(Dated: January 12, 2013)

We study the spin dynamics in a high-mobility two dimensional electron gas (2DEG) with generic spin-orbit interactions (SOIs). We derive a set of spin dynamic equations which capture the purely exponential to the damped oscillatory spin evolution modes observed in different regimes of SOI strength. Hence we provide a full treatment of the D’yakonov-Perel’s mechanism by using the microscopic linear response theory from the weak to the strong SOI limit. We show that the damped oscillatory modes appear when the electron scattering time is larger than half of the spin precession time due to the SOI, in agreement with recent observations. We propose a new way to measure the scattering time and the relative strength of Rashba and linear Dresselhaus SOIs based on these modes and optical grating experiments. We discuss the physical interpretation of each of these modes in the context of Rabi oscillation.

I. INTRODUCTION

In recent years research in semiconductor based devices has incorporated the spin degree of freedom as a new state variable in novel electronic devices with potential for future applications. The SOI is a key tool to electrically manipulate the spin and realize such devices. However, the SOI is a double-edged sword because it will also induce random spin precession through an angle $\Omega_{so}\tau$ between collisions with impurities, where $\tau$ is the electron life time. This is known as the D’yakonov-Perel’s(DP) mechanism and dominates the spin relaxation in the technologically important III-V semiconductors. Therefore it is very important to understand fully the DP mechanism for the possible application and further development of spintronics devices. Although the study of DP mechanism in semiconductors in the presence of SOI was initiated long ago, most of the theoretical research focuses on the weak spin-orbit coupling (SOC) regime where $\Omega_{so}\tau \ll 1$. However, as high-mobility 2DEG systems are created, it is now not difficult to reach the strong SOI regime experimentally where $\Omega_{so}\tau > 1$ at low temperatures as long as the mobility is approximately larger than $1.2 \times 10^5$ cm$^2$/Vs. The spin evolution in this regime is observed to be damped oscillations in the uniform and nonuniform spin polarized system, which can not be described by spin-charge drift-diffusion equations derived for the weak SOC regime and lacks a clear theoretical explanation.

Here, we study the spin dynamics theoretically from the weak to strong SOC regime. The method we use is linear response theory. We derive a set of spin dynamical equations in the uniform spin polarized 2DEG with different SOIs. We show analytically that for $\Omega_{so}\tau > \frac{1}{2}$ the damped oscillations appear. The decay rate in this case is proportional to $\frac{1}{\tau}$ instead of $\tau$ as in the weak SOC regime. The cubic Dresselhaus term is shown to reduce the oscillatory frequency and increase the decay rate in the strong SOC regime. The spin dynamics for non-uniform spin polarization with spatial frequency $q$ in the strong SOC regime is obtained by solving the equations numerically. We discuss these dynamics by using the analogy with Rabi oscillations between two momentum states which are gaped by the SOI. Our results match the experimental observation quantitatively. We also show how to exploit our analysis to create an accurate measurement of the strength of Rashba and linear Dresselhaus SOIs in a 2DEG, hence allowing a full characterization of different device samples which will lead to a more accurate modeling and predictability of the optimal operating physical regimes.

II. MODEL HAMILTONIAN AND DENSITY MATRIX RESPONSE FUNCTION

Normally in the 2-D semiconductor heterostructures, we have three kinds of SOIs, namely the linear Rashba term and the linear and cubic Dresselhaus terms. The Hamiltonian takes the form

$$H = \frac{k^2}{2m} + h(k) \cdot \hat{\sigma},$$

where $h(k)$ is the effective magnetic and contains Rashba, linear and cubic Dresselhaus terms which are

$$h_R(k) = \alpha(-k_y, k_x),$$
$$h^{D1}(k) = \beta_1(k_y, k_x),$$
$$h^{D3}(k) = -2\beta_3 \cos 2\theta(-k_y, k_x),$$

where $k_f$ is the Fermi wave vector. Here we take $\theta$ as the angle between the wave vector $k$ and the [110] direction which is the $x$ axis in our coordinates. The above SOIs split the spin-degenerate bands and dominate the spin dynamics in the 2DEG. The corresponding SOC Hamiltonian and the spin precession frequency $\Omega_{so}$ takes the form:

$$H^{so} = (\lambda_1 - 2\beta_3 \cos 2\theta)k_x\sigma_y + (\lambda_2 + 2\beta_3 \cos 2\theta)k_y\sigma_x,$$

where $\lambda_1 = \alpha + \beta_1$, $\lambda_2 = \beta_1 - \alpha$. 

arXiv:1102.3170v1 [cond-mat.mtrl-sci] 15 Feb 2011
We derive the spin dynamic equations from the density matrix response function [3] used previously in Refs. 3 and 4 in the weak spin-orbit coupling regime $\Omega_{so}\tau \ll 1$. The spin diffusion is dominated by the pole of the spin-charge diffusion propagator or "diffuson":

$$ D = [1 - \hat{I}]^{-1} \quad (6) $$

and

$$ \hat{I}_{\sigma_1,\sigma_2,\sigma_3,\sigma_4} = \frac{1}{2m\tau} \int \frac{d^2k}{(2\pi)^2} G^A_{\sigma_1\sigma_1}(k,0)G^R_{\sigma_2\sigma_4}(k + q,\Omega), \quad (7) $$

where $\sigma_i$ is just a number which can be 1 or 2. Here, we will calculate the diffusion matrix exactly and make it valid in any SOC regime. It is more convenient to write the Eq. 7 in a classical charge-spin space

$$ I^{\alpha\beta} = \text{Tr}(\sigma_\alpha \hat{I} \sigma_\beta), \quad (8) $$

where $\alpha,\beta = c, x, y, z$. We have:

$$ i\Omega\tau = \frac{1}{2} \left( 2 - \sqrt{2} \sqrt{1 - 2(\Omega_{so}\tau)^2} + \sqrt{1 - 4(\Omega_{so}\tau)^2 + 4(\Omega_{so}\tau)^4 \gamma^2} \right). \quad (10) $$

Note that $\gamma \leq 1$ and

$$ (1 - 4(\Omega_{so}\tau)^2 + 4(\Omega_{so}\tau)^4 \gamma^2) \leq (1 - 2\Omega_{so}^2 \tau^2). $$

Therefore, as long as $1 - 4(\Omega_{so}\tau)^2 + 4(\Omega_{so}\tau)^4 \gamma^2 < 0$, a non-equilibrium spin polarization will exhibit damped oscillation with respect to time.

In the case of $\alpha = 0$ or $\beta = 0$, the eigenmode takes the form

$$ i\Omega\tau = \frac{1}{2} - \frac{1}{2} \sqrt{1 - 4\Omega_{so}^2 \tau^2}. \quad (11) $$

When $\Omega_{so}\tau > 1/2$, the decay rate changes from the exponential decay mode to the damped oscillation mode. The oscillatory frequency in the clean limit, $\tau \to \infty$, is $\Omega_{so}$. Several experiments [1, 2, 4] observe the damped oscillation mode of spin evolution at low temperature. However, their analysis did not explain qualitatively when this kind of mode appears but just qualitatively argue that it appears in the regime where $\Omega_{so}\tau > 1$. Our theory agrees with the recent experiments [1, 2] in which the authors observe that when the temperature is above 5 K, the oscillation will disappear. In their system, this corresponds to $\Omega_{so}\tau_p^* \approx 0.48$, which is close to our result $1/2$. Here $\tau_p^*$ is different to the transport scattering time $\tau_p$ obtained from the mobility; this difference is due to the Coulomb interaction effect on spin-currents and spin dephasing [4].

### III. UNIFORM SPIN POLARIZATION

In the case of a uniform spin polarized 2DEG system, i.e. $q = 0$, because the effective magnetic field due to the SOI has inversion symmetry in momentum space, only the diagonal elements of the diffusion matrix are nonzero, which means the spin $x$, $y$, and charge are not coupled to each other. Therefore, when considering the uniform spin polarization along the $z$ direction, only $I^{zz}$ needs to be calculated. First, we neglect the cubic Dresselhaus term which is normally much smaller than the linear Dresselhaus term. We find the pole of diffusion matrix by solving the equation

$$ 1 - I^{zz} = 1 - \frac{1 - i\Omega\tau}{\sqrt{(1 - i\Omega\tau)^2 + (\Omega_{so}\tau)^2} - 2(\Omega_{so}\tau)^2} = 0, \quad (9) $$

where $\Omega$ is the frequency of the spin evolution, $\Omega_{so} = 2\sqrt{\alpha^2 + \beta^2} k_f$, $\gamma = \frac{2\alpha\beta}{\alpha^2 + \beta^2} = \frac{\lambda^2 - \lambda_5^2}{\lambda_1 + \lambda_5^2}$, $k_f$ is the Fermi wave vector and $I^{zz}$ is obtained from the exact angular integration of Eq. (7). The details of calculating $I^{zz}$ are shown in the appendix. The eigenmode of the spin dynamical evolution takes the form

$$ I^{zz} = \frac{1 - i\Omega\tau}{\sqrt{(1 - i\Omega\tau)^2 + \Omega_{so}^2 \tau^2(1 + 2(\frac{\Omega_{so}}{\Omega})^2 - 2\frac{\Omega_{so}}{\Omega} \tau^2)} \times \frac{1}{\sqrt{(1 - i\Omega\tau)^2 + \Omega_{so}^2 \tau^2}}} \quad (12) $$

As the linear and cubic Dresselhaus terms always coexist, we have to consider the effect of cubic Dresselhaus term on Eq (11). We do this in the simplest case, when Rashba coefficient is zero. In this case, the diffusion matrix element $I^{zz}$ takes the form...
This ratio is plotted in Fig. 2 with respect to the frequency when the real (imagine) value of the damped oscillatory frequency. To show the effect of the cubic Dresselhaus term, the exponential decay rate and decrease the oscillatory frequency. Eq. (11, 13) show that the cubic term will increase the exponential decay rate and the oscillatory frequency \( \Omega \) approach \( \Omega_{so} \), when \( \Omega_{so} \tau > \frac{1}{2} \).

where \( \Omega_{so} = 2\beta_1 k_f \) and \( \delta = 2\frac{\beta_3}{\beta_1} (1 - \frac{\beta_3}{\beta_1}) \). The corresponding spin decay rate is

\[
\begin{align*}
\dot{\Omega} = 1 - & \\
\frac{1}{2} & \sqrt{(1 + \sqrt{1 - 4\Omega_{so}^2 \tau^2 + 2\Omega_{so}^2 \tau^2 \delta + \Omega_{so}^4 \tau^4 \delta^2) - \Omega_{so}^4 \tau^4 \delta^2}}.
\end{align*}
\]

(13)

Eq. (11, 13) show that the cubic term will increase the exponential decay rate and decrease the oscillatory frequency. To show the effect of the cubic Dresselhaus term, the real (imagine) value of the damped oscillatory frequency when \( \beta_3 \neq 0 \) is divided by the value when \( \beta_3 = 0 \). This ratio is plotted in Fig. 2 with respect to \( \beta_3/\beta_1 \) and \( 2\beta_1 \tau \). When \( \frac{\beta_3}{\beta_1} < 0.2 \), the effect of the cubic term is very small and can be neglected. In this case, the damped decay rate is always equal to \( \frac{\Omega_{so}^2}{\tau^2} \) as long as \( \Omega_{so} \tau > \frac{1}{2} \) and the oscillatory frequency \( \Omega \) approach \( \Omega_{so} \) when \( \Omega_{so} \tau \gg 1 \).

This provides a reliable way to measure the momentum scattering time \( \tau \). Further, the strength of the linear Dresselhaus SOI can be obtained from Eq. (11) once we know \( \tau \) and the oscillatory frequency from the measurements. These will be discussed in a later section.

Now, let us choose \( \alpha = \beta_1 \) which is a more unique case and gives us the persistent spin helix for special \( q \) values. \( 14, 15 \). For the uniform spin polarization, the decay rate of the spin satisfies

\[
\dot{\Omega} = 1 - \sqrt{1 - 2(\Omega_{so} \tau)^2},
\]

where \( \Omega_{so} = 2\sqrt{\alpha^2 + \beta_1^2} k_f \). The damped oscillation mode will happen when \( \Omega_{so} \tau = 2\sqrt{2}k_f \tau > \frac{\sqrt{2}}{2} \), say \( 2\alpha k_f \tau > 1/2 \) which is the same as the pure Rashba or Dresselhaus case. The oscillating frequency in the clean limit is \( \sqrt{2} \Omega_{so} = 4\alpha k_f \), which is the two fold of the frequency for the pure Rashba or Dresselhaus case. On the other hand, as the real part of \( \dot{\Omega} \tau \) is equal to \( 1 \) when damped oscillation mode appear, the damped decay rate is also the two fold of the case of the pure Rashba or Dresselhaus.

**IV. SPIN DYNAMICS AND RABI OSCILLATION**

Before we discuss the spin dynamics for the nonuniform spin polarization system, let us give a physical explanation of the result we have obtained. We can construct a simple physics picture to describe the spin polarized wave theoretically. Taking the Rashba SOI for example, we define the eigenstates \( |\phi_k^M \rangle \) to denote the majority band and the \( |\phi_k^S \rangle \) to denote the minority band. The spin of the eigenstate of the SOC 2DEG lies in the \( x-y \)
plane. The majority electron has opposite spin to the minority electron when they have the same wave vector \( k \). As a result, The spin polarization along the \( z \) direction

can be obtained by the superposition of the majority and minority bands as

\[
\Psi_{\uparrow q} = A\left[ \sum_k e^{(\epsilon_\uparrow - \epsilon_f) / 4\sigma^2} \frac{1}{\sqrt{2}} (|\phi_k^a\rangle + |\phi_{k+q}^b\rangle) \right] + A\left[ \sum_k e^{(\epsilon_\uparrow - \epsilon_f) / 4\sigma^2} \frac{1}{\sqrt{2}} (|\phi_k^b\rangle + |\phi_{k+q}^a\rangle) \right],
\]

where \( A \) is the normalization coefficient, \( \Psi_{\uparrow q} \) is the wave function of the system with positive spin polarization along \( z \) direction with wave vector \( q \) and the function \( e^{(\epsilon_\uparrow - \epsilon_f) / 4\sigma^2} \) restrict the spin polarization electrons only in the narrow range \( \frac{\epsilon_f}{\sigma} \ll \epsilon_f \) around the Fermi energy \( \epsilon_f \). The expectation value \( \langle \Psi_{\uparrow q}, \sigma_z \cos q' x | \Psi_{\uparrow q} \rangle \) is nonzero only when \( q' = q \) which confirms that \( \Psi_{\uparrow q} \) can describe the spin polarized wave. The energy difference of these two electrons in the first(second) term on the right hand side of Eq (15) is \( \Delta_1(2) \) as shown in Fig. 3. Therefore, \( \Psi \) can be treated as a collective two level system with two Rabi frequencies \( \Omega_{1(2)} = \frac{\Delta_1(2) \hbar}{4} \). For the uniform spin polarization means \( q = 0 \) and there is only one Rabi frequency \( \Omega_0 = \frac{\Delta_0}{4\hbar} \) Fig. 3. When the system is very clean, our results, Eq. (11,13), show that the spin evolution is damped oscillation and the oscillatory frequency is the Rabi frequency. It is a little surprising that when \( \alpha = \beta \), although the SOC gap \( \Delta_0 \) is not a constant, the oscillatory frequency is corresponding to the maximum splitting energy \( 4\epsilon_k f \) instead of the average splitting energy \( 2\sqrt{2\Delta_0 \epsilon_f} \). In the weak SOC regime, the disorder is so strong that the splitting energy due to the SOC is completely submerged in the broadening of the band \( \frac{\hbar}{Q} \). Therefore, the spin polarization just exponential decays. For the non-uniform spin polarization case, since there are two Rabi oscillation frequencies \( \Omega_1 \) and \( \Omega_2 \), we expect to have two damped oscillatory modes in the clean system corresponding to energy differences \( \Delta_1 \) and \( \Delta_2 \) respectively in Fig. 3.

V. NON-UNIFORM SPIN POLARIZATION

In the case of the non-uniform spin polarized 2DEG, the initial state is a spin wave with wave vector \( q \), the momentum \( k \) is coupled to \( k + q \) which makes the center of the Fermi sea be shifted to near \( q \). The average magnetic field is nonzero and the off diagonal elements of the diffusion matrix appear to couple the different spin component. When only considering the Rashba or linear Dresselhaus SOI, our numerical calculation does have two kinds of spin dynamical modes which are shown in Fig. 4.

![Figure 4](image-url)

FIG. 4. The fast oscillatory mode of the nonuniform spin dynamics in the strong SOC regime when the system only has bulk inversion asymmetry. (a) The normalized exponential decay rate, \( \Im(i\tau) \) increase with increasing \( q \) and approach to one at large \( q \). (b) The nonzero normalized oscillatory frequency, \( \Im(i\tau) \), increases linearly at large \( q \), the slope is close to \( \Omega_{\alpha\tau} \) and its value approaches \( \Omega_{\alpha}(1 + \frac{q}{Q}) \).

The damped oscillatory modes at large \( q \) can be approximately written as

\[
i\Omega = 1 - \sqrt{1 - (\Omega_{\alpha\tau})^2(1 + \frac{q}{Q})^2}
\]

where \( Q = 2m\lambda_1 \).

The two damped oscillatory mode and their oscillatory frequency satisfy our expectation based on the Rabi oscillation viewpoint. When \( q \) increases, the Rabi frequency of the faster mode always increases which makes the damped oscillatory mode appear even when \( \Omega_{\alpha\tau} < \frac{1}{2} \). This means we can expect to observe the oscillation for the nonzero spin polarization at higher temperature than for the uniform spin polarization. In Ref. [11] where
The spin dynamics in the strong SOC regime have several special characters which can be used in experimental measurements.

**Momentum scattering time τ_p**: In the spin dynamics, the Coulomb interaction plays an important role in determining the momentum scattering time τ_p\textsuperscript{22,23}. This is quite different to the charge transport case where electron-electron(e-e) interaction will not change the ensemble momentum scattering τ_p which determines the electron mobility. This difference is called spin Coulomb drag (SCD). In previous experimental work, SCD was observed through the spin diffusion coefficient D_s = 1/2τ_pΩ\textsuperscript{2} by fitting the spin decay rate in the weak SOC regime. Here, we provides a way to observe SCD in the strong SOC regime by directly measuring the momentum scattering time τ_p\textsuperscript{2}. Based on Eq\textsuperscript{11,13} when only Dresselhaus SOI is presented, the damped decay rate is always almost equal to 1/2 as long as Δ\textsubscript{D} < 0.2 which is easily realized in experiments\textsuperscript{12,15}.

**The strength of SOIs**: Here, we would like to emphasize that 2β\textsubscript{k}kfτ = 1/2 is a very important case and is corresponding to the transition point between pure exponential decay mode and damped oscillatory mode. The decay rate at this point is not only equal to 1/2τ_p, but also equal to 1/2τ_p when α = 0. This means that at this point we can obtain the strength of linear Dresselhaus SOI from the spin polarization decay rate. When 2β\textsubscript{k}kfτ = 1/2, we can increase the Rashba SOI by adding a gate voltage. As long as 0 < α < β\textsubscript{1}, according to Eq. 10, the spin evolution is still decay exponentially and the decay rate is (1 − Δ\textsubscript{D}^2)τ/τ_p where Ω\textsubscript{so} = 2√α^2 + β\textsubscript{2}^2k_f which gives us the strength of Rashba SOI.

**VII. CONCLUSION**

We have discussed the spin dynamics in the strong spin-orbit coupling regime. We describe quantitatively the special characters of the damped oscillatory mode in this regime. We also compare our result to the previous experimental data and find they match very well. Based on our theoretical results, a reliable way is proposed to measure the Rashba and Dresselhaus coefficients and electron momentum scattering time which is not corresponding to the mobility due to the Coulomb interaction. Furthermore, we find that the spin dynamics in the 2DEG can be treated as a collective two level system. This helps us semi-quantitatively understand the spin dynamics in the strong spin-orbit coupling regime. For the nonzero spin polarization case, we predict that there exist double damped oscillatory modes at large q and explain the persistent spin helix mode from the Rabi oscillation point of view.

port from DMR-0547875, NSF-MRSEC DMR-0820414, and SWAN-NRI. J. S. is a Cottrell Scholar of Research Corporation.

Appendix A: Spin dynamic matrix for the uniform spin polarization

In this section, we derive the spin evolution mode of the uniform spin polarization. According to Eq. (5) the strength of SOI is angle dependent and can be written as

\[
h_{so} = \sqrt{\alpha^2 + \beta_3^2 k_f} \sqrt{1 + \cos 2\psi \cos 2\theta + (2(\beta_3^2 - \frac{2\beta_3}{\lambda}) \sin(\psi + \pi/4)) (1 + \cos 4\theta) - \frac{4\beta_3}{\lambda} \cos(\psi + \pi/4) \cos 2\theta} \quad (A1)
\]

where \( \cos \psi = \lambda_1/\sqrt{\lambda_1^2 + \lambda_2^2} \).

First we consider the case for \( \beta_3 = 0 \). The Hamiltonian is written as

\[
H = \frac{k^2}{2m} + (\alpha + \beta) k_x \sigma_y - (\alpha - \beta) k_y \sigma_x,
\]

where \( k_x \) is along the [110] direction, \( \lambda_1 = \alpha + \beta \) and \( \lambda_2 = - (\alpha - \beta) \). The Green’s function for this Hamiltonian takes the form

\[
G^{R(A)} = \frac{E - \frac{k^2}{2m} \pm \frac{i}{\tau} + (\alpha + \beta) k_x \sigma_y - (\alpha - \beta) k_y \sigma_x}{(E - \frac{k^2}{2m} \pm \frac{i}{\tau} - (\alpha^2 + \beta^2) k^2 (1 + \frac{2\alpha\beta}{\alpha^2 + \beta^2} \cos 2\theta)}.
\]

\[
= \frac{E - \frac{k^2}{2m} \pm \frac{i}{\tau} + \lambda_1 k_x \sigma_y + \lambda_2 k_y \sigma_x}{(E - \frac{k^2}{2m} \pm \frac{i}{\tau} - \frac{\lambda_1^2 + \lambda_2^2}{2} k^2 (1 + \gamma \cos 2\theta)}, \quad (A3)
\]

where \( \tau \) is the momentum scattering time, \( \gamma = \frac{2\alpha\beta}{\alpha^2 + \beta^2} = \frac{\lambda_1^2 - \lambda_2^2}{\lambda_1^2 + \lambda_2^2} \). It is more convenient to write down the element of the \( 2 \times 2 \) Green’s function Eq. (A3) as

\[
G_{11} = G_{22} = \frac{1}{2} \left( \frac{1}{E - \frac{k^2}{2m} - \lambda k \sqrt{1 + \gamma \cos 2\theta} \pm \frac{i}{\tau}} + \frac{1}{E - \frac{k^2}{2m} + \lambda k \sqrt{1 + \gamma \cos 2\theta} \pm \frac{i}{\tau}} \right).
\]

\[
G_{12} = \frac{1}{2} \left( \frac{1}{E - \frac{k^2}{2m} - \lambda k \sqrt{1 + \gamma \cos 2\theta} \pm \frac{i}{\tau}} - \frac{1}{E - \frac{k^2}{2m} + \lambda k \sqrt{1 + \gamma \cos 2\theta} \pm \frac{i}{\tau}} \right) \sqrt{2(i \cos \psi \cos \theta + \sin \psi \sin \theta)} \sqrt{1 + \gamma \cos 2\theta} \quad (A4)
\]

\[
G_{21} = \frac{1}{2} \left( \frac{1}{E - \frac{k^2}{2m} - \lambda k \sqrt{1 + \gamma \cos 2\theta} \pm \frac{i}{\tau}} - \frac{1}{E - \frac{k^2}{2m} + \lambda k \sqrt{1 + \gamma \cos 2\theta} \pm \frac{i}{\tau}} \right) \sqrt{2(i \cos \psi \cos \theta + \sin \psi \sin \theta)} \sqrt{1 + \gamma \cos 2\theta}
\]

where \( \lambda = \sqrt{(\lambda_1^2 + \lambda_2^2)/2} = \sqrt{\alpha^2 + \beta^2}, \cos \psi = \lambda_1/\sqrt{\lambda_1^2 + \lambda_2^2} \) and \( \gamma = \cos 2\psi \).

According to Eq. (8), the diagonal element of the spin polarization along \( z \) direction has the form

\[
I^{zz} = I_{11,11} \equiv I_{11} - I_{22,11} + I_{22,22}
\]

\[
= \frac{1}{2m \tau} \int \frac{d^2k}{(2\pi)^2} (G_{11}^A G_{11}^R - G_{21}^A G_{21}^R - G_{12}^A G_{22}^R + G_{22}^A G_{22}^R).
\]

(A5)

The first term and the fourth term in Eq. (A8) are equal to each other and have the form

\[
= \frac{1}{16m \tau} \int_{0}^{2\pi} d\theta \left( k^+ \frac{k^+}{1 - i\Omega \tau} + k^- \frac{k^-}{1 - i\Omega \tau} + k^+ \frac{k^-}{1 - i\Omega \tau} + k^- \frac{k^-}{1 - i\Omega \tau} \right) \quad (A6)
\]
where \( v_f = \frac{2E_f}{md} \). In the polar coordinate, \( d^2k = \int d(k^2/2) d\theta \). As we assume that \( \lambda k_f \ll E_f \), \( d(k^2/2) \simeq mdE \) where \( m \) is the effective mass.

The other two terms are also equal to each other and can be written as

\[
\frac{1}{2m\tau} \int \frac{d^2k}{(2\pi)^2} G^A_{21} G^R_{12} = \int \frac{d^2k}{(2\pi)^2} \left( \frac{1}{E - \epsilon_+(k) - \frac{i}{2\tau_e}} - \frac{1}{E - \epsilon_-(k) - \frac{i}{2\tau_e}} \right) \times \frac{1}{\Omega} \frac{\partial E}{\partial k} \tau \cos 2\theta = \frac{1}{16m\pi} \int_0^{2\pi} d\theta \frac{1}{1 - i\Omega \tau} \left( \frac{k^+}{1 - i\Omega \tau + 2i\lambda k\sqrt{1 + \gamma \cos 2\theta}} - \frac{k^-}{1 - i\Omega \tau - 2i\lambda k\sqrt{1 + \gamma \cos 2\theta}} \right) + \frac{1}{1 - i\Omega \tau} \right). 
\]

(A7)

Substituting Eq. (A6) to Eq. (A8) we have

\[
I^{zz} = \frac{1}{4\pi} \int_0^{2\pi} d\theta \frac{1}{1 - i\Omega \tau + 2i\lambda k\sqrt{1 + \gamma \cos 2\theta}} + \frac{1}{1 - i\Omega \tau - 2i\lambda k\sqrt{1 + \gamma \cos 2\theta}}
\]

\[
= \frac{1}{2\pi} \int_0^{2\pi} d\theta \frac{1}{1 - i\Omega \tau} \left( \frac{1}{(1 - i\Omega \tau)^2 + (\Omega_{so} \tau)^2} \right) \int_0^\pi dx \left( 1 + a \cos(x) \right)
\]

(A8)

where \( x = 2\theta \) and \( a = \gamma(\Omega_{so} \tau)^2/(1 - i\Omega \tau)^2 + (\Omega_{so} \tau)^2) \). The indefinite integral \( \int dx \frac{1}{1 + a \cos(x)} = \frac{2 \text{arctanh} \left( \frac{-1 + a}{\sqrt{-1 + a^2}} \right)}{\sqrt{-1 + a^2}} \).

Therefore we have

\[
I^{zz} = \frac{1}{2\pi} \left( \frac{1}{1 - i\Omega \tau} \int_0^\pi dx \frac{2}{1 + a \cos(x)} \right)
\]

\[
= \frac{1}{2\pi} \left( \frac{1}{1 - i\Omega \tau} \right) \times 2 \text{arctanh} \left( \frac{-1 + a}{\sqrt{-1 + a^2}} \right) - \text{arctanh} \left( \frac{-1 + a}{\sqrt{-1 + a^2}} \right)
\]

\[
= \frac{1}{2\pi} \left( \frac{1}{1 - i\Omega \tau} \right) \times 2\pi i \sqrt{-1 + a^2} = \frac{1}{\sqrt{(1 - i\Omega \tau)^2 + (\Omega_{so} \tau)^2} - \gamma^2(\Omega_{so} \tau)^4}.
\]

(A9)

When Rashba SOI is zero, the strength of SOIs takes the form

\[
h_{so} = \beta_3 k_f \sqrt{1 + (2\beta_3^2/\beta_1^2 - 2\beta_4/\beta_1)(1 + \cos 4\theta)}.
\]

(A10)

To obtain the spin diffusive matrix element \( I^{zz} \), it is easy to prove that we only need to replace the term \( \lambda k\sqrt{1 + \gamma \cos 2\theta} \) in Eq. (A9) with \( h_{so} \) in Eq. (A10). Therefore, we have

\[
I^{zz} = \frac{1}{4\pi} \int \frac{2(1 - i\Omega \tau)}{(1 - i\Omega \tau)^2 + (2h_{so} \tau)^2})d\theta
\]

\[
= \frac{1}{\sqrt{(1 - i\Omega \tau)^2 + (\Omega_{so} \tau)^2} \sqrt{(1 - i\Omega \tau)^2 + (\Omega_{so} \tau)^2} \sqrt{(1 + 2(\beta_4/\beta_1)^2 - 2\beta_3/\beta_1)}}.
\]
