Abstract. The Greenhouse Gases Observing Satellite (GOSAT) was launched in 2009 to measure global atmospheric CO₂ and CH₄ concentrations. GOSAT is equipped with two sensors: the thermal and near-infrared sensor for carbon observation (TANSO)-Fourier transform spectrometer (FTS) and TANSO-cloud and aerosol imager (CAI). The presence of clouds in the instantaneous field of view of the FTS leads to incorrect estimates of the concentrations. Thus, the FTS data suspected to have cloud contamination must be identified by a CAI cloud discrimination algorithm and rejected. Conversely, overestimating clouds reduces the amount of FTS data that can be used to estimate greenhouse gases concentrations. This is a serious problem in tropical rainforest regions, such as the Amazon, where the amount of useable FTS data is small because of cloud cover. Preparations are continuing for the launch of the GOSAT-2 in fiscal year 2018. To improve the accuracy of the estimates of greenhouse gases concentrations, we need to refine the existing CAI cloud discrimination algorithm: Cloud and Aerosol Unbiased Decision Intellectual Algorithm (CLAUDIA1). A new cloud discrimination algorithm using a support vector machine (CLAUDIA3) was developed and presented in another paper. Visual inspection can use the locally optimized standards for judging, although CLAUDIA1 and CLAUDIA3 use common thresholds all over the world. Thus, the accuracy of visual inspection is better than that of these algorithms in most regions, with the exception of snow and ice covered surfaces, where there is not enough spectral contrast to distinguish cloud. For the reason visual inspection can be used for the truth metric for the verification exercise. In this study, we compared between CLAUDIA1-CAI and CLAUDIA3-CAI for various land cover types, and evaluated the accuracy of CLAUDIA3-CAI by comparing the both of CLAUDIA1-CAI and CLAUDIA3-CAI against visual inspection of the same CAI images in tropical rainforests. Comparative results between CLAUDIA1-CAI and CLAUDIA3-CAI for various land cover types indicated that CLAUDIA3-CAI had tendency to identify bright surface and optically thin clouds, however, misjudge the edges of clouds as compared with CLAUDIA1-CAI. The accuracy of CLAUDIA3-CAI was approximately 89.5 % in tropical rainforests, which is greater than that of CLAUDIA1-CAI (85.9 %) for the test cases presented here.

Funding. This research is supported by the GOSAT-2 Project at the National Institute for Environmental Studies (NIES), Japan (2015, 2016); and based on results obtained as part of a project commissioned by the New Energy and Industrial Technology Development Organization (NEDO). NIES and NEDO had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript, and in the decision to publish the results.

1 Introduction

Greenhouse Gases Observing Satellite (GOSAT) was launched in 2009 to measure global atmospheric CO₂ and CH₄ concentrations. Preparations are continuing for the launch of its successor, GOSAT-2, in fiscal year 2018. The missions of GOSAT-2 are as follows: to continue and improve the satellite measurements of major greenhouse gases performed by GOSAT; to monitor the effects of climate change and human activities on the carbon cycle; and to contribute to climate science and climate change related policies (NIES GOSAT-2 Project, 2014). These policies include Reducing Emissions from Deforestation and forest Degradation and the role of conservation, sustainable management of forests and enhancement of forest carbon stocks in developing countries (REDD+), and the Joint Crediting Mechanism (JCM), which was proposed by the Japanese government to facilitate the diffusion of leading low-carbon technologies, products, systems, services, and infrastructure in developing countries (Ministry of the Environment, Japan, 2015). Monthly regional CO₂ fluxes are estimated from the column-averaged dry air mole fractions of CO₂ (XCO₂) retrieved from spectral observations made by GOSAT (Maksyutov et al., 2013). The result is publicly available as the L4A CO₂ product (Maksyutov et al., 2014). The expected role of the CO₂ fluxes estimated from the GOSAT data is the system for measurement, reporting and verification (MRV) of CO₂ fluxes estimated from forest inventory data. Currently, the uncertainty of the L4A CO₂ product is about 0.9 Gt-C/region/year in the Amazon (L4A CO₂ product V02.03 in region ln 09-12, 2009-2012). Thus, total net CO₂ flux from deforestation for the period 2000–2010 in tropical America was estimated to be 0.56 Gt-C/year (Baccini et al., 2012). Accuracy 16 times higher than at present is required assuming that the MRV for REDD+ and JCM needs an accuracy of 10%.

GOSAT is equipped with two sensors: the Thermal and Near-infrared Sensor for Carbon Observation (TANSO)-Fourier Transform Spectrometer (FTS) and TANSO-Cloud and Aerosol Imager (CAI) (Table 1). The presence of clouds in the instantaneous field of view of the FTS leads to incorrect estimates of greenhouse gas concentrations (Uchino et al., 2012). To solve the problem, the FTS data suspected to have cloud contamination must be identified by the Cloud and Aerosol Unbiased Decision Intellectual Algorithm used with CAI (CLAUDIA1-CAI) (Ishida and Nakajima, 2009) and rejected. The cloud information is publicly available as the CAI L2 cloud flag product. However, CAI does not have a thermal infrared band. In general, cirrus cloud is identified by using multiple thermal infrared bands, which include water vapour absorption
bands (Ishida et al., 2011a). Meanwhile, the FTS has a 2 μm band that contains many strong water vapour absorption bands. Moreover, the CAI L2 cloud flag product may not be sensitive enough to detect clouds of sub-pixel size in ocean observations. To cope with these difficulties, the FTS data suspected to have cloud contamination are identified by two additional tests: the 2 μm band test and the CAI coherent test (Yoshida et al., 2010). Conversely, overestimation of clouds reduces the amount of the FTS data that can be used to estimate greenhouse gas concentrations. This is a serious problem in tropical rainforest regions, such as the Amazon, where there is a small amount of suitable FTS data (approximately 3 % of the number of observations) because of cloud cover (Figs. 1, 2). For the reason we need to optimize thresholds between cloud and clear-sky because there are tradeoffs in maximizing accuracy while minimizing overlook and overestimate. To solve the problem, a new cloud discrimination algorithm (CLAUDIA3) using a support vector machine (SVM) (Vapnik and Lerner, 1963) was developed (Ishida et al., 2018). CLAUDIA3 can automatically identify the optimized thresholds only using obvious clear-sky training data although CLAUDIA1 needs to optimize thresholds in manually. Verification was also performed by comparing with the MODIS cloud mask algorithm (Ackerman et al., 2010) and ceilometer data provided by Atmospheric Radiation Measurement (ARM) (Mather and Voyles, 2013) in the paper (Ishida et al., 2018). Furthermore the impact of different Support Vector generation procedures on cloud discrimination using CLAUDIA3 has also been evaluated in a previous study (Oishi et al., 2017).

Table 1: Specifications of CAI.

|        | Band 1 | Band 2 | Band 3 | Band 4 |
|--------|--------|--------|--------|--------|
|       | Spectral coverage | NUV | Red | NIR | SWIR |
| (μm)  | 0.370-0.390 | 0.664-0.684 | 0.860-0.880 | 1.56-1.65 |
| Swath (km) | 1000 | 1000 | 1000 | 750 |
| Spatial resolution | 500 | 500 | 500 | 1500 |
Figure 1: Monthly changes in the number of FTS L2 XCO₂ data in the Amazon. The five-point cross track scan mode was used until 1 August 2010, when it was replaced with the three-point cross track scan mode. Therefore the numbers themselves before and after 1 August 2010 cannot be compared. (single column)

Figure 2: Clear-sky probability at 0.1° × 0.1° calculated with MYD35_L2. There are low clear-sky probabilities over most tropical rainforests because the moisture helps create clouds. (single column)

The accuracy of CLAUDIA1-CAI was evaluated by comparing it with the MODIS/Aqua cloud mask data product (MYD35) (Ackerman et al., 2010) because the MODIS cloud mask algorithm uses a larger number of bands for cloud
discrimination than CLAUDIA1-CAI, and CLAUDIA1 was developed based on the MODIS cloud mask algorithm (Taylor et al., 2012; Ishida et al., 2011b). However, these comparisons cannot identify common weak points in the algorithms and another verification method is required. Visual inspection can use locally optimized standards for judging, whereas CLAUDIA1 and CLAUDIA3 use the common thresholds globally. Thus, the accuracy of visual inspection is better than that of these algorithms in most regions, with the exception of snow and ice covered surfaces, where there is not enough spectral contrast to distinguish cloud. For the reason visual inspection can be used for the truth metric for the verification exercise. Therefore, the accuracy of CLAUDIA1-CAI also has been evaluated by visual inspection in tropical rain forests (Oishi et al., 2014). In this study, we deal with the application of the CLAUDIA3 to GOSAT CAI data. And then, we compare between CLAUDIA1-CAI and CLAUDIA3-CAI for various land cover types, and evaluate the accuracy of CLAUDIA3-CAI by comparing the both of CLAUDIA1-CAI and CLAUDIA3-CAI against visual inspection of the same CAI images in tropical rainforests.

2 Materials and Methods

2.1 Study area and data

The study area for various land cover types is the same as the previous study (Oishi et al., 2017) (Fig. 3). The total forest area in the Amazon, Congo, and Southeast Asia rainforest basins is over 13 million km², which corresponds to one-third of the total global forest area (FAO and ITTO, 2011). The three most forest-rich countries (Brazil, Democratic Republic of Congo, and Indonesia) account for 57% of the total global forest area (FAO and ITTO, 2011). However, the total net emissions of carbon from tropical deforestation and land use were estimated to be 1.0 Pg-C/yr in the three rainforest basins (Baccini et al., 2012). In particular, Brazil and Indonesia have by far the highest and second highest deforestation rates, respectively (Fig. 4). Therefore, the study area for rainforests is Borneo and the Amazon (Fig. 5).

GOSAT returns to a similar footprint after 44 orbits (44 CAI paths) in three days. The satellite ground path of one orbit is divided into 60 equidistant CAI frames. We used the GOSAT CAI L1B product, which general users could download from the GOSAT User Interface Gateway (GUIG, https://data.gosat.nies.go.jp), for various land cover types on the beginning of the month from 2012 to 2014 in the same as the previous study (Oishi et al., 2017) (Table 2), and for rainforests (Table 3). Currently GUIG has been changed to GOSAT Data Archive Service (GDAS, https://data2.gosat.nies.go.jp/index_en.html). The spatial resolution of these products (pixel size at nadir) is 500 m, the image size is 2048 × 1355 pixels (approximately 1000 × 680 km). The CLAUDIA algorithm requires a land/sea mask and a surface albedo data. The CAI L1B product includes the Shuttle Radar Topography Mission’s 15° land/sea mask. For areas with latitudes higher than ±60°, the USGS Global Land 1-KM AVHRR Project mask is used. Surface albedo data at 1/30° resolution was generated from the CAI L1B data from 10 recurrent cycles by separating the land and water regions. This processing consists of three steps (Ishihara and Nobuta, 2013): (1) calculate the minimum reflectance to remove cloud-contaminated pixels; (2) cloud shadow correction (Fukuda et al., 2013); and (3) atmospheric correction.

2.2 CLAUDIA1

CLAUDIA1-CAI comprises the calculation of clear-sky confidence levels (CCL) for every threshold test and their comprehensive integration (Ishida and Nakajima, 2009). Integrated-CCL of 0 means that the pixel is cloudy and 1 means that the pixel is cloud-free. Ambiguous pixels between cloudy and cloud-free are described by numerical values from 0 to 1. The threshold below which the integrated-CCL counts the pixel as cloud-free for GOSAT FTS L2 is 0.33, otherwise the pixel is regarded as cloudy (Yoshida et al., 2010). The flow of the algorithm is shown in Fig. 6.
2.3 New cloud discrimination algorithm (CLAUDIA3)

CLAUDIA1 performs cloud discrimination by using thresholds set based on experience. The new cloud discrimination algorithm (CLAUDIA3, Ishida et al., 2018) uses SVM to decide the thresholds objectively by using multivariate analysis. SVM is a supervised pattern recognition method. First, it determines the following items using training samples of typical clear and cloudy pixels: 1) a decision function to discriminate between two classifications (clear and cloudy), 2) the thresholds, and 3) the support vectors, which are training samples specified by the decision function. The support vectors are decided in a high-dimensional feature space of the training samples. Next, it performs cloud discrimination by using the decision function, thresholds, and support vectors it determined. CLAUDIA3 applies the kernel trick (Boser et al., 1992) to soft-margin SVM (Cortes and Vapnik, 1995). The kernel uses a second-order polynomial (Eq. (1))

\[ K(x_i, x) = \frac{(x_i \cdot x + 1)^2}{2}, \]  

(1)

where \( K \) is the kernel function, \( x_i \) is the support vectors, and \( x \) is input data. The flow of CLAUDIA3-CAI is explained in Fig. 7. For CLAUDIA3-CAI, an integrated-CCL of 0.5 corresponds to the separating hyperplane of clear support vectors and cloudy support vectors. In this study, we used two kinds of support vector: (1) support vectors generated by using MODIS data in February for cloud discrimination between November and April, and (2) support vectors generated by using MODIS data in August for cloud discrimination between May and October based on a previous study (Oishi et al., 2017).
5 2.4 Analysis procedure for rainforests

The analysis procedure consists of the following steps (Fig. 8).

1) Cut 400 × 400 pixels around the centre of CAI L1B images.
2) Perform visual inspection of the pixels cut from the CAI L1B images.
   We performed a visual inspection of the presence or absence of clouds in every pixel.
3) Perform cloud discrimination by using CLAUDIA1-CAI and CLAUDIA3-CAI.
   For CLAUDIA1-CAI, we produced output images setting the integrated-CCL threshold to 0.33. For CLAUDIA3-CAI, we produced output images setting the integrated-CCL threshold to 0.5.
4) Compare output with visual inspection. We coloured the images by comparing the visual inspection images with the output images pixel-by-pixel.

![Image](image.png)

Figure 8: Analysis procedure. (a) CAI L1B image. (b) Visual inspection image of CAI L1B. (c) Output image from CLAUDIA1-CAI (CAI L2 cloud flag product) or CLAUDIA3-CAI. Pixels that are determined as cloudy are black. (d) Comparison of the visual inspection image and the output image. Pixels that are determined as cloudy in both are white. Pixels that are determined as clear in both are blue. Pixels that are determined as cloudy in the output image and clear in the visual inspection image are green. Unusual pixels that are determined as clear in the output image and cloudy in the visual inspection image are red. (2 column)

3 Results

In this study, “accuracy” is defined as the ratio of the number of pixels for which the standard image and output from the cloud discrimination algorithm agree to the total number of pixels in the input image. “Overlook” is defined as the ratio of the number of pixels judged clear in the output and cloudy in the standard image to the number of pixels that were judged cloudy in the standard image. “Overestimate” is defined as the ratio of the number of pixels judged cloudy in the output and
clear in the standard image to the number of pixels judged clear in the standard image. These definitions are written as follows.

\[
\text{Accuracy} = \frac{\text{Both cloudy} + \text{Both clear}}{\text{Total number of pixels}},
\]

\[
\text{Overlook} = \frac{\text{Clear despite cloudy}}{\text{Both cloudy} + \text{Clear despite cloudy}},
\]

\[
\text{Overestimate} = \frac{\text{Cloudy despite clear}}{\text{Both clear} + \text{Cloudy despite clear}}.
\]

3.1 Results for various land cover types

Figure 9 shows the monthly average accuracy, overlook, and overestimate for an integrated-CCL threshold of 0.33 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI. We used the CLAUDIA1-CAI result as the standard image.

In Australia and Algeria, Overlook was greater than Overestimate; there was tendency that CLAUDIA3-CAI judged clear, despite CLAUDIA1-CAI judged cloudy.

In Japan, Borneo, Canada, and Alaska, Overestimate was greater than Overlook; there was tendency that CLAUDIA3-CAI judged cloudy, despite CLAUDIA1-CAI judged clear.

In Thailand and Mongolia, there was seasonal variation. In Thailand, Overlook was greater than Overestimate from March to May, and Overestimate was greater than Overlook from June to February. In Mongolia, Overestimate was greater than Overlook from February to March, and Overlook was greater than Overestimate from April to January.

Figure 10 compares the output images of CLAUDIA1-CAI and CLAUDIA3-CAI for select cases in each region.

In Australia and Algeria, CLAUDIA3-CAI could identify bright surfaces, however, there were a few oversights of the edges of clouds.

In Japan, CLAUDIA3-CAI misjudged vegetation areas as clouds.

In Borneo, CLAUDIA3-CAI could identify optically thin clouds.

In Canada and Alaska, they were snow or ice covered scenes. Since the CAI is not equipped with any thermal infrared bands, cloud discrimination based on the temperature at the top of clouds is not feasible. Accordingly, it is difficult to discriminate between ice or snow and clouds. The difference or coincidence between CLAUDIA1-CAI and CLAUDIA3-CAI was attributed to this source of error.

In Thailand, CLAUDIA3-CAI could judge smokes as non-clouds, despite CLAUDIA1-CAI judged clouds, however, there were oversights of optically thin clouds and the edges of clouds on 3 April 2013. Furthermore CLAUDIA3-CAI misjudged clear muddy rivers and boundaries between land and water as cloudy. This was also reported about CLAUDIA1-CAI in previous study (Oishi et al. 2014). Conversely, CLAUDIA3-CAI could identify optically thin clouds on 2 September 2012.
In Mongolia, it was snow covered scene on 3 February 2013 in the same as Canada and Alaska. On the other hand, CLAUDIA3-CAI could identify bright surface, however, there were a few oversights of the edges of clouds on 2 June 2012.
Figure 9: Monthly average accuracy, overlook, and overestimate for various land cover types. Blue line indicates “Accuracy”, red line indicates “Overlook”, and green line indicates “Overestimate”. (2 column)

Figure 10: CAI L1B images (R: Band 2, G: Band 3, B: Band 1) and comparative results of CLAUDIA1-CAI and CLAUDIA3-CAI for various land cover types. (2 column)
3.2 Results in the Amazon

Figure 11 compares the visual inspection images and the output images for four select cases in the Amazon: low cloud cover, high cloud cover, small scattered clouds, and optically thin clouds. We used the visual inspection result as the standard image.

CLAUDIA3-CAI produced fewer overlooked clouds but slightly more overestimated clouds than CLAUDIA1-CAI did. CLAUDIA3-CAI misjudged clear muddy rivers on 23 August 2011 in CAI Path 29, Frame 32 and the surroundings of clouds on 1 April 2011 in CAI Path 29, Frame 32. The maximum accuracy values of CLAUDIA3-CAI and the CLAUDIA1-CAI occur at different integrated-CCL values with the thresholds for the Amazon. Fig. 12 shows the average accuracy, overlook, and overestimate of all the data in the Amazon for all 19 cases. These results indicate that the most suitable integrated-CCL thresholds are 0.75 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI in the Amazon. Since curved lines of overestimate and overlook intersect, CLAUDIA3-CAI can appropriately determine the boundary between cloud and clear-sky.
Figure 11: Comparison of the visual inspection images and the output images in the Amazon. Orange circles indicate the maximum accuracy values. Orange dotted lines indicate the integrated-CCL thresholds. Blue line indicates “Accuracy”, red line indicates “Overlook”, and green line indicates “Overestimate”. (2 column)
Figure 12: Average accuracy, overlook, and overestimate for all data for the Amazon. The most suitable integrated-CCL thresholds are 0.75 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI in the Amazon. (single column)

Table 4 shows the results for an integrated-CCL threshold of 0.33 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI, and Table 5 shows the results for an integrated-CCL threshold of the maximum accuracy values in Fig. 12 (CLAUDIA1-CAI: 0.75, CLAUDIA3-CAI: 0.5). There was no notable change in the accuracies with the season or location. When the integrated-CCL threshold was 0.33 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI, the accuracies were 87.0 % and 92.0 %, respectively. When the accuracy of CLAUDIA1-CAI was higher than that of CLAUDIA3-CAI, optically thick clouds covered a wide area of the input images. Furthermore, when the integrated-CCL threshold was 0.75 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI, the accuracy was the highest, at 88.3 % and 92.0 %, respectively. In the both cases, the accuracy of CLAUDIA3-CAI was higher than that of CLAUDIA1-CAI.

Table 4: Results for integrated-CCL thresholds of 0.33 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI in the Amazon.

| Date   | Location | Accuracy (%) | Overlook (%) | Overestimate (%) |
|--------|----------|--------------|--------------|------------------|

Table 5: Results for integrated-CCL thresholds of the maximum accuracy values in Fig. 11 (CLAUDIA1-CAI: 0.75, CLAUDIA3-CAI: 0.5) in the Amazon.
3.3 Results in Borneo

Figure 13 compares the results of the visual inspection images and the output images for two select cases in Borneo: small scattered clouds and optically thin clouds. We used the visual inspection result as the standard image. The comparison of the results for Borneo is similar to that for the Amazon. Figure 14 shows the average accuracy, overlook, and overestimate of all data for all cases in Borneo. These results indicate that the most suitable integrated-CCL thresholds are 0.85 for the CLAUDIA1-CAI and 0.35 for CLAUDIA3-CAI in Borneo. Since curved lines of overestimate and overlook intersect as same as the Amazon cases, CLAUDIA3-CAI can appropriately determine the boundary between cloud and clear-sky.
Figure 13: Comparison of the visual inspection images and the output images in Borneo. Orange circles indicate the maximum accuracy values. Orange dotted lines indicate the integrated-CCL thresholds. Blue line indicates “Accuracy”, red line indicates “Overlook, and green line indicates “Overestimate”. (2 column)

Figure 14: Average accuracy, overlook, and overestimate for all data for Borneo. The most suitable integrated-CCL thresholds are 0.85 for CLAUDIA1-CAI and 0.35 for CLAUDIA3-CAI in Borneo. (single column)

Table 6 shows the results for an integrated-CCL threshold of 0.33 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI, and Table 7 shows the results for an integrated-CCL threshold of the maximum accuracy values in Fig. 14 (CLAUDIA1-CAI: 0.85, CLAUDIA3-CAI: 0.35). There was no notable change in the accuracies with the season or location, similar to the results for the Amazon. For an integrated-CCL threshold of 0.33 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI, the accuracy was 84.8 % and 86.9 %, respectively. Furthermore, for an integrated-CCL threshold of 0.85 for CLAUDIA1-CAI
and 0.35 for CLAUDIA3-CAI, the highest accuracies of 87.5 % and 88.8 %, respectively, were obtained. In both cases, the accuracy of CLAUDIA3-CAI was greater than that of CLAUDIA1-CAI.

Table 6: Results for integrated-CCL thresholds of 0.33 for CLAUDIA1-CAI and 0.5 for CLAUDIA3-CAI in Borneo.

4 Discussions and conclusions

Comparative results between CLAUDIA1-CAI and CLAUDIA3-CAI for various land cover types indicated that CLAUDIA3-CAI had a tendency to identify bright surfaces and optically thin clouds, however, misjudge the edges of clouds as compared with CLAUDIA1-CAI. There are tradeoffs in maximizing accuracy while minimizing overlook and overestimate. Thus, it is sufficient to change the integrated-CCL threshold according to purpose. Furthermore, CLAUDIA3-CAI misjudged vegetation areas as clouds in Japan. It is necessary to add clear training data of Japanese vegetation areas for CLAUDIA3.

The averaged accuracy of CLAUDIA3 used with GOSAT CAI data (CLAUDIA3-CAI) was approximately 89.5% in tropical rainforests, which was greater than that of CLAUDIA1-CAI (85.9%) for the test cases presented here. This is mainly because, in contrast to CLAUDIA1-CAI, CLAUDIA3-CAI can detect optically thin clouds and the edges of clouds, which prevents cloud-contaminated FTS-2 data from being processed as cloud-free FTS-2 data in the greenhouse gas concentration calculations. However, CLAUDIA3-CAI tends to overestimate the surroundings of clouds, which are judged to be cloudy despite being clear. Thus, CLAUDIA3-CAI is not expected to increase the amount of the FTS-2 data that can be used to estimate greenhouse gas concentrations in tropical rainforests. Conversely, CLAUDIA3-CAI may be able to detect optically thin clouds that cannot be detected by visual inspection.

CLAUDIA3-CAI misjudged clear muddy rivers and boundaries between land and water as cloudy in the same manner as CLAUDIA1-CAI. This has three possible causes: (1) insufficient training data for muddy rivers to distinguish the differences in the spectral reflectance properties of muddy water and other water; (2) deviation of the positions in each CAI band owing to the band-to-band registration error; and (3) insufficient resolution of the surface albedo data. The surface albedo data was generated at 1/8° resolution by separating the land and water region. If the border pixels between land and water regions were mixed pixels, the albedo data of 1/8° areas that include the mixed pixels would be included. To decrease this effect, higher resolution surface albedo data are needed. For boundaries between land and water, the resolution of surface albedo...
data is being investigated because it may be the main problem; the misjudged regions and grid pattern of albedo data match. CLAUDIA3-CAI is more sensitive to differences between land and water than CLAUDIA1-CAI because there is a large difference in the structure of support vectors between land and water. However, generating higher resolution surface albedo data from CAI L1B data for 10 recurrent cycles cannot completely remove clouds in the minimum reflectance calculation. To solve this, initially we need to confirm whether 500 m resolution albedo data should be used. If necessary, we will develop a new method for generating surface albedo data. For example, simple cloud discrimination could be added to calculate the minimum reflectance, and if it is a cloud-contaminated pixel then the pixel is replaced by a minimum reflectance pixel, which is calculated from the same month in several years.

Although we used MODIS data as training images to generate support vectors in this study, the MODIS data and CAI data depend on observation conditions. In future work, we will use CAI data as training images to perform cloud discrimination for CAI data. Furthermore, we will verify CLAUDIA3-CAI by using global CAI data with an alternative method. For instance, comparison with satellite LiDAR data, such as CALIPSO, because it is impossible to perform visual inspection of global data and visual inspection is also not itself perfect. Addressing these points will make CLAUDIA3-CAI more reliable for GOSAT-2 CAI-2 cloud discrimination.

Author Contributions. Yu Oishi, Haruma Ishida, Takashi Y. Nakajima, Ryosuke Nakamura, and Tsuneo Matsunaga conceived and designed the studies; Yu Oishi performed evaluations and analyzed the data; Haruma Ishida contributed analysis tools; Yu Oishi wrote the paper.

Competing interests. The authors declare no conflict of interest. The founding sponsors had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript, and in the decision to publish the results.

Acknowledgements. This research is supported by the GOSAT-2 Project at the National Institute for Environmental Studies (NIES), Japan (2015, 2016); and the New Energy and Industrial Technology Development Organization (NEDO). The authors would like to thank the GOSAT Project, GOSAT-2 Project, and Dr. T. Endo for their helpful comments; Mr. T. Hirose for his assistance with visual inspection. We appreciate an anonymous reviewer who gave useful comments to the manuscript of the previous version.
