Summary

Hypothyroidism is a common medical condition and is often easily managed with excellent outcomes, when treated adequately. Compliance with levothyroxine (LT4) therapy is often compromised because of the need for a daily and lasting schedule. Overt rhabdomyolysis due to under-treatment or non-compliance is a rare occurrence. We report a case of rhabdomyolysis leading to acute kidney injury (AKI) on chronic kidney disease (CKD) requiring hemodialysis (HD) in a 68-year-old Caucasian male due to non-compliance with levothyroxine (LT4) therapy. Our patient ‘ran out of levothyroxine’ for approximately 4 weeks and developed gradually progressive muscle pain. The diagnosis of severe AKI due to rhabdomyolysis was made based on oliguria, elevated creatinine kinase (CK), and renal failure. Resuming the home dose of LT4 failed to correct CK levels, and there was a progressive decline in renal function. Although increasing doses of LT4 and three cycles of HD improved CK levels, they remained above baseline at the time of discharge. The patient recovered gradually and required HD for 4 weeks. CK levels normalized at 6 weeks. Through this case report, we highlight that non-compliance with LT4 therapy can lead to life-threatening complications such as renal failure and hence the need to educate patients on the significance of compliance with LT4 therapy should be addressed.

Learning points

• Non-compliance to levothyroxine therapy is common and can lead to serious complications, including rhabdomyolysis.
• Rhabdomyolysis is an uncommon presentation of hypothyroidism and severe rhabdomyolysis can result in renal failure requiring hemodialysis.
• Rhabdomyolysis associated with hypothyroidism can be further exacerbated by concomitant use of statins.

Background

Hypothyroidism is frequently associated with myalgias, muscle stiffness, easy fatigability, and occasionally some degree of myopathy with mildly elevated muscle enzymes. Rarely, hypothyroidism may be complicated by rhabdomyolysis, the rapid destruction of skeletal muscle with the release of myoglobin, creatine kinase, urate, and electrolytes into the circulation (1).

Although overt rhabdomyolysis in patients with hypothyroidism is a known complication, severe rhabdomyolysis leading to acute kidney injury (AKI) requiring hemodialysis (HD) is extremely rare. Factors that contribute to rhabdomyolysis in hypothyroidism include strenuous physical activity, medication non-compliance, and concomitant use of medications causing myopathy,
for example, statin and fibrates. Cases of rhabdomyolysis are reported in patients with undiagnosed hypothyroidism who take statins even without any precipitating factor; however, extreme creatine kinase (CK) elevation is extremely rare (1). Severe rhabdomyolysis and AKI can be potentially life-threatening due to the resultant metabolic derangements seen in these patients.

Medication non-adherence, in general, is a prevalent issue. The reported prevalence of medication non-compliance ranges from 25 to 50% (2). Contributing factors such as disease symptoms, patient demographics, insurance coverage, and psychosocial factors play a vital role. Levothyroxine (LT4) has poor absorption and needs to be taken on an empty stomach, which further exacerbates compliance. Once-weekly regimens have also been suggested and have been successfully used to achieve normal thyroid-stimulating hormone levels (TSH) in some patients (3). Nonetheless, non-compliance to LT4 therapy remains a frequently encountered problem in clinical practice. Here, we describe a case of rhabdomyolysis-induced severe AKI in chronic kidney disease (CKD) secondary to non-compliance to LT4 therapy.

Case presentation

A 68-year-old Caucasian male presented to the emergency room with a 2-week history of worsening fatigue and generalized weakness, accompanied by decreased urine output and bilateral lower extremities pain. Systematic physical was unremarkable except for nausea and reduced appetite. There was no history of recent physical exertion, prolonged immobilization, crush injury, electrical injury, traumatic injury, heat exposure, or seizures. The patient denied any use of alcohol or illicit drugs. A review of prior lab work-up (done 3 months ago) did not reveal hypokalemia, hypophosphatemia, or other electrolyte abnormalities. Past medical history was significant for coronary artery disease, heart failure with reduced ejection fraction, hypertension, dyslipidemia, primary hypothyroidism, type 2 diabetes mellitus, and chronic kidney disease stage 3A (attributed to underlying suspected diabetic and hypertensive nephropathy).

Home medications included aspirin 81 mg daily, levothyroxine 200 µg daily, metoprolol 25 mg daily, doxazosin 2 mg daily, amlodipine 5 mg daily, fosinopril 40 mg twice daily, metformin 500 mg twice daily, and rosuvastatin 40 mg daily. For LT4, the patient reported that ‘he ran out of it’ for a period of approximately 4 weeks and resumed it a few days before coming to the hospital (3–4 days). On presentation, he was hemodynamically stable with blood pressure 139/85 mmHg, temperature 97°F, respiratory rate 18 per minute, pulse rate 80 b.p.m., and oxygen saturation of 99% on room air. His BMI was 38.37 kg/m². Musculoskeletal examination revealed proximal muscle weakness with power 3/5 in bilateral lower extremities and mild tenderness of the thigh muscles. The remaining physical exam was unremarkable.

Investigation

Laboratory workup on admission showed elevated creatinine 13.1 mg/dL, blood urea nitrogen (BUN) 101 mg/dL, low eGFR of 4.0 mL/min/1.73 m², and elevated creatine kinase (CK) 69 500 U/L. Baseline creatinine was 1.4 mg/dL. Arterial blood gas (ABG) showed pH 7.256 and bicarbonate 13.4, suggestive of metabolic acidosis. Urine toxicology was negative. Work up for further evaluation of rhabdomyolysis revealed elevated TSH of 55.8 uIU/mL (0.45–4.5 uIU/mL) with free T4 0.61 ng/dL (0.8–1.8 ng/dL) suggestive of hypothyroidism. The rest of the laboratory studies are summarized in Table 1 and showed anemia, hyperkalemia, hyperphosphatemia, metabolic acidosis, transaminitis, and secondary hyperparathyroidism. A review of labs from previous workup (3 months ago) revealed normal thyroid function tests (TSH 1.6 uIU/mL and free T4 1.3 µg/dL) on LT4 200 µg and baseline CKD stage 3B (EGFR 51 mL/min/1.73 m² with baseline creatinine 1.4 mg/dL). Hence, the patient was diagnosed with severe rhabdomyolysis secondary to non-compliance with LT4 therapy in the presence of concurrent statin use, leading to AKI.

Treatment

Rosuvastatin, fosinopril, and metformin were stopped, and aggressive intravenous hydration was initiated. Sodium bicarbonate was used to address both metabolic acidosis and rhabdomyolysis. Sevelamer was used for hyperphosphatemia. The home dose of oral LT4 200 µg was reinitiated. Despite 2 days of aggressive treatment, the patient remained oliguric, CK remained elevated, and he started to have volume overload. Subsequently, on day 3, intermittent hemodialysis was initiated with a high flux Revaclear 300 filter. Because of persistently elevated CK levels, a decision was made to increase his LT4 dose to 250 µg daily. The patient underwent three sessions of HD during the course of his hospitalization.

Outcome and follow-up

On day 6, CK was still elevated (41 514 U/L), and there were no signs of renal recovery and hence outpatient dialysis.
was arranged. He was discharged home on aspirin 81 mg daily, insulin glargine 5 units at bedtime, levothyroxine 250 µg daily, metoprolol 25 mg daily, doxazosin 2 mg daily, and amlodipine 5 mg daily. The patient needed HD for 4 weeks. At 6 weeks follow-up, his laboratory workup revealed CK 105 U/L, TSH 6.6 uIU/mL, free T4 0.94 ng/dL, creatinine 1.42 mg/dL and eGFR 54 mL/min/1.73 m².

### Discussion

Hypothyroidism is a common and well-known medical condition with a prevalence of 3.7% (1999–2002) (4). It has a broad spectrum of clinical presentations including, but not limited to, fatigue, cold intolerance, bradycardia, constipation, menstrual irregularities, and dry skin. Rarely, hypothyroidism can lead to muscle damage, ranging from asymptomatic elevations of the CK level to significant rhabdomyolysis. Thyroid myopathy is a well-recognized but poorly understood complication of hypothyroidism. The pathophysiology of rhabdomyolysis is believed to be due to inhibition of mitochondrial oxidative phosphorylation resulting in decreased ATP production and dysregulation of multiple biochemical pathways. Studies have also suggested changes in muscle fibers from fast twitching to slow twitching, deposition of glycosaminoglycans, poor contractility of actin-myosin units, low myosin ATPase activity or low ATP turnover in the skeletal muscles (5). There is lack of any clear correlation between the severity of hypothyroidism and CK levels. Hence, hypothyroidism is a crucial differential when evaluating unexplained CK elevations.

Rhabdomyolysis is typically defined by elevated CK level, at least five times above the upper limit of normal, and is usually greater than 5000 international units/L. In our patient, CK was massively elevated to more than 350 times the upper limit of normal. We believe that concomitant use of statin in our patient might have resulted in a higher degree of myopathy (6). Additionally, the use of other nephrotoxic drugs in our patient, such as metformin and fosinopril, might have exacerbated the impact of rhabdomyolysis, leading to rapid deterioration of AKI to end-stage renal disease and overt acidosis.

Rhabdomyolysis leads to the release of a heme-containing protein, myoglobin, into circulation. Multiple mechanisms are responsible for myoglobin-induced renal injury. It is toxic to renal tubules and causes renal vasoconstriction and the formation of tubular casts. However, myoglobin has poor sensitivity to the diagnosis of rhabdomyolysis. Elevated CK levels are considered the most sensitive marker. The frequency of AKI in patients with rhabdomyolysis ranges from 15 to 50% and is directly associated with the degree of CK elevation (7). AKI due to rhabdomyolysis can be worsened by associated dehydration. Initial management of rhabdomyolysis consists of intravenous fluids administration and correction of any electrolyte abnormalities. Despite adequate intravenous hydration and discontinuation of statins, our patient continued to have deterioration in renal function and once thyroid function tests revealed hypothyroidism, thyroid hormone replacement was reinitiated. Unfortunately, our patient's renal function continued to deteriorate further, necessitating the initiation of HD.

Management of hypothyroidism requires life-long LT4 therapy. However, as with any other chronic condition, adherence to medical management is common. Current literature suggests that up to 50% of the patients may have poor compliance to medications, which is attributed to several underlying factors (8). Although patients in clinical trials tend to have better medication adherence, this can be significantly misleading as only an average adherence rate is reported among patients with chronic disease. Furthermore, a Cochrane database analysis assessed that interventions to enhance patient adherence

### Table 1  Laboratory results on admission.

| Laboratory test | Level | Reference range |
|-----------------|-------|-----------------|
| WBCs | 8.4 k/µL | 3.7–10.3 k/µL |
| RBCs | 3.270 M/µL | 3.5–5.2 M/µL |
| Hemoglobin | 9.7 g/dL | 11.2–15.7 g/dL |
| Hematocrit | 28.7% | 34–45% |
| Platelets | 189 k/µL | 155–369 k/µL |
| Glucose | 93 mg/dL | 74–90 mg/dL |
| Sodium | 133 mmol/L | 136–145 mmol/L |
| Potassium | 5.5 mmol/L | 3.7–4.8 mmol/L |
| Bicarbonate | 17 mmol/L | 22–29 mmol/L |
| Chloride | 101 mmol/L | 97–107 mmol/L |
| Calcium | 8.5 mg/dL | 8.9–10.2 mg/dL |
| Magnesium | 2.8 mg/dL | 1.9–2.4 mg/dL |
| Phosphorus | 7.6 mg/dL | 2.5–4.5 mg/dL |
| Albumin | 3.5 g/dL | 3.3–4.6 g/dL |
| Blood urea nitrogen | 101 mg/dL | 0–30 mg/dL |
| Creatinine | 13.10 mg/dL | 0.60–1.10 mg/dL |
| Estimated GFR | 4.0 mL/min/1.73 m² | >60 mL/min/1.73 m² |
| Aspartate transaminase | 1693 U/L | 9–36 U/L |
| Alanine transaminase | 386 U/L | 8–33 U/L |
| Alkaline phosphatase | 147 U/L | 46–142 U/L |
| Total protein | 7.5 g/dL | 6.3–7.9 g/dL |
| Parathyroid hormone | 342 pg/mL | 15–65 pg/mL |
| Vitamin D total | 29.6 ng/mL | 30.0–100 ng/mL |
| Thyroid stimulating hormone (TSH) | 55.800 uIU/mL | 0.358–3.740 uIU/mL |
| Free thyroxine (FT4) | 0.61 ng/dL | 0.8–1.8 ng/dL |
| Total thyroxine (TT4) | 4.0 µg/dL | 4.8–13.9 µg/dL |
| Total T3 (TT3) | 27 ng/dL | 71–180 ng/dL |
| Hepatitis panel | Negative | |
to prescribed medications did not show any improvement (9). Persistently elevated TSH levels despite the patient’s reported use of LT4 suggest poor adherence to LT4. In these cases, poor absorption must be differentiated from non-compliance by administering a weight-based weekly oral dose of LT4 and measurement of free T4 at baseline and 2 h (thyroxine absorption test). Adequate free T4 levels among patients with poor compliance rules out any malabsorption syndrome (10). In our case, the thyroxine absorption test was not done as the patient admitted to non-compliance. Occasionally, in some patients with poor compliance, a once-weekly dose of LT4 is administered (3).

In summary, in our patient, non-compliance with LT4 therapy was likely the principal etiology of rhabdomyolysis induced AKI. An extreme elevation in CK levels can be attributed to the concomitant use of statin. The insidious development of such CK levels and AKI highlight the overt presentation of rhabdomyolysis in hypothyroidism and the importance of medication compliance. Healthcare workers should be aware of this rare side effect of hypothyroidism. They must always explore non-compliance with LT4 therapy among patients on chronic LT4 replacement. Hence, our case highlights the importance of screening for medication non-compliance in patients with hypothyroidism presenting with rhabdomyolysis and AKI.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research reported.

Funding
Funding for this case report was provided by the Education Department of Pikeville Medical Center, Pikeville, KY, USA.

Patient consent
Written informed consent was obtained from the patient for the publication of the submitted article.

Author contribution statement
CP was the patient’s nephrologist and was directly involved in the patient’s care. AG and QE were part of the treatment team, performed literature overview, and wrote the manuscript. RR was the supervising provider and was directly involved in writing the manuscript and literature review. All providers had direct permission of CP, the primary physician responsible for the patient.
