \frac{g^{IX}(p)}{g^{IX}(2.3)} E_{52}^{2p} \Gamma_{0,2}^{2p} A_{*,-1}^{2p+2} \Delta_{0,13}^{2p+2} \epsilon_{e,-1}^{2p} \epsilon_{B,-2}^{2p} t_2 \] , \quad \nu_m < \nu_a < \nu_c

\[ \nu_a = 1.7 \times 10^{13} \text{ Hz} \hat{\nu}^{3p-6} \frac{g^{X}(p)}{g^{X}(2.3)} E_{52}^{-3/5} \Gamma_{0,2}^{1/10} A_{*,-1}^{19/10} \epsilon_{e,-1}^{6/5} \epsilon_{B,-2}^{1/10} t_2 \] , \quad \nu_a < \nu_c < \nu_m

For \( 1 < p < 2 \), one has (\( \nu_c \) and \( F_{\nu,\text{max}} \) remain the same)

\[ \nu_m = 8.7 \times 10^{10} \text{ Hz} \hat{\nu}^{2p} \frac{g^{XI}(p)}{g^{XI}(1.8)} E_{52}^{-2p} A_{*,-1}^{2p} \Delta_{0,13}^{2p} \epsilon_{e,-1}^{2p} \epsilon_{B,-2}^{2p} t_2 \] , \quad \nu_a < \nu_m < \nu_c

\[ \nu_a = 5.2 \times 10^{14} \text{ Hz} \hat{\nu}^{2p-2} \frac{g^{XII}(p)}{g^{XII}(1.8)} E_{52}^{2p+4} \Gamma_{0,2}^{p-2} A_{*,-1}^{2p+4} \Delta_{0,13}^{p-2} \epsilon_{e,-1}^{2p+4} \epsilon_{B,-2}^{p-2} \] , \quad \nu_a < \nu_m < \nu_c

\[ \nu_a = 1.3 \times 10^{13} \text{ Hz} \hat{\nu}^{2p+2} \frac{g^{XIII}(p)}{g^{XIII}(1.8)} E_{52}^{2p+4} \Delta_{0,13}^{2p+4} A_{*,-1}^{2p+4} \epsilon_{e,-1}^{2p+4} \epsilon_{B,-2}^{2p+4} t_2 \] , \quad \nu_m < \nu_a < \nu_c

\[ \nu_a = 1.4 \times 10^{13} \text{ Hz} \hat{\nu}^{2p} \frac{g^{XIV}(p)}{g^{XIV}(1.8)} E_{52}^{-1/10} \Gamma_{0,2}^{-3/5} A_{*,-1}^{19/10} \epsilon_{e,-1}^{6/5} \epsilon_{B,-2}^{-1/10} t_2 \] , \quad \nu_a < \nu_c < \nu_m

(43)
After the reverse shock crosses the shell, the shocked shell can be roughly described by the BM solution (Kobayashi and Sari, 2000; Wu et al., 2003; Kobayashi and Zhang, 2003a; Kobayashi et al., 2004),

\[\gamma_3 \propto t^{(2k-7)/4(4-k)}, \epsilon_3 \propto t^{(2k-13)/3(4-k)}, r \propto t^{1/(8-2k)}, N_{e,3} \propto t^0,\]  

(44)

For the ISM case, one has

\[p > \nu \Rightarrow \gamma = \gamma_{3,x} \left(\frac{t}{T}\right)^{-\frac{7}{16}}, \quad R = R_x \left(\frac{t}{T}\right)^{\frac{1}{8}}\]

where \(\gamma_{3,x}\) and \(R_x\) are the Lorentz factor and radius of Region 3 at the shock crossing time.

For \(p > 1\), one has

\[\nu_m = 4.8 \times 10^{12} \text{ Hz} \quad \gamma_{3,x} \left(\frac{t}{T}\right)^{-\frac{7}{16}}, \quad R = R_x \left(\frac{t}{T}\right)^{\frac{1}{8}}\]

\[\nu_{\text{cut}} = 2.3 \times 10^{17} \text{ Hz} \quad \gamma_{3,x} \left(\frac{t}{T}\right)^{-\frac{7}{16}}, \quad R = R_x \left(\frac{t}{T}\right)^{\frac{1}{8}}\]

\[F_{\nu_{\text{max}}} = 7.9 \times 10^5 \mu\text{Jy} \quad \gamma_{3,x} \left(\frac{t}{T}\right)^{-\frac{7}{16}}, \quad R = R_x \left(\frac{t}{T}\right)^{\frac{1}{8}}\]

(45)

For \(1 < p < 2\), one has (\(\nu_c\) and \(F_{\nu_{\text{max}}\text{max}}\) remain the same)

\[\nu_m = 4.2 \times 10^{12} \text{ Hz} \quad \gamma_{3,x} \left(\frac{t}{T}\right)^{-\frac{7}{16}}, \quad R = R_x \left(\frac{t}{T}\right)^{\frac{1}{8}}\]

\[\nu_{\text{cut}} = 2.3 \times 10^{17} \text{ Hz} \quad \gamma_{3,x} \left(\frac{t}{T}\right)^{-\frac{7}{16}}, \quad R = R_x \left(\frac{t}{T}\right)^{\frac{1}{8}}\]

\[F_{\nu_{\text{max}}} = 7.9 \times 10^5 \mu\text{Jy} \quad \gamma_{3,x} \left(\frac{t}{T}\right)^{-\frac{7}{16}}, \quad R = R_x \left(\frac{t}{T}\right)^{\frac{1}{8}}\]

(46)
\[ \nu_m = 9.4 \times 10^{13} \text{ Hz} \hat{z}^{7/8} \frac{G(p)}{G(2.3)} E^{1/2}_{52} A_{s,-1}^{1/2} \Delta^{11/8}_{0,13} e_{0,13}^{1/2} e_{B,-2}^{-1/2} \nu_{\text{cut}} = 3.7 \times 10^{15} \text{ Hz} \hat{z}^{7/8} E^{1/2}_{52} \Delta^{19/8}_{0,13} A_{s,-1}^{-1/2} e_{B,-2}^{-3/2} \nu_{\nu_{\text{max}}} = 2.6 \times 10^6 \mu \text{Jy} \hat{z}^{17/8} E^{1/2}_{52} A_{s,-1}^{1/2} \Delta^{11/8}_{0,13} e_{B,-2}^{-1/2} D_{28}^{-2} t_2^{-9/8}, \]

\[ \nu_a = 1.9 \times 10^{13} \text{ Hz} \hat{z}^{-2/5} \frac{g^{XXI}(p)}{g^{XXI}(2.3)} E^{2/5}_{52} \Delta^{-8/5}_{0,2} A_{s,-1}^{2/5} \Delta^{4/5}_{0,13} e_{0,13}^{1/5} e_{B,-2}^{-3/5}, \quad \nu_a < \nu_m < \nu_{\text{cut}} \]

\[ \nu_a = 4.1 \times 10^{13} \text{ Hz} \hat{z}^{2/5} \frac{g^{XXI}(p)}{g^{XXI}(2.3)} E^{2/5}_{52} \Delta^{-8/5}_{0,2} A_{s,-1}^{2/5} \Delta^{4/5}_{0,13} e_{0,13}^{1/5} e_{B,-2}^{-3/5}, \quad \nu_m < \nu_a < \nu_{\text{cut}} \] (47)

For \( 1 < p < 2 \), one has (\( \nu_c \) and \( \nu_{\nu_{\text{max}}} \) remain the same)

\[ \nu_m = 1.9 \times 10^{14} \text{ Hz} \hat{z}^{7/8} \frac{g^{XXII}(p)}{g^{XXII}(1.8)} E^{4/5}_{52} \Delta^{-2/5}_{0,2} A_{s,-1}^{6/5} \Delta^{1/5}_{0,13} \Delta^{13/15}_{0,13} e_{0,13}^{1/5} e_{B,-2}^{-15/8}, \]

\[ \nu_a = 1.2 \times 10^{13} \text{ Hz} \hat{z}^{-2/5} \frac{g^{XXIII}(p)}{g^{XXIII}(1.8)} E^{2/5}_{52} \Delta^{-8/5}_{0,2} A_{s,-1}^{2/5} \Delta^{4/5}_{0,13} \Delta^{13/15}_{0,13} e_{0,13}^{1/5} e_{B,-2}^{-15/8}, \quad \nu_a < \nu_m < \nu_{\text{cut}} \]

\[ \nu_a = 3.8 \times 10^{13} \text{ Hz} \hat{z}^{2/5} \frac{g^{XXIV}(p)}{g^{XXIV}(1.8)} E^{2/5}_{52} \Delta^{-8/5}_{0,2} A_{s,-1}^{2/5} \Delta^{4/5}_{0,13} \Delta^{13/15}_{0,13} e_{0,13}^{1/5} e_{B,-2}^{-15/8}, \quad \nu_m < \nu_a < \nu_{\text{cut}} \] (48)

The \( \alpha \) and \( \beta \) values and their closure relations for the thick shell reverse shock models are presented in Tables IX and X (for pre-shock-crossing), and Tables XI and XII (for post-shock-crossing).

For this regime (thick-shell reverse shock model during shock crossing), for \( p > 2 \), one has \( \nu_m \propto t^0 \) \( (t^{-1}) \), \( \nu_c \propto t^{-1} \) \( (t^1) \), \( \nu_{\nu_{\text{max}}} \propto t^{1/2} \) \( (t^0) \) for the ISM (wind) models, respectively. For \( 1 < p < 2 \), \( \nu_c \) and \( \nu_{\nu_{\text{max}}} \) evolutions are the same as \( p > 2 \) cases, while \( \nu_m \propto t^{2-p} \) \( (t^{-p}) \) for the ISM (wind) models, respectively.

After shock crossing, \( \nu_m \propto \nu_{\text{cut}} \propto t^{-73/48} \) \( (t^{-15/8}) \), \( \nu_{\nu_{\text{max}}} \propto t^{-47/48} \) \( (t^{-9/8}) \) for the ISM (wind) models, respectively.
Table 9: The temporal decay index \( \alpha \) and spectral index \( \beta \) of the thick shell reverse shock model during the shock crossing phase in the \( \nu_a < \min(\nu_m, \nu_c) \) spectral regime.

| \( \nu < \nu_a \) | \( p > 2 \) | \( 1 < p < 2 \) |
|-----------------|-------|-------|
| \( \nu_a < \nu < \nu_m \) | \( p-1 \) | \( \frac{p-6}{8} \) |
| \( \nu_m < \nu < \nu_c \) | \( p-2 \) | \( p-2 \) |

| \( \nu > \nu_c \) | \( -p \) | \( -p \) |

| \( \nu < \nu_a \) | \( -2 \) | \( -\frac{1}{2} \) |
| \( \nu_a < \nu < \nu_m \) | \( -\frac{1}{3} \) | \( -\frac{1}{6} \) |
| \( \nu_m < \nu < \nu_c \) | \( \frac{p-1}{2} \) | \( \frac{p-1}{2} \) |
| \( \nu > \nu_c \) | \( \frac{p}{2} \) | \( \frac{p}{2} \) |

Notice that in the above treatment, a relativistic reverse shock has been assumed. In reality, there is a brief epoch before the reverse shock becomes relativistic. There should be an additional dynamical change at \( R_N \) (the transition radius from Newtonian to relativistic reverse shock), which is much smaller than \( R_x \) \([\text{Sari and Piran, 1995}]\). The light curves may show an additional break at this epoch, before which the thin shell scalings discussed in §3.1.1 and §3.1.2 apply.
Table 10: The temporal decay index $\alpha$ and spectral index $\beta$ for the thick shell reverse shock model during the reverse shock crossing phase in the $\nu_m < \nu_a < \nu_c$ spectral regime.

3.2. Phase 2: Relativistic, pre-jet-break, self-similar deceleration phase

After reverse shock crosses the shell, the blastwave would quickly adjusts itself to a self-similar deceleration phase (Blandford and McKee, 1976). Early on, the blastwave is ultra-relativistic with $\frac{1}{\Gamma} \ll \theta_j$. The closure relations in this phase have been reviewed previously (e.g. Zhang and Mészáros, 2004; Zhang et al., 2006).

3.2.1. Adiabatic deceleration without energy injection

The simplest model invokes a constant energy in the blastwave. This requires that the blastwave is adiabatic (no radiative loss), and that there is no energy injection into the blastwave. The adiabatic approximation usually gives a reasonable description to the blastwave evolution. This is because the radiative loss fraction is at most $\epsilon_{e}$ (for fast cooling), which is constrained to be around 0.1 and lower (Panaitescu and Kumar, 2001, 2002; Yost et al., 2003).

---

4This is the case for the idealized situation. In reality, there might be irregularities in the system (e.g. ambient density fluctuations or non-power-law energy injection). The blastwave is no longer self-similar. We limit ourselves to the self-similar assumption and derive the scalings in this subsection, and discuss more complicated simulations in §5.

5Note that since the blast-wave energy is given again and again to newly heated material, the radiative energy loss may become important after several orders of magnitude of deceleration time (Sari, 1997).
For an arbitrary $k$ density profile, the dynamics of the blast wave in the constant energy regime can be described as

$$\gamma = \left(\frac{(17 - 4k)E}{4^{1-k}(4 - k)^{3-k} \pi \rho_0 c^{5-k} t^{3-k}}\right)^{1/3}, \quad R = \left(\frac{(17 - 4k)(4 - k)Et}{4\pi \rho_0 c}\right)^{1/3}.$$  

For the ISM model ($k = 0$) and $p > 2$, one has

$$\nu_m = 4.3 \times 10^{10} \text{ Hz } \tilde{z}^{1/2} \frac{G(p)}{G(2.3)} \frac{E^{1/2}}{E_{52}^{1/2}} \frac{\epsilon_{-1}^{1/2}}{\epsilon_{B,-2}^{1/2}} t_{5}^{-3/2},$$

$$\nu_c = 2.9 \times 10^{16} \text{ Hz } \tilde{z}^{-1/2} E_{52}^{-1/2} n_{0}^{-1} \epsilon_{B,-2}^{-1/2},$$

$$F_{\nu,\text{max}} = 1.1 \times 10^{4} \mu\text{Jy } \tilde{z} E_{52}^{-1/2} n_{0}^{-1/2} D_{28}^{-2},$$

$$\nu_a = 5.7 \times 10^{9} \text{ Hz } \tilde{z}^{-1} \frac{g^I(p)}{g^I(2.3)} E_{52}^{1/5} n_{0}^{5/6} \epsilon_{-1}^{3/5} \epsilon_{B,-2}^{-1/2}, \quad \nu_a < \nu_m < \nu_c,$$

$$\nu_a = 1.5 \times 10^{10} \text{ Hz } \tilde{z}^{\frac{p-6}{2(p+4)}} \frac{g^{II}(p)}{g^{II}(2.3)} E_{52}^{\frac{p+2}{2(p+4)}} n_{0}^{\frac{2-p}{2(p+4)}} \epsilon_{-1}^{\frac{1}{2(p+4)}} \epsilon_{B,-2}^{\frac{1}{2(p+4)}} t_{5}^{\frac{3p+2}{2(p+4)}}, \quad \nu_m < \nu_a < \nu_c,$$

$$\nu_a = 6.9 \times 10^{6} \text{ Hz } \tilde{z}^{-1/2} \frac{g^{III}(p)}{g^{III}(2.3)} E_{52}^{7/10} n_{0}^{11/10} \epsilon_{B,-2}^{-1/2} t_{5}^{-1/2}, \quad \nu_a < \nu_c < \nu_m$$

(49)

For $1 < p < 2$, one has ($\nu_c$ and $F_{\nu,\text{max}}$ remain the same)

$$\nu_m = 3.6 \times 10^{7} \text{ Hz } \tilde{z}^{\frac{14-5p}{2(p+1)}} \frac{g^{IV}(p)}{g^{IV}(1.8)} E_{52}^{\frac{p+2}{2(p+1)}} n_{0}^{\frac{2-p}{2(p+1)}} \epsilon_{-1}^{\frac{1}{2(p+1)}} \epsilon_{B,-2}^{\frac{3p+6}{2(p+1)}} t_{5}^{-1},$$

$$\nu_a = 1.6 \times 10^{11} \text{ Hz } \tilde{z}^{-\frac{7(p+2)}{16p(p-1)}} \frac{g^{V}(p)}{g^{V}(1.8)} E_{52}^{\frac{46-31p}{80(p-1)}} n_{0}^{\frac{58-53p}{80(p-1)}} \epsilon_{-1}^{\frac{1}{2(p-1)}} \epsilon_{B,-2}^{\frac{14-9p}{16(p-1)}} t_{5}^{-\frac{9p-5}{16(p-1)}}, \quad \nu_a < \nu_m < \nu_c,$$

$$\nu_a = 4.5 \times 10^{9} \text{ Hz } \tilde{z}^{-\frac{5p+6}{8(p+4)}} \frac{g^{VI}(p)}{g^{VI}(1.8)} E_{52}^{\frac{p+14}{8(p+4)}} n_{0}^{\frac{18-p}{8(p+4)}} \epsilon_{-1}^{\frac{2}{p+4}} \epsilon_{B}^{\frac{2}{2(p+4)}} t_{5}^{-\frac{3p+26}{8(p+4)}}, \quad \nu_m < \nu_a < \nu_c,$$

$$\nu_a = 5.7 \times 10^{6} \text{ Hz } \tilde{z}^{-1/2} \frac{g^{VII}(p)}{g^{VII}(1.8)} E_{52}^{7/10} n_{0}^{11/10} \epsilon_{B,-2}^{-1/2} t_{5}^{-1/2}, \quad \nu_a < \nu_c < \nu_m$$

(50)

For the wind model ($k = 2$) and $p > 2$, one has

$$\nu_m = 2.2 \times 10^{10} \text{ Hz } \tilde{z}^{1/2} \frac{G(p)}{G(2.3)} E_{52}^{\frac{2}{e_{-1}}} \epsilon_{B,-2}^{\frac{1}{2}} t_{5}^{-3/2},$$

32
\[ \nu_c = 1.8 \times 10^{18} \text{ Hz} \hat{z}^{-3/2} E_{52}^{1/2} A_{-1}^{-2} c_{-2}^{-3/2} t_5^{1/2} \]

\[ F_{\nu, \text{max}} = 1.5 \times 10^3 \text{ \( \mu \)Jy} \hat{z}^{3/2} E_{52}^{1/2} A_{-1}^{-1} c_{-2}^{-2} D_{28}^{-2} t_5^{-1/2} , \]

\[ \nu_a = 1.0 \times 10^9 \text{ Hz} \hat{z}^{-2/5} \frac{g^{\text{VIII}}(p)}{g^{\text{VIII}}(2.3)} E_{52}^{-2/5} A_{-1}^{6/5} e_{-1}^{1/5} c_{-2}^{-2} t_5^{-3/5} \]

\[ \nu_a = 4.4 \times 10^9 \text{ Hz} \hat{z}^{-2/5} \frac{g^{\text{IX}}(p)}{g^{\text{IX}}(2.3)} E_{52}^{-2/5} A_{-1}^{8/5} e_{-1}^{1/5} c_{-2}^{-2} t_5^{-3/5} \]

\[ \nu_a = 1.2 \times 10^5 \text{ Hz} \hat{z}^{3/5} \frac{g^{\text{X}}(p)}{g^{\text{X}}(2.3)} E_{52}^{-2/5} A_{-1}^{11/5} e_{-1}^{6/5} c_{-2}^{-2} t_5^{-8/5} \]

For \( 1 < p < 2 \), one has (\( \nu_c \) and \( F_{\nu, \text{max}} \) remain the same)

\[ \nu_m = 1.5 \times 10^7 \text{ Hz} \hat{z}^{8/3} \frac{g^{\text{XI}}(p)}{g^{\text{XI}}(1.8)} E_{52}^{(p-1)} A_{-1}^{(p-1)} \hat{z}^{2/3} c_{-2}^{2/3} e_{-1}^{2/3} t_5^{1/3} \]

\[ \nu_a = 3.3 \times 10^{10} \text{ Hz} \hat{z}^{-3} \frac{g^{\text{XII}}(p)}{g^{\text{XII}}(1.8)} E_{52}^{-1} A_{-1}^{-1} \hat{z}^{2} c_{-2}^{2} e_{-1}^{2} t_5^{3} \]

\[ \nu_a = 1.3 \times 10^9 \text{ Hz} \hat{z}^{-3} \frac{g^{\text{XII}}(p)}{g^{\text{XII}}(1.8)} E_{52}^{-1} A_{-1}^{-1} \hat{z}^{2} c_{-2}^{2} e_{-1}^{2} t_5^{3} \]

\[ \nu_a = 9.5 \times 10^4 \text{ Hz} \hat{z}^{3/5} \frac{g^{\text{XIV}}(p)}{g^{\text{XIV}}(1.8)} E_{52}^{-2/5} A_{-1}^{11/5} e_{-1}^{6/5} c_{-2}^{-2} t_5^{-8/5} \]

\[ \nu_a < \nu_c < \nu_m < \nu_c < \nu_m \]

The \( \alpha \) and \( \beta \) values and their closure relations of these models are presented in Tables 13 to 16.

For this model (adiabatic deceleration without energy injection), for \( p > 2 \), one has \( \nu_m \propto t^{-3/2} \) (\( t^{-3/2} \)), \( \nu_c \propto t^{-1/2} \) (\( t^{-1/2} \)), \( F_{\nu, \text{max}} \propto t^0 \) (\( t^{-1/2} \)) for the ISM (wind) models, respectively. For \( 1 < p < 2 \), \( \nu_c \) and \( F_{\nu, \text{max}} \) evolutions are the same as \( p > 2 \) cases, while \( \nu_m \propto t^{\frac{3p+6}{p-1}} \) (\( t^{\frac{p+4}{p-1}} \)) for the ISM (wind) models, respectively.

3.2.2. Adiabatic deceleration with energy injection

In some central engines models, such as the millisecond magnetar model (Dai and Lu, 1998; Zhang and Mészáros, 2001), significant energy injection into the blastwave is possible. Assume that the central engine has a power-law luminosity history \( L(t) = L_0 \left( \frac{t}{t_0} \right)^{-q} \), the injected energy is
\[ E_{\text{inj}} = \frac{\nu_0 \nu}{1 - q} t^{1 - q} \]. If the injected energy is in the form of a Poynting flux so that a reverse shock does not exist or is weak, one can approximately treat the blastwave as a system with continuous energy increase. The energy injection effect becomes significant when \( E_{\text{inj}} \gg E_{\text{imp}} \), where \( E_{\text{imp}} \) is the impulsively injected energy during the prompt emission phase (Zhang and Mészáros, 2001a). The dynamics of the system can be described by

\[
\gamma = \left( \frac{(17 - 4k) E}{4^3 - k(4 - k)^3 - k \pi A n_{\rho} c^{5 - k} t_q^{+2 - k}} \right)^{1/q}, \quad R = \left( \frac{(17 - 4k)(4 - k) E t^{2 - q}}{4 \pi A n_{\rho} c} \right)^{1/q}.
\]

There is an alternative type of energy injection, which does not involve a long lasting central engine, but rather invokes a Lorentz factor stratification of the ejecta (Rees and Mészáros, 1998; Sari and Mészáros, 2000), e.g.,

\[ M(> \gamma) \propto \gamma^{-s} \]  

(53)

As the blastwave decelerates, ejecta with lower \( \gamma \) gradually piles up onto the blastwave so that the energy of the blastwave is increased. Since energy is injected when \( \Gamma \sim \gamma \), the reverse shock is very weak, one can treat the blastwave as a system with continuous energy injection.

The two energy injection mechanisms can be considered equivalent when bridging the two injection parameter \( s \) and \( q \), i.e.,

\[
s = \frac{10 - 3k - 7q + 2kq}{2 + q - k}, \quad q = \frac{10 - 2s - 3k + ks}{7 + s - 2k}
\]  

(54)

for general density profile \( n_1 = A R^{-k} \). For the ISM model and wind model, it becomes \( s = \frac{10 - 7q}{2 + q} \), \( q = \frac{10 - 2s}{7 + s} \) and \( s = \frac{4 - 3q}{q} \), \( q = \frac{4}{3 + s} \) respectively (Zhang et al., 2006).

In the following, we derive all the expressions using the parameter \( q \). For the ISM model \( (k = 0) \) and \( p > 2 \), one has

\[
\nu_m = 1.37 \times 10^{18} \, \text{Hz} \quad E_{55}^{5/2} E_{52}^{3/2} E_{n_0,0}^{1/2} \epsilon_{e,1}^{1} \epsilon_{B,-2}^{-1} t^{-1 - q/2}, \\
\nu_c = 9.2 \times 10^{18} \, \text{Hz} \quad \tilde{E}_{52}^{1/2} E_{55}^{1/2} n_{B,2}^{3/2} \epsilon_{e,1}^{-1/2} t^{-1 - q/2}, \\
F_{\nu,\text{max}} = 1.1 \times 10^{4} \, \mu\text{Jy} \quad \tilde{E}_{55}^{5/2} E_{52}^{1/2} n_{0,0,0} \epsilon_{e,1}^{1} \epsilon_{B,-2}^{-1} D_{23}^{2} t^{-1 - q}, \\
\nu_a = 5.7 \times 10^{9} \, \text{Hz} \quad \tilde{E}_{52}^{5/2} E_{55}^{5/2} n_{0,0,0}^{3/2} \epsilon_{e,1}^{1} \epsilon_{B,-2}^{-1} t^{1/2} t^{1/2}, \\
\nu_a = 5.0 \times 10^{13} \, \text{Hz} \quad E_{52}^{2(p+1)+2} E_{55}^{2(p+1)+2} n_{0,0,0}^{2(p+1)+2} \epsilon_{e,1}^{2(p+1)+2} \epsilon_{B,-2}^{2(p+1)+2} t^{-1/2} t^{1/2},
\]

\( \nu_a < \nu_m < \nu_c \)

(55)

\( \nu_a < \nu_a < \nu_c \)
\[ \nu_a = 2.2 \times 10^9 \text{ Hz} \; \tilde{z}^{7/10} \frac{g^{III}(p)}{g^{III}(2.3)} E^{7/10} \frac{n_0,0}{n_0} \frac{11/10}{10} \frac{6}{5} \frac{t^{-2}}{10}, \quad \nu_a < \nu_c < \nu_m \] (55)

For \( 1 < p < 2 \), one has \( \nu_c \) and \( F_{\nu, \text{max}} \) remain the same

\[ \nu_m = 2.9 \times 10^{16} \text{ Hz} \; \tilde{z}^{7/10} \frac{g^{V}(p)}{g^{V}(1.8)} E_5^{1/2} \frac{n_0,0}{n_0} \frac{2-p}{8} \frac{2}{0} \frac{1}{0}, \quad \nu_c = 3.2 \times 10^{10} \text{ Hz} \; \tilde{z}^{7/10} \frac{g^{VI}(p)}{g^{VI}(1.8)} E_5^{1/2} \frac{n_0,0}{n_0} \frac{2-p}{8} \frac{2}{0} \frac{1}{0}, \quad \nu_m < \nu_c < \nu_a \] (56)

For the wind model \( (k = 2) \) and \( p > 2 \), one has

\[ \nu_m = 7.0 \times 10^{17} \text{ Hz} \; \tilde{z}^{2} \frac{g^{VII}(p)}{g^{VII}(2.3)} E_5^{1/2} \frac{n_0,0}{n_0} \frac{2-p}{8} \frac{2}{0} \frac{1}{0}, \quad \nu_c = 5.8 \times 10^{15} \text{ Hz} \; \tilde{z}^{2} \frac{g^{VIII}(p)}{g^{VIII}(2.3)} E_5^{1/2} \frac{n_0,0}{n_0} \frac{2-p}{8} \frac{2}{0} \frac{1}{0}, \quad \nu_a = 1.0 \times 10^{12} \text{ Hz} \; \tilde{z}^{2} \frac{g^{IX}(p)}{g^{IX}(2.3)} E_5^{1/2} \frac{n_0,0}{n_0} \frac{2-p}{8} \frac{2}{0} \frac{1}{0}, \quad \nu_m < \nu_c < \nu_a \] (57)

For \( 1 < p < 2 \), one has \( \nu_c \) and \( F_{\nu, \text{max}} \) remain the same

\[ \nu_m = 1.7 \times 10^{16} \text{ Hz} \; \tilde{z}^{2} \frac{g^{XI}(p)}{g^{XI}(1.8)} E_5^{1/2} \frac{n_0,0}{n_0} \frac{2-p}{8} \frac{2}{0} \frac{1}{0}, \quad \nu_c = 5.5 \times 10^{12} \text{ Hz} \; \tilde{z}^{2} \frac{g^{XII}(p)}{g^{XII}(1.8)} E_5^{1/2} \frac{n_0,0}{n_0} \frac{2-p}{8} \frac{2}{0} \frac{1}{0}, \quad \nu_m < \nu_c < \nu_a \]
\[ \nu_a = 1.7 \times 10^{14} \text{ Hz} \frac{\gamma^{XIII}(p)}{g^{XIII}(1.8)} E_\frac{52}{52}^{p-2} A_\frac{52}{52}^{18-p} \frac{2}{2} \zeta_0^p \frac{2}{2} \epsilon_{e-1}^p \frac{2}{2} B_{-2}^t (\frac{p-2}{4p+4})^4, \]
\[ \nu_m < \nu_a < \nu_c \]
\[ \nu_a = 9.5 \times 10^{12} \text{ Hz} \frac{\gamma^{XIV}(p)}{g^{XIV}(1.8)} E_\frac{52}{52}^{2/5} A_\frac{52}{52}^{11/5} \frac{6/5}{6/5} \epsilon_{B-2}^t 2a/5-2, \]
\[ \nu_m < \nu_a < \nu_c \]
\[ \nu_a < \nu_c < \nu_m \]  

(58)

The \( \alpha \) and \( \beta \) values and their closure relations for these models are also presented in Tables 13 to 16.

For this model (adiabatic deceleration without energy injection), for \( p > 2 \), one has \( \nu_m \propto t^{1-q}/2 (t^{1-q}/2) \), \( \nu_c \propto t^{1-q}/2 (t^{1-q}/2) \), \( F_{\nu,\text{max}} \propto t^{1-q}/2 (t^{1-q}/2) \) for the ISM (wind) models, respectively. For \( 1 < p < 2 \), \( \nu_c \) and \( F_{\nu,\text{max}} \) evolutions are the same as \( p > 2 \) cases, while \( \nu_m \propto t^{(g+2)\theta_j^2/(4(1-p))} (t^{4(1-p)}) \) for the ISM (wind) models, respectively.

3.3. Phase 3: Post Jet Break Phase

The above calculations are based on the assumption of a spherical expansion. However, achromatic breaks seen in many afterglow lightcurves suggest that GRB outflows are collimated. For a simplified conical jet model with an opening angle \( \theta_j \), the jet effect becomes important when \( 1/\Gamma > \theta_j \). The lightcurve shows a steepening break around this time.

In the literature, two effects have been discussed to steepen the lightcurve. The first is the pure edge effect (e.g. Panaitescu et al., 1998). Since an observer sees emission within the \( 1/\Gamma \) cone for a blastwave moving with bulk Lorentz factor \( \Gamma \), he/she would feel the deficit of flux outside the \( \theta_j \) cone when \( 1/\Gamma > \theta_j \) is satisfied. Assuming that the dynamics does not change, the flux reduction factor would be \( \theta_j^2/(1/\Gamma)^2 = \Gamma^2 \theta_j^2 \). This defines the degree of steepening at the jet break.

The second effect discussed in the literature is the sideways expansion effect. According to (Rhoads, 1992; Sari et al., 1999), when \( \Gamma \sim \theta_j^{-1} \) is satisfied, sound waves in the jet would cross the jet in the transverse direction and lead to its sideways expansion. This leads to an exponentially deceleration of the jet. However, later numerical simulations, and more sophisticated analytical treatments suggest that sideways expansion is not important until \( \Gamma \) drops below a few (Kumar and Panaitescu, 2003; Cannizzo et al., 2004; Zhang and MacFadyen, 2009; Granot and Piran, 2012). We therefore do not discuss this effect.
Table 13: The temporal decay index $\alpha$ and spectral index $\beta$ in relativistic, isotropic, self-similar deceleration phase for $\nu_a < \min(\nu_m, \nu_c)$ and $p > 2$.

| ISM | slow cooling | \begin{tabular}{c|c|c|c|c} \hline \beta & no injection & \alpha \beta & injection & \alpha \beta \\ \hline \nu < \nu_a & -2 & -1 & $\alpha = \frac{\beta}{2}$ & $q - 1$ & \hline \nu_a < \nu < \nu_m & -1 & -1 & $\alpha = \frac{3\beta}{6}$ & $\frac{q}{5} - 8$ & \hline \nu_m < \nu < \nu_c & $p\frac{-1}{2}$ & $3(p-1)$ & $\alpha = \frac{2}{2}$ & $\frac{(2p-6)+(p+3)q}{6}$ & $\alpha = (q - 1) + \frac{(2+q)\beta}{2}$ \\ \nu > \nu_c & $p\frac{1}{2}$ & $3(p-2)$ & $\alpha = \frac{3\beta-1}{2}$ & $\frac{(2p-4)+(p+2)q}{4}$ & $\alpha = \frac{q-2}{2} + \frac{(2+q)\beta}{2}$ \\ \hline Wind | slow cooling | \begin{tabular}{c|c|c|c|c} \hline \beta & no injection & \alpha \beta & injection & \alpha \beta \\ \hline \nu < \nu_a & -2 & -1 & $\alpha = \frac{\beta}{2}$ & $q - 2$ & \hline \nu_a < \nu < \nu_m & -1 & 0 & $\alpha = \frac{3\beta}{6}$ & $\frac{q}{5} - 2$ & \hline \nu_m < \nu < \nu_c & $p\frac{1}{2}$ & $3(p-1)$ & $\alpha = \frac{3\beta+1}{2}$ & $\frac{(2p-2)+(p+1)q}{6}$ & $\alpha = \frac{q}{2} + \frac{(2+q)\beta}{2}$ \\ \nu > \nu_c & $p\frac{1}{2}$ & $3(p-2)$ & $\alpha = \frac{3\beta-1}{2}$ & $\frac{(2p-4)+(p+2)q}{4}$ & $\alpha = \frac{q-2}{2} + \frac{(2+q)\beta}{2}$ \\ \hline Wind | fast cooling | \begin{tabular}{c|c|c|c|c} \hline \beta & no injection & \alpha \beta & injection & \alpha \beta \\ \hline \nu < \nu_a & -2 & -2 & $\alpha = \beta$ & $q - 3$ & \hline \nu_a < \nu < \nu_c & -1 & 2 & $\alpha = -2\beta$ & $\frac{(1+q)}{6}$ & \hline \nu_m < \nu < \nu_c & $p\frac{1}{2}$ & $3(p-1)$ & $\alpha = \frac{3\beta+1}{2}$ & $\frac{(2p-2)+(p+1)q}{6}$ & $\alpha = \frac{q}{2} + \frac{(2+q)\beta}{2}$ \\ \nu > \nu_c & $p\frac{1}{2}$ & $3(p-2)$ & $\alpha = \frac{3\beta-1}{2}$ & $\frac{(2p-4)+(p+2)q}{4}$ & $\alpha = \frac{q-2}{2} + \frac{(2+q)\beta}{2}$ \\ \hline \end{tabular}
Table 14: The temporal decay index $\alpha$ and spectral index $\beta$ in relativistic, isotropic, self-similar deceleration phase for $\nu_m < \nu_a < \nu_c$ and $p > 2$.

| ISM        | Slow cooling | no injection | injection |
|------------|--------------|--------------|-----------|
| $\nu < \nu_m$ | $-2$   | $-\frac{1}{2}$ | $\alpha = \frac{2}{3}$ |
| $\nu_m < \nu < \nu_a$ | $-\frac{5}{2}$ | $-\frac{3}{4}$ | $\frac{3}{2}$ |
| $\nu_a < \nu < \nu_c$ | $\frac{p-1}{2}$ | $\frac{3(p+1)}{4}$ | $\alpha = \frac{3}{2}$ |
| $\nu > \nu_c$ | $\frac{p}{2}$ | $\frac{3p-2}{4}$ | $\alpha = \frac{3p-1}{2}$ |

For the edge effect only, in the post-jet-break phase the expressions of the break frequencies $\nu_a$, $\nu_m$, and $\nu_c$ and the peak flux density $F_{\nu,\text{max}}$ all remain the same as the isotropic phase. The temporal decay indices are changed with the extra steepening correction factor. In rare cases, continuous energy injection may extend to the post-jet-break phase. For completeness, we also discuss these cases. After shock crossing, the reverse shocked region decelerates with a different dynamics from the forward shocked region. Given a same jet opening angle, it corresponds to an earlier jet break time. In Table 17, we present the expressions of jet break time and the temporal indices changes ($\Delta \alpha$ defined as post-jet-break $\alpha_2$ minus pre-jet-break $\alpha_1$) for all the models in different regimes.

In Tables 18 and 19, we present $\alpha$ and $\beta$ values and their closure relations for the jet model. Since the reverse shock jet break is usually undetectable, only forward shock models are presented.

3.4. Phase 4: Newtonian Phase

The blastwave eventually enters the Newtonian phase when it has swept up a CBM mass comparable to the initial mass entrained in the ejecta. In the deep Newtonian phase, the dynamics is described by the well known
Table 15: The temporal decay index $\alpha$ and spectral index $\beta$ in relativistic, isotropic, self-similar deceleration phase for $\nu_a < \min(\nu_m, \nu_c)$ and $1 < p < 2$.

Sedov-Taylor solution:

\[
R = \left( \frac{5 - k}{2} \right)^{\frac{3}{2-k}} \left( \frac{(3-k)E}{2\pi Am_p} \right)^{\frac{1}{2-k}} t^{\frac{2}{2-k}}, \quad v = \left( \frac{5 - k}{2} \right)^{\frac{3}{2-k}} \left( \frac{(3-k)E}{2\pi Am_p} \right)^{\frac{1}{2-k}} t^{\frac{k-3}{2-k}} \tag{59}
\]

This phase has been studied extensively in the literature \cite{Wijers97, Dai99, Huang99, Huang00, Livio00, Huang03}.

In this phase, for an ISM medium and \( p > 2 \), one has

\[
\nu_m = 2.0 \times 10^{14} \text{ Hz } \hat{z}^{2} \frac{G(p)}{G(2.3)} E_5 n_{0,0}^{-1/2} \epsilon_{e,-1}^{-1/2} \epsilon_{B,-2}^{-3}, \quad \nu_c = 7.0 \times 10^{15} \text{ Hz } \hat{z}^{-4/5} E_5^{-3/5} n_{0,0}^{-9/10} \epsilon_{B,-2}^{-3/5},
\]

\[
F_{\nu,\text{max}} = 2.3 \times 10^2 \mu\text{Jy } \hat{z}^{2/5} E_5^{4/5} n_{0,0}^{7/10} \epsilon_{B,-2} D_2^{-2} t_5^{3/5};
\]

\[
\nu_a = 1.4 \times 10^7 \text{ Hz } \hat{z}^{-11/5} \frac{g_I(p)}{g_I(2.3)} E_5^{-1/5} n_{0,0,0}^{-1} \epsilon_{e,-1}^{-1/5} \epsilon_{B,-2}^{6/5}, \quad \nu_a < \nu_m < \nu_c
\]

\[
\nu_a = 3.3 \times 10^{10} \text{ Hz } \hat{z}^{2p-6} \frac{g^I(p)}{g_I(2.3)} E_5^{p} n_{0,0,0}^{6-p} \epsilon_{e,-1}^{3-p} \epsilon_{B,-2}^{2p+4} t_5^{-3p-2}, \quad \nu_m < \nu_a < \nu_c
\]

For \( 1 < p < 2 \), one has \((\nu_c \text{ and } F_{\nu,\text{max}} \text{ remain the same})\)

\[
\nu_m = 1.9 \times 10^{12} \text{ Hz } \hat{z}^{-4/3} \frac{g^{III}(p)}{g^{III}(1.8)} E_5^{1/3} n_{0,0,0}^{-1/3} \epsilon_{e,-1}^{2-p} \epsilon_{B,-2}^{2-p+1} t_5^{-p-1},
\]

\[
\nu_a = 1.2 \times 10^8 \text{ Hz } \hat{z}^{7p-8} \frac{g^IV(p)}{g^IV(1.8)} E_5^{3p-2} n_{0,0,0}^{2} \epsilon_{e,-1}^{4-p} \epsilon_{B,-2}^{2p-2} t_5^{-3p+4}, \quad \nu_a < \nu_m < \nu_c
\]

\[
\nu_a = 7.4 \times 10^9 \text{ Hz } \hat{z}^{-p} \frac{g^V(p)}{g^V(1.8)} E_5^{2} n_{0,0,0}^{2} \epsilon_{e,-1}^{2-p} \epsilon_{B,-2}^{2-p+4} t_5^{-p+4}, \quad \nu_m < \nu_a < \nu_c
\]

For the wind model and \( p > 2 \), one has

\[
\nu_m = 1.6 \times 10^{14} \text{ Hz } \hat{z}^{4/3} \frac{G(p)}{G(2.3)} E_5^{4/3} A_{*,1}^{-5/6} \epsilon_{e,-1}^{-1} \epsilon_{B,-2}^{-7/3} t_5^{-1/3},
\]

\[
\nu_c = 1.7 \times 10^{15} \text{ Hz } \hat{z}^{-2} A_{*,1}^{3/2} \epsilon_{B,-2}^{3/2} t_5
\]

\[
F_{\nu,\text{max}} = 5.3 \times 10^2 \mu\text{Jy } \hat{z}^{4/3} E_5^{1/3} A_{*,1}^{7/6} \epsilon_{B,-2}^{-1/2} D_2^{2} t_5^{-1/3};
\]

43
\[ \nu_a = 6.9 \times 10^7 \text{ Hz } \hat{z}^{-13/15} \frac{g^{VI}(p)}{g^{VII}(2.3)} E^{-3/15}_{52} A_{s,-1}^{5/3} \epsilon_{e,-1}^{2/5} \epsilon_{B,-2}^{2/5}, \quad \nu_a < \nu_m < \nu_c \]

\[ \nu_a = 6.9 \times 10^{10} \text{ Hz } \hat{z}^{-3(p+4)} \frac{g^{VI}(p)}{g^{VII}(2.3)} E^{-2(2p-3)}_{52} A_{s,-1}^{5(6-p)} \epsilon_{e,-1}^{2(p-1)} \epsilon_{B,-2}^{2(p+4)} \hat{t}_5^{2(p+4)}, \quad \nu_m < \nu_a < \nu_c \]

For \(1 < p < 2\), one has \((\nu_c \text{ and } F_{\nu,\text{max}} \text{ remain the same})\)

\[ \nu_m = 1.4 \times 10^{12} \text{ Hz } \hat{z}^{10-3p} \frac{g^{VIII}(p)}{g^{VIII}(1.8)} E^{4(p-1)}_{52} A_{s,-1}^{6(1-p)} \epsilon_{e,-1}^{p-1} \epsilon_{B,-2}^{2(p-1)} \hat{t}_5^{20(p-1)}, \quad \nu_a < \nu_m < \nu_c \]

\[ \nu_a = 6.0 \times 10^8 \text{ Hz } \hat{z}^{\frac{q-p}{3p(p-1)}} \frac{g^{IX}(p)}{g^{IX}(1.8)} E^{-3(p-1)}_{52} A_{s,-1}^{\frac{5(3p-2)}{12(p-1)}} \epsilon_{e,-1}^{\frac{p-2}{p-1}} \epsilon_{e,-1}^{\frac{14-9p}{15p(p-1)}} \epsilon_{e,-1}^{\frac{74-39p}{80(p-1)}}, \quad \nu_a < \nu_m < \nu_c \]

\[ \nu_a = 1.6 \times 10^{10} \text{ Hz } \hat{z}^{\frac{8-3p}{5p+4}} \frac{g^{IX}(p)}{g^{IX}(1.8)} E^{\frac{2}{3(p+4)}}_{52} A_{s,-1}^{\frac{10}{3(p+4)}} \epsilon_{e,-1}^{\frac{2-p}{p+4}} \epsilon_{e,-1}^{\frac{2}{p+4}} \epsilon_{B,-2}^{2\hat{t}_5^{20(p+4)}}, \quad \nu_m < \nu_a < \nu_c \]

The \(\alpha\) and \(\beta\) values and their closure relations in this phase are presented in Tables 20 and 21.

For this model (Newtonian Phase), for \(p > 2\), one has \(\nu_m \propto t^{-3} \left(t^{-7/3}\right)\), \(\nu_c \propto t^{-1/5} \left(t^1\right)\), \(F_{\nu,\text{max}} \propto t^{3/5} \left(t^{-1/3}\right)\) for the ISM (wind) models, respectively. For \(1 < p < 2\), \(\nu_c\) and \(F_{\nu,\text{max}}\) evolutions are the same as \(p > 2\) cases, while \(\nu_m \propto t^{1-p} \left(t^{3(1-p)}\right)\) for the ISM (wind) models, respectively.

### 4. Applications of the models

Section 3 gives a complete reference of all the possible analytical synchrotron external shock models. There are two opposite ways of applying this reference tool. First, one can fit the observational data to get both temporal decay index \(\alpha\) and spectral index \(\beta\), and then identify which spectral regime the observational frequency lies in. One can then constrain related afterglow parameters. To fully determine the parameters, one needs multi-wavelength, multi-epoch observational data. In any case, for the relativistic deceleration phase before the jet break, from which most data are collected, usually a closure relation study could give a quick judgement about the possible spectral regime and medium type. Alternatively, one can start to assign reasonable ranges of a set of model parameters, and apply the models to draw predicted light curves. By varying parameters, one can use the model to fit the observational data.
Table 20: The temporal decay index $\alpha$ and spectral index $\beta$ in the Newtonian phase for $\nu_a < \min(\nu_m, \nu_c)$.

| $\beta$ | no injection | injection | injection |
|---------|--------------|-----------|-----------|
| $\nu < \nu_a$ | $-2$ | $\frac{2}{5}$ | $\alpha = \frac{\beta}{5}$ | $\frac{26-11p}{10(p-1)}$ |
| $\nu_a < \nu < \nu_m$ | $-\frac{1}{3}$ | $-\frac{8}{5}$ | $\alpha = \frac{24\beta}{5}$ | $\frac{-3p}{3(p-2)}$ |
| $\nu_m < \nu < \nu_c$ | $p^{-1}$ | $\frac{3(5p-7)}{2}$ | $\alpha = \frac{3(5\beta-1)}{5}$ | $\frac{9}{10}$ |
| $\nu > \nu_c$ | $\frac{p}{2}$ | $\frac{3p^{-1}}{2}$ | $\alpha = 3\beta - 2$ | $1$ |

Table 21: The temporal decay index $\alpha$ and spectral index $\beta$ in the Newtonian phase for $\nu_m < \nu_a < \nu_c$.

| $\beta$ | no injection | injection | injection |
|---------|--------------|-----------|-----------|
| $\nu < \nu_m$ | $-2$ | $\frac{2}{5}$ | $\alpha = \frac{\beta}{5}$ | $\frac{26-11p}{10(p-1)}$ |
| $\nu_m < \nu < \nu_a$ | $-\frac{1}{3}$ | $-\frac{11}{10}$ | $\alpha = \frac{33\beta}{10}$ | $\frac{9}{10}$ |
| $\nu_a < \nu < \nu_c$ | $p^{-1}$ | $\frac{3(5p-7)}{2}$ | $\alpha = \frac{3(5\beta-1)}{5}$ | $\frac{9}{10}$ |
| $\nu > \nu_c$ | $\frac{p}{2}$ | $\frac{3p^{-1}}{2}$ | $\alpha = 3\beta - 2$ | $1$ |

45
Since the three characteristic frequencies $\nu_a$, $\nu_m$, and $\nu_c$ all evolve with time, the order among them may change during the evolution. The characteristic frequencies may also pass the observed band, so that the observational spectral regime may also change. These factors introduce complications in drawing theoretical lightcurves. First, one needs to estimate how spectral regimes evolve with time, using the related expressions of the characteristic frequencies; Second, one needs to use the closure relation tables to find out the temporal decay index for each segment of the light curve, and then connect all the segments. Lightcurves can differ for different dynamical models, different initial ordering of the characteristic frequencies, and different spectral regimes.

In order to make readers more conveniently use this reference tool, we plot all the possible lightcurve shapes that can be derived analytically and present spectral and temporal indices for each temporal segment for all the phases discussed in Section 3. These are presented in Figures 1 to 4. Some of these lightcurves may demand extreme afterglow parameters. However, since we aim at a complete reference of the models and keep a wide open range of the observational frequency and model parameters, we have included all the possible frequency regime transitions for all the phases. In reality, one could use the observational data to narrow down the possibilities to identify the most relevant lightcurve segments. For easy identification, Table 21 summarizes the corresponding figure numbers for different dynamical models and spectral regimes.

It is worth emphasizing that a critical time to separate Phase 1 (reverse shock crossing phase) and Phase 2 (self-similar deceleration phase) is the shock crossing time $t_x$ (Eq.20). At $t_x$, the ratios of the forward and reverse shock quantities $F_{\nu_{\text{max}}}$, $\nu_m$, $\nu_c$ etc. can be coasted into some simple forms (Zhang et al., 2003). Practically, one can derive the forward shock scaling first (which is easier), and extrapolate to $t_x$. Then applying

---

6The only spectral regimes that are not included are all the spectral orders that invoke $\nu_a > \nu_c$. For such combinations, the power-law description of electron energy distribution is no longer valid, and pile up of electrons near $\gamma_a$ is expected (Kobayashi et al., 2004; Gao et al., 2013). Since the exact shape of electron distribution cannot be obtained analytically, we do not include these cases in the figures. Such electron pile-up condition is usually not satisfied in most models reviewed in this paper. The only relevant model is the reverse shock model during the shock crossing phase for a wind medium, when $A_*$ is large enough (Kobayashi et al., 2004; Gao et al., 2013).
the reverse-to-forward shock ratios of critical parameters (Zhang et al., 2003; Harrison and Kobayashi, 2013), one can derive the reverse shock parameters at $t_x$. One can then apply the reverse shock scaling laws to derive reverse shock quantities. This approach would also lead to the same expressions derived in §3.1.2 and §3.1.4. By comparing the reverse-to-forward shock flux ratio at $t_x$, one can determine which component dominates for a specific frequency, see Figure 45 for example.

The numerous possible lightcurves in each phase make it impossible to draw all possible overall lightcurves. We therefore only draw a set of example lightcurves based on a standard set of parameters. In Figure 45, we present the “standard” afterglow light curves in radio ($10^9$ Hz), optical ($10^{15}$ Hz) and X-ray ($10^{17}$ Hz) bands, by adopting a set of typical parameter values: the total energy $E \sim 10^{52}$ erg, initial Lorentz factor $\Gamma_0 = 100$, width of ejecta $\Delta_0 = 10^{12}$ cm, jet opening angle $\theta_j = 0.1$, microphysics shock parameters $\epsilon_e = 0.1$, $\epsilon_B = 0.01$ and electron index $p = 2.3$ for both forward and reverse shocks. For the ISM model, we take $n_0 = 1$ cm$^{-3}$, so that the reverse shock is non-relativistic and the system is in the thin-shell approximation. For the wind model, we take $A_r = 0.1$, the reverse shock is relativistic and the system is in the thick-shell approximation. More detailed studies on the standard models can be found in the literature (e.g. Sari et al., 1998; Chevalier and Li, 2000; Granot and Sari, 2002; Wu et al., 2003; Kobayashi and Zhang, 2003a; Zou et al., 2005).

Several remarks regarding Fig.45 are worth addressing. 1. Only external shock afterglow light curves are plotted. If one includes the internal-origin “prompt” emission also, one would expect another component before $t_x$. There has been no observations in the radio band in this time frame. In the optical and X-ray band, this component is usually brighter than the external shock component, and hence, would mask the early phase of the lightcurves. After the cessation of the prompt emission, the lightcurve usually transits to the afterglow emission through a “steep decay” likely due to the high-latitude emission (e.g. as observed in the early X-ray afterglow detected with Swift, Tagliaferri et al., 2005; Zhang et al., 2006, 2007). 2. The lightcurves are plotted with identical microphysics parameters $\epsilon_e$ and $\epsilon_B$ in the forward and reverse shocks. For the particular set of parameters adopted, the reverse shock flux is usually lower than that of forward shock in both radio and X-ray band, and it only dominates the forward shock emission in the optical band early on for a brief time. Observational data, on the other hand, require different microphysics parameters in the two shocks, in particular,
a more magnetized reverse shock than the forward shock (Fan et al., 2002; Zhang et al., 2003; Kumar and Panaitescu, 2003; Harrison and Kobayashi, 2013). This corresponds to the ISM models with enhanced reverse shock peaks in the optical and radio bands. Specifically, in the radio lightcurve (top-left panel), the reverse shock flux at $t_{a+}$ is much brighter than the forward shock flux; in the optical band (mid-left panel), the reverse shock flux at $t_x$ way exceeds the forward shock flux, and even at $t_{m+}$ the reverse shock flux is higher than that of forward shock, so that the optical flux shows a “flattening” behavior (Zhang et al., 2003). These are the “radio flares” and “optical flashes” as observed in some GRBs, such as GRB 990123 (Akerlof et al., 1999; Kulkarni et al., 1999; Kobayashi and Sari, 2000). 3. Combining light curve features and spectral properties is essential to diagnose the physical origins of the afterglow emission. For example, the peaks of the light curves could be due to a hydro-dynamical origin (shock crossing or jet break) or crossing of a spectral break ($\nu_m$ or $\nu_a$). The former should not be accompanied by a color change while the latter should. Taking spectral observations before and after a certain break time is therefore crucial to identify the correct model to interpret the data. The hydrodynamical breaks are also expected to be “achromatic”, i.e. occurring in all wavelengths, while the frequency crossing breaks should be chromatic. So simultaneous observations in all wavelengths are also important to diagnose the physics of afterglow emission. 4. Some light curve properties can be quickly applied to diagnose the properties of the ambient medium. For example, in the pre-jet-break phase, the wind model has a steeper slope than the ISM model. In the optical band, a fast-rising optical flash would point towards an ISM origin. In the radio band, a forward shock peak due to jet break (achromatic break with other bands such as optical) would point towards an ISM origin.

5. Limitations of the analytical models

Despite their great success, the analytical synchrotron external shock models are known to have certain limitations that hinder a precise description of GRB afterglows. In many situations, numerical calculations are needed. In this section we itemize all the limitations of the analytical approach, which serve as a caution to readers to apply the analytical models reviewed in this paper.

- Swift observations suggest that X-ray flares observed in the afterglow phase can be best modeled as internal emission of late central engine
activities (Burrows et al., 2005; Zhang et al., 2006; Fan and Wei, 2005; Ioka et al., 2005; Lazzati and Perna, 2007; Maxham and Zhang, 2009). It is likely that some X-ray plateaus followed by steep decays (internal plateaus) are also caused by late central engine activities (Troja et al., 2007; Liang et al., 2007; Lyons et al., 2010). A more extreme view interprets all the X-ray afterglow as emission from the central engine (Ghisellini et al., 2007; Kumar et al., 2008b,a). Therefore the external shock model discussed in this review is not relevant to interpret X-ray flares and internal X-ray plateaus, and possibly even the entire X-ray emission.

• A relativistic ejecta moving towards the observer has a complicated equal arrival time effect (Waxman, 1997a; Sari, 1998; Panaitescu and Meszaros, 1998; Granot et al., 1999), which smooths the spectral and temporal breaks (Granot and Sari, 2002). The sharp transition in the blastwave dynamics adopted in analytical models is also an approximation. As a result, the sharp breaks predicted in the analytical models usually do not exist.

• Since the strength of the shock is continuously decreasing as the blastwave decelerates, the magnetic field strengths continuously decay in the shocked region. Electrons therefore cool in a varying magnetic field, which leads to a very smooth or non-existence of $\nu_c$ (Uhm and Zhang, 2013b), see also van Eerten and Wijers (2009). In the fast cooling regime, exactly the same effect makes the fast cooling spectrum harder (Uhm and Zhang, 2013a) than $F_\nu \propto \nu^{-1/2}$ proposed by Sari et al. (1998). In view of this, a sharp temporal or spectral break observed in GRB afterglow lightcurve or spectrum must not be associated with electron cooling (Uhm and Zhang, 2013b).

• All the analytical models reviewed in this article consider synchrotron radiation only. Synchrotron self-Compton (SSC) effect may be important in the afterglow phase (Wei and Lu, 1998; Dermer et al., 2000; Zhang and Mészáros, 2001b). Invoking synchrotron self-Compton (SSC) would complicate the matter. In particular, it would enhance cooling by a factor of $(1+Y)$, where $Y = L_{IC}/L_{\text{syn}} = U_{ph}/U_B$, $L_{IC}$ and $L_{\text{syn}}$ are the luminosities of the SSC and synchrotron components, respectively, and $U_{ph}$ and $U_B$ are the energy densities of the synchrotron photons and magnetic fields, respectively. The detailed treatments of the SSC effect
can be found in Sari and Esin (2001) and Gao et al. (2013). During
the reverse shock crossing phase, besides SSC in the reverse shock and
forward shock regions, scattering of photons from the other shock by
electrons from both shocked regions can be also important, which make
more complicated spectra and lightcurves (Wang et al., 2001a,b).

• Only adiabatic models are reviewed in the paper. In the literature, ra-
diative models have been also discussed (e.g. Sari, 1997; Böttcher and Dermer,
2000). However, since $\epsilon_e$ is usually small, a GRB blastwave cannot
be fully radiative even if electrons are in the fast cooling regime. A
partially radiative fireball and its dynamical evolution have been dis-
cussed by various authors (e.g. Huang et al., 1999, 2000; Pe’er, 2012;
Nava et al., 2012) and the detailed lightcurves of these cases have been
calculated by Wu et al. (2005).

• Numerical simulations are needed to well describe the transitions among
various phases. For example, the analytical models in Phase 1 (reverse
shock crossing phase) and Phase 2 (self-similar phase) do not match
exactly. After reverse shock crossing, how the blastwave self-adjusts
itself to the Blandford-McKee profile can be only addressed by numeri-
cal simulations (e.g. Kobayashi and Sari, 2000). Sideway expansion
after the “jet break” phase and the transition from the ultra-relativistic
phase to deep Newtonian phase all need numerical simulations to re-
solve the details (Cannizzo et al., 2004; Zhang and MacFadyen, 2009;
van Eerten and MacFadyen, 2012).

• The lightcurves involving collimated jets are complicated and usually
require numerical treatments. Even for a uniform jet, the shape of
the jet break may depend on the viewing angle from the jet axis
(Granot et al., 2002; van Eerten and MacFadyen, 2012). If the viewing
angle is outside the jet cone, one expects a variety of lightcurves for
the so-called “orphan afterglows”, which cannot be properly addressed
analytically. More complicated jets invoke angular structure with de-
creasing luminosity and Lorentz factor with respect to the jet axis
(Mészáros et al., 1998). The commonly discussed the jet structures in-
clude power law (Mészáros et al., 1998), Gaussian (Zhang et al., 2004),
and two-component conical jets (Berger et al., 2003; Racusin et al.,
2008). An on-axis observer would see a steeper lightcurve than the
isotropic case (Mészáros et al., 1998; Dai and Gou, 2001; Panaitescu,
For an off-axis observer (Rossi et al., 2002; Zhang and Mészáros, 2002a), the lightcurve may show a jet-break-like feature as the jet axis enters the field of view, but the exact shape of the break depends on the angular structure of the jet and the viewing angle (Kumar and Granot, 2003; Granot and Kumar, 2003). The two-component jets can show more complicated lightcurve behaviors (Huang et al., 2004; Peng et al., 2005).

It is possible that due to continuous energy injection or ejecta Lorentz factor stratification, a long-lived reverse shock may continue to exist, and the blastwave never enters the Blandford-McKee phase. The long-lasting reverse shock can show rich afterglow lightcurve features (Uhm et al., 2012), which may show up above the forward shock contribution if the reverse shock emission is enhanced. A more extreme view is that the entire observed afterglow is of a reverse shock origin (Uhm and Beloborodov, 2007; Genet et al., 2007).

Analyses of early afterglow data (Fan et al., 2002; Zhang et al., 2003; Kumar and Panaitescu, 2003) and theoretical considerations (Usov, 1992; Mészáros and Rees, 1997b; Metzger et al., 2011; Lei et al., 2013) suggest that the GRB central engine is likely magnetized. The GRB ejecta therefore likely carries a certain degree of magnetization. The reverse shock models presented here apply to low-magnetization cases. For moderate to high magnetization, the shock jump conditions and the strength of reverse shock are modified (Zhang and Kobayashi, 2005; Fan et al., 2004), and numerical simulations are needed to achieve precise results (Mimica et al., 2009). Also numerical simulations (Sironi and Spitkovsky, 2009) suggest that electron acceleration becomes suppressed in a magnetized shock, which would also affect the predicted synchrotron radiation flux.

All the models invoke constant microphysics parameters $\epsilon_e$ and $\epsilon_B$. In principle, these parameters may evolve with time also, and some authors have considered such more complicated models (e.g. Ioka et al., 2006; Fan and Piran, 2006).

More complicated afterglow models invoke density bumps (Dai and Lu, 2002; Dai and Wu, 2003; Nakar and Granot, 2007), violent energy injection into the blastwave via collision from a fast shell ejected at late
times (Zhang and Mészáros, 2002b; Geng et al., 2013), and patchy jets (Kumar and Piran, 2000; Ioka et al., 2005).

• Finally, in the early afterglow phase, additional physical processes may modify the blastwave dynamics. These include pair loading effect caused by interaction between radiation front and ambient medium (Madau and Thompson, 2000; Thompson and Madau, 2000; Mészáros et al., 2001; Beloborodov, 2002) and neutron decay effect from a neutron-rich ejecta (Derishev et al., 2001; Beloborodov, 2003; Fan et al., 2005).

Table 22: Collection of figure numbers corresponding to different dynamical models and initial spectra regimes.
Figure 1: All possible forward shock lightcurves during Phase 1 (reverse shock crossing phase), for thin shell ISM model and the initial characteristic frequency order $v_a < v_m < v_c$. The notations $t_{i+}, i = a, m, c$ denote frequency regime change from $v_i > v$ to $v_i < v$; $t_{i-}, i = a, m, c$ denote frequency regime change from $v_i < v$ to $v_i > v$; $t_{ij}, \{i, j\} = a, m, c$ denote frequency regime change from $v_i > v_j$ to $v_i < v_j$. The title for each sub-figure is the initial spectral regime of the observed frequency $v$.

Figure 44: Same as Fig. 43 but with the initial characteristic frequency order $\nu_m < \nu_a < \nu_c$. 
Figure 45: Example light curves in the radio, optical and X-ray bands for a set of typical parameter values (see text). The left and right panels are for the ISM and wind medium, respectively. In each panel, from top to bottom are the lightcurves in the radio, optical and X-ray band, respectively. Notations are the same with other Figures. The parameters $T_{\text{cut}}$, $T_{\text{j}}$ and $T_{\text{N}}$ denote $\nu_{\text{cut}}$ crossing time, the shock crossing time, jet break time, and the transition time to the Newtonian phase, respectively. The solid and dashed lightcurves denote contributions from the forward and reverse shock, respectively. The 4 different phases of forward shock emission are marked with 4 different colors. Notice that the reverse shock light curves have a sharp ending, which corresponds to time beyond which no on-axis electron radiation contributes to the band (i.e. after shock crossing and $\nu > \nu_{\text{cut}}$). In reality, there should be emission from high latitudes during these phases, so in these regimes there should be a steeply-decaying lightcurve with slope $-(2 + \beta)$, where $\beta$ is the flux density spectra index in the band [Kumar and Panaitescu, 2000].
