(September 13, 2018)

We solve the coupled gap equations for the $\sigma$- and $\pi$-bands of MgB$_2$ in the vortex state and calculate the resulting field dependencies of the specific heat coefficient $\gamma$ and the thermal conductivity $\kappa$. The crucial parameters of the theory are the interband pairing interaction $\lambda_{\sigma\pi}$ and the ratio $s = \xi_\sigma/\xi_\pi$ of the coherence lengths. For reasonably small $\lambda_{\sigma\pi}$ and $s$, the small gap $\Delta_\pi$ decreases with increasing magnetic field $H$ much faster than the large gap $\Delta_\sigma$. This gives rise to the observed rapid increase of $\gamma_\sigma$ and $\kappa_\sigma$ for small fields while $\gamma_\pi$ and $\kappa_\pi$ exhibit conventional field dependencies. Inclusion of intraband impurity scattering yields fairly good agreement with experiments for applied fields along the $c$ axis.

Evidence for the for the existence of two superconducting gaps in MgB$_2$ is provided by the rapid rise of the specific heat coefficient $\gamma_\sigma(H)^2$ and the thermal conductivity $\kappa_\sigma(H)^3$ at very low fields. These measured field dependencies can be explained qualitatively by assuming two independent bands where the large s-wave pairing gap $\Delta_\sigma \equiv \Delta_1$ is associated with the two-dimensional $\sigma$-band and the small s-wave gap $\Delta_\pi \equiv \Delta_2$ is associated with the three-dimensional $\pi$-band. The steep rise of $\gamma_\sigma(H)^2$ and $\kappa_\sigma(H)^3$ can be explained qualitatively by assuming that the "virtual" upper critical field for $\Delta_\pi$ is much smaller than that of $\Delta_\sigma$. In the present paper we improve the theory of Ref. 4 by taking into account the interband pairing interaction while neglecting the interband impurity scattering which has been shown to be small. We first have to solve the two-band gap equations in the presence of the vortex lattices produced by a magnetic field. Generalization of the linearized gap equations near the upper critical field $H_{c2}$ to all averaged fields $H$ between $H_{c1}$ and $0$ yields, instead of the single gap equation of Ref. 4, the following coupled gap equations for the gaps $\Delta_i$ at $T = 0$:

$$\Delta_i = \sum_{j=1}^{2} \lambda_{ij} \int_{0}^{\omega_c} d\omega B_j(\omega, \Delta_j, \Lambda/v_j) \quad (i = 1, 2)$$

(1)

Here, the $\lambda_{ij}$ are the intra- and interband pairing interactions multiplied by the densities of states $N_i(0)$, and the $B_j$ are the spectral functions of the anomalous propagators for the Abrikosov vortex lattice:

$$B_i = \text{Re} \left[ \frac{-i \sqrt{\pi} 2 \Delta_\sigma (\Lambda/v_i) w(z_i)}{\{1 + 8 \Delta_\pi^2 (\Lambda/v_i)^2 [1 + i \sqrt{\pi} z_i w(z_i)]\}^{1/2}} \right],$$

(2)

$$z_i = 2(\omega + i \gamma_i) \Lambda/v_i; \quad \Lambda = (2 e H)^{-1/2}; \quad \gamma_i = \Gamma_i \Lambda;$$

(3)

$$\Delta_\pi = \Delta_i/D_i; \quad D_i = 1 - 2 (\gamma_i \Lambda/v_i) w(z_i).$$

(4)

The $\Gamma_i$ are the normal state impurity scattering rates, the $A_i$ are the field-dependent densities of states, the $v_i$ are the Fermi velocities perpendicular to the field, and the function $w(z)$ is defined in Ref. 4. For band 2 (the $\pi$-band) we assume a spherical Fermi surface. Then $v_2$ is replaced by $v_2 \sin \theta$ and $B_2$ and $D_2$ are averaged over the polar angle $\theta$ with respect to the direction of $H$. For brevity we omit here, and in the following, the terms containing $\sin \theta$ and the integrations over $d\theta \sin \theta$ from 0 to $\pi/2$. For band 1 (the $\sigma$-band) and the field along the $c$ axis, $\theta = \pi/2$ and thus $\sin \theta = 1$.

In the limit $H \to 0$ the vortex lattice constant $a = (2/\pi)^{1/2} \Lambda$ tends to infinity. Making use of the asymptotic expansion $w(z) \sim i/\sqrt{\pi} z$, the gap equations, Eq.(1), become

$$\Delta_{i0} = \sum_{j} \lambda_{ij} \int_{0}^{\omega_c} d\omega \text{Re} \left[ \frac{\Delta_{j0}}{(\omega^2 - \Delta_{j0}^2)^{1/2}} \right],$$

(5)

where the $\Delta_{i0}$ are the gap values at $T = 0$ in zero field. Here we have made use of the relation

$$(\omega + i \gamma_{i0})/\Delta_{i0}^\alpha = (\omega + i \gamma_{i0}) D_{i0}/\Delta_{i0} = \omega/\Delta_{i0}$$

(6)
which can be derived with the help of the expression for $D_i$ in Eq.(4). However, this relation only holds in the absence of interband impurity scattering.\textsuperscript{5}

With the help of the Abrikosov parameters, denoted by $\beta_i$, we now express $\Lambda/v_i$ in terms of the reduced field $h = H/H_{c2}$ and the zero-field gap $\Delta_0$:\textsuperscript{4}

$$
\Lambda/v_1 = (6\beta_1 h \Delta_{10}^2)^{-1/2}; \quad \Lambda/v_2 = s(6\beta_2 h \Delta_{20}^2)^{-1/2}; \quad s = (v_1/v_2)(\Delta_{20}/\Delta_{10}) = \xi_{10}/\xi_{20}.
$$

(7)

Employing these relations we can express the gaps $\Delta_i$ and the scattering rates $\Gamma_i$ in Eq.(2) by their ratios with respect to the $\Delta_0$, and we can convert the integrations over $\omega$ in Eq.(1) to integrations over the new variables $\Omega = \omega/\Delta_0$.

We then divide Eq.(1) by $\Delta_i$ and Eq.(5) by $\Delta_0$ and subtract the latter from the former. In this way we obtain two coupled equations for the two unknown functions $x_1(h)$ and $x_2(h)$ for given values of the parameters $\lambda_{ij}$, $\delta_i$, $\beta_i$, $r$, and $s$. The quantities $x_i$, $\delta_i$, and $r$ are defined by

$$
x_i = \Delta_i/\Delta_0; \quad \delta_i = \Gamma_i/\Delta_0; \quad r = \Delta_{20}/\Delta_{10}.
$$

(8)

In Fig. (1) we show the reduced gap functions $x_1(h)$ and $x_2(h)$ for 3 sets of parameter values: I) $\lambda_{11} = 1$, $\lambda_{22} = 0.28$, $\lambda_{21} = 0.17$, $\lambda_{12} = 0.23$, $\beta_1 = 1.15$, $\beta_2 = 1.58$, $s = 1/6$; II) $\lambda_{11} = 1$, $\lambda_{22} = 0.65$, $\lambda_{21} = 0.16$, $\lambda_{12} = 0.21$, $\beta_1 = 1.16$, $\beta_2 = 1.58$, $s = 1/6$. The gap ratio has been taken to be $r = 1/3$ and the reduced impurity scattering rates $\delta_i = \Gamma_i/\Delta_0$ are $\delta_1 = 0.5$ and $\delta_2 = 0.8$. The $\lambda$-matrix elements in I) and II) have been obtained from band structure calculations (Refs. 8 and 9, see the review, Ref. 10). The ratio of Fermi velocities is about $v_1/v_2 = 0.54$\textsuperscript{11} and the gap ratio $r$ ranges between about 1/3 and 0.44\textsuperscript{12,13} which yields a range of the ratio $s$ of coherence lengths (see Eq.(7)) between 0.18 and 0.24. While the function $x_1(h) \simeq (1-h)^{1/2}$ is rather independent of the choice of parameters, the function $x_2(h)$ depends sensitively on the values of $\lambda_{ij}$ and $s$. For vanishing interband coupling $\lambda_{21}$ we obtain approximately $x_2(h) \simeq (1-h/s^2)^{1/2}$ which goes to zero at a smaller effective upper critical field $H_{c2}^s = s^2H_{c2}$ where $s \simeq \xi_{10}/\xi_{20}$ (see Eq.(7)). Thus we see that $H_{c2}^s$ corresponds to the "virtual" upper critical field for the $\pi$-band which was introduced in Ref. 2 as the field above which the overlap of the vortex cores with large radius $\xi_{20}$ (see the STS measurements of Ref. 12) drives the majority of the $\pi$-band electrons normal.

In Fig.(2) we have plotted our results for the zero energy density of states $A_i(\omega = 0)$ obtained from the expression for $A_i$ (given by Eq.(2) with the numerator set equal to 1) by inserting the previously calculated gap ratios $x_i(h)$ together with Eqs.(7) for the functions $\Lambda(h)/v_i$. $A_2$ is obtained by averaging $A_2(\theta)$ over the polar angle $\theta$. We note that it is important to calculate the impurity scattering rates $\gamma_i = \Gamma_i A_i(h)$ self-consistently. One sees from Fig. (2) that $A_2(h)$ rises steeply for small fields $h$ and then becomes almost constant above $h \sim 0.2$. The slope at $h = 0$ and the downward curvature for low fields increase as $s$ is decreased from 1/4 to 1/6. The function $A_1(h)$ is very similar to the function obtained previously for a single band.\textsuperscript{4} The initial steep rise of $A_2(h)$ for $s = 1/6$ qualitatively fits the data points for the contribution of the $\pi$-band to the specific heat coefficient $\gamma(H)$\textsuperscript{2}. The function $A_1(h)$ corresponds to the straight line assumed in Ref. 2 for the $\sigma$-band contribution to $\gamma(H)$ for fields applied along the $c$ axis.

We turn now to the calculation of the in-plane electronic thermal conductivity $\kappa_{\pi}(h)$ which is given at $T = 0$ by the expression in Ref. 14. Again it is important to take into account the renormalization of the gap by the function $D_i$ in the presence of impurity scattering (see Eq.(13) of Ref. 4). By inserting the functions $x_i(h)$ obtained from the gap equations, Eq.(1), and the functions $\Lambda(h)/v_i$ from Eq.(7) into the expressions for the ratios $\kappa_{\pi}/\kappa_n$ we obtain, for applied fields $H$ along the $c$ axis, the thermal conductivity ratios $\kappa_{\pi}(h)/\kappa_n$ shown in Fig.3. It should be noted that the $\pi$-band contribution $\kappa_{\pi}(h)/\kappa_n$ has been obtained as an average over the polar angle $\theta$ by including the factor $(3/2)\sin^2 \theta$ which arises from the square of the group velocity in the $ab$ plane. The curve for the $\sigma$-band conductivity $\kappa_{\sigma}(h)/\kappa_n$ turns out to be very similar to the curve obtained in Ref. 4 for a single band with the same impurity scattering rate $\delta_i = 0.5$. The curve $\kappa_{\pi}(h)/\kappa_n$ for the $\pi$-band contribution with $\delta_2 = 0.8$ rises almost linearly with $h$ where the slope near $h = 0$ and the downward curvature for low fields increase as $s$ is decreased from 1/4 to 1/6. For applied fields perpendicular to the $c$ axis, the measured thermal conductivity $\kappa_{\pi}$ first rises steeply for small fields and then saturates while, for fields along the $c$ axis, it exhibits an upward curvature towards $H_{c2}^s$.\textsuperscript{3} These different behaviors have been explained by separating the individual contributions of the $\pi$- and $\sigma$-bands. Then $\kappa_{\pi}$ rises steeply with $H$ and approximately attains its normal-state value at a small field and $\kappa_n$ first rises very slowly and then curves upward towards $H_{c2}^s$.\textsuperscript{3} These experimental curves are similar to our results for $s = 1/6$ shown in Fig. (3).

We now briefly discuss the parameter values and approximations that have been used to derive our results. We have seen that the rapid increase of the specific heat coefficient $\gamma_{\pi}(h)/\gamma_n$ and the thermal conductivity ratio $\kappa_{\pi}(h)/\kappa_n$ with increasing field $h = H/H_{c2}$ is due mainly to the $\pi$-band contribution. The reason is that the gap $\Delta_2(h)$ associated with the $\pi$-band almost closes at the so-called "virtual" upper critical field\textsuperscript{2} $H_{c2}^s \sim s^2H_{c2}$ because the ratio $s = \xi_{10}/\xi_{20}$ of the coherence lengths of the $\sigma$- and the $\pi$-bands is much smaller than 1. For the most important parameters entering our gap equations, $s$ and $r = \Delta_{20}/\Delta_{10}$, we have used the values $r = 1/3$ and $s = 1/4$, and 1/6 which are
based on various experiments on MgB$_2$. The field dependence of the gap ratio $x_1(h) = \Delta_1/\Delta_{10}$, and thus of the contributions to $\gamma_1$ and $\kappa_1$, arising from the $\sigma$-band, are nearly the same as those obtained for an independent single $\sigma$-band, indicating that the effect of the interband coupling $\lambda_{12}$ is rather small. However, the field dependence of $x_2(h) = \Delta_2/\Delta_{20}$ differs substantially from that for the independent single $\pi$-band with an effective upper critical field $h^*_{c2} = s^2$ as can be seen from Fig. (1). This is because $x_2(h)$ is non-zero between $h^*_{c2}$ and $h = 1$ due to the effect of the interband coupling $\lambda_{21}$. This shows that superconductivity survives even though the vortex cores for the $\pi$-band with giant radius $\xi_{20}$ start to overlap for $h > h^*_{c2}$. As can be seen in Fig. (1), the curve for $x_2(h)$ is very sensitive to the values of $\lambda_{ij}$ and $s$. We find that the experimental contributions to $\gamma$ and $\kappa$ arising from the $\pi$-band can be fitted by taking the $\lambda_{ij}$ given by band structure calculations. The other crucial parameter values needed to obtain good fits of the data are $r = 1/3$ and $s = 1/6$ which lie in the ranges obtained from experiment. The other parameter values used in our numerical calculations are the reduced impurity scattering rates $\delta_1 = 0.5$ and $\delta_2 = 0.8$ which have been estimated from the relevant experiments. It turns out that even for these moderately large impurity scattering rates it is very important to take into account the renormalization of the gap (see Eq. (4)) which leads to a large reduction of the effect of impurity scattering in comparison to that calculated without the function $D$. It is also important that the calculation of the scattering rate $\gamma_i = \Gamma_i A_i(h)$ in the Born limit be carried out self-consistently together with the calculation of the zero-energy density of states $A_i(h)$. This yields $A_i(0) = 0$, as it should. The shape of the Fermi surface (FS) and the direction of the applied field play an important role because the spectral functions $B_i$ in Eq. (2) have to be averaged over the corresponding FS where the velocity $v_i$ denotes the component $v_{i\perp}(p)$ perpendicular to $H$. For the spherical FS we have assumed for the $\pi$-band, $v_{i\perp}(p) = v \sin \theta$, where $\theta = \angle(p, H)$. In the limit $\theta \to 0$ the function $B$ approaches the BCS spectral function of the anomalous propagator. We find that the results for the averages over the polar angle $\theta$ do not differ significantly from the results obtained by setting $\theta = \pi/2$. This means that the quasiparticles moving perpendicular to the vortex axes yield the dominant contributions to $\gamma$ and $\kappa$. We have approximated the $\pi$-band FS by a sphere whereas the $\lambda_{ij}$ have been calculated for the actual FS. This actual FS can be modeled by a half-torus which yields, with the $\lambda$-matrix of Ref. 8 and small $s$, results which agree qualitatively with ours shown in Figs. 1 and 2 for $s = 1/6$. Finally it should be pointed out that we have employed the Abrikosov ground state of the vortex lattice although, in particular at lower fields, a Landau-level expansion or a variational expression is needed to describe the distorted vortex lattice. The results for $\gamma_i(h)/\gamma_n$ and $\kappa_i(h)/\kappa_n$ shown in Figs. (2) and (3) for the $\sigma$- and $\pi$-bands should still be added by weighting them with the corresponding density of states.

In conclusion we can say that our two-band theory for the vortex state in MgB$_2$ can satisfactorily account for the observed field dependence of the specific heat coefficient $\gamma$ and the thermal conductivity $\kappa$. The small gap $\Delta_2$ associated with the $\pi$-band decreases with increasing field $H$ much faster than the large $\sigma$-band gap $\Delta_1$ which shows conventional field dependence. This gives rise to the rapid increase of $\gamma$ and $\kappa$ at small fields. Due to a small interband pairing interaction $\lambda_{21}$, the gap $\Delta_2$ remains finite even in the field region where the large $\pi$-band vortex cores of radius $\xi_{20}$ overlap. This leads to smooth evolution of the $\pi$-band contributions to $\gamma$ and $\kappa$ to their normal state values near a "virtual" upper critical field $H^*_{c2} \approx s^2 H_{c2}$ which is much smaller than $H_{c2}$ because the ratio $s = \xi_{10}/\xi_{20}$ is much smaller than 1. The Fermi surface topology and the impurity scattering have relatively small influence on the field dependence of $\gamma$ and $\kappa$ for fields applied along the $c$ axis.

We thank T. Dahm for valuable discussions.

FIG. 1. Reduced gaps $x_i(h) = \Delta_i/\Delta_{i0}$ for the $\sigma$-band and $x_2(h) = \Delta_2/\Delta_{20}$ for the $\pi$-band vs reduced magnetic field $h = H/H_{c2}$ for applied fields along the c axis. The upper curves are for $x_1$ and the lower curves for $x_2$. The pairing interaction matrices $\lambda_{ij}$ have the values given in Ref. 8 (our parameter sets I, $s = 1/6$, and IA, $s = 1/4$) and in Ref. 9 (set II, $s = 1/6$) where $s$ is the ratio of coherence lengths $s = \xi_{10}/\xi_{20}$. The curves correspond to the parameter sets IA, I, and II, from top to bottom. The reduced impurity scattering rates $\delta_i$ are $\delta_1 = 0.5$ for the $\sigma$-band and $\delta_2 = 0.8$ for the $\pi$-band.
Fig. 2

FIG. 2. Specific heat coefficients, or zero-energy densities of states, $\gamma_{si}/\gamma_{ni} = A_i$, $(i = 1, 2)$ vs $h$ for the parameter values of Fig.(1). The lower curves are for the $\sigma$-band, $i = 1$, and the upper curves are for the $\pi$-band, $i = 2$, for parameter sets Ia, I, and II, from bottom to top.
FIG. 3. Reduced electronic thermal conductivities, $\kappa_{si}/\kappa_{ni}$, ($i = 1, 2$) vs $h$ for the parameter values of Fig.(1). The lower curves are for the $\sigma$-band, $i = 1$, and the upper curves are for the $\pi$-band, $i = 2$, for parameter sets Ia, I, and II, from bottom to top.
