(August 12, 1997)

We argue that the self/anti-self charge conjugate states of the $(1/2, 0) \oplus (0, 1/2)$ representation possess the axial charge. Furthermore, we analyze the recent claims of the $\sim \sigma \cdot [A \times A^*]$ interaction terms for ‘fermions’. Finally, we briefly discuss the problem in the $(1, 0) \oplus (0, 1)$ representation.

11.30.Er, 12.60.-i, 14.60.St

I. INTRODUCTION

The Dirac equation and the relevant theory of charged particles do not admit the $\gamma^5$ chiral transformation. The sign in the mass term in the Lagrangian is reversed under this type of transformations. In the mean time, the chiral transformations play significant role in our understandings of the nature of weak and strong interactions, in the problem of (un)existence of monopoles as well. Many attempts have earlier been done in order to understand the origin of the chiral (a)symmetry from the first principles, see, e. g., [1]. Recently, the authors of ref. [2] proposed a very interesting model of the $m$-deformed non-local chiral transformations. But, they indicated at the importance of further study of chiral transformations and their relevance to the modern physics. These matters appear to be of use not only from the viewpoint of the construction of the fundamental theory for neutral particles (which is our primary purpose), but the consideration of constructs which admit the chiral invariance may also be useful for deeper understanding processes in QCD and other modern gauge models.

In the present article we prove that massive self/anti-self charge conjugate states in the $(1/2, 0) \oplus (0, 1/2)$ representation possess the axial charge (cf. also the McLennan-Case reformulation [3] of the Majorana theory [4], refs. [4, 7] and earlier papers [8, 9]). Furthermore, we present explicit examples which are relevant to the viewpoints of M. Markov [10], S. Weinberg [11] and P. A. M. Dirac [12] about the possibility of different equations for describing particles of some representation of the Lorentz group (particularly, of the $(1/2, 0) \oplus (0, 1/2)$ representation). In the most comprehensive and clear form it is expressed in the book, papers

*Presented at the Mexican School on Nuclear Astrophysics, Guanajuato, Gto., México, Aug 13-20, 1997. A shorten version will be published in “Causality and Locality in Modern Physics. Proceedings of a Symposium in honour of Jean-Pierre Vigier”, eds. G. Hunter, S. Jeffers and J.-P. Vigier, Kluwer Academic, Dordrecht, 1998. The complete version is submitted to “Int. J. Theor. Phys.”
and lectures of S. Weinberg, e.g., [13]: “The kinematical classification of particles according
to their Lorentz transformation properties is entirely (for finite mass) determined by their
familiar representation of the rotation group. It has nothing whatever to do with the choice
of one relativistic wave equation rather than another.” See also [14, 15]. In our opinion, it
is still required to take into account the issues related to the inversion group, namely, the
theoretical possibility of unconventional representations of inversions.

II. CHIRAL INTERACTIONS

We start from the observation that the Dirac field operator, which satisfies the Dirac
equation

\[ [i\gamma^\mu \partial_\mu - m] \psi(x^\mu) = 0 , \]  

(1)
can be expanded in the following parts:

\[ \psi(x^\mu) = \psi_\uparrow(x^\mu) + \psi_\downarrow(x^\mu) , \]  

(2a)
\[ \psi_\uparrow(x^\mu) = \int \frac{d^3p}{(2\pi)^3 2E_p} \left[ u_\uparrow(p^\mu)a_\uparrow(p^\mu)e^{-i\phi} + C u_\uparrow^*(p^\mu)b_\uparrow^\dagger(p^\mu)e^{+i\phi} \right] , \]  

(2b)
\[ \psi_\downarrow(x^\mu) = \int \frac{d^3p}{(2\pi)^3 2E_p} \left[ u_\downarrow(p^\mu)a_\downarrow(p^\mu)e^{-i\phi} - C u_\downarrow^*(p^\mu)b_\downarrow^\dagger(p^\mu)e^{+i\phi} \right] , \]  

(2c)

where \( \phi = (Et - \mathbf{x} \cdot \mathbf{p})/\hbar. \) The charge-conjugate equation is

\[ (i\gamma^\mu \partial_\mu - m) C \psi^\dagger(x^\mu) = 0 ; \]  

(3)

\[ 1 \text{ While this type of theories is usually called as Wigner- (or “BWW-”) type, see [16, 17], the pos-
sibility of unconventional representations of inversions was first indicated by Soviet mathematical}
\text{physicists [18], see also the relevant papers [19].} \]

\[ 2 \text{ As opposed to ref. [3b] we use the conventional notation and metric. Namely, } g^{\mu\nu} = \text{diag}(+1, -1, -1, -1) \text{ and } \gamma \text{ matrices are} \]

\[ \gamma^0 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \gamma^i = \begin{pmatrix} 0 & -\sigma^i \\ \sigma^i & 0 \end{pmatrix}, \quad \gamma^5 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \]

in the Weyl representation. The Pauli charge-conjugation \( 4 \times 4 \) matrix is then

\[ C = e^{i\theta_c} C = e^{i\theta_c} \begin{pmatrix} 0 & \Theta \\ -\Theta & 0 \end{pmatrix} , \text{ where } \Theta = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}. \]

It has the properties

\[ C = C^T , \ C^* = C^{-1} , \]
\[ C^{-1}\gamma^\mu C = -\gamma^\mu , \ C^{-1}\gamma^5 C = -\gamma^5. \]
and the counterparts of the ‘field operators’ (21,24) are (\( \vartheta_c = 0 \))

\[
\psi^c(x^\mu) = \psi^c_\uparrow(x^\mu) + \psi^c_\downarrow(x^\mu),
\]

(4a)

\[
\psi^c_\uparrow(x^\mu) = \int \frac{d^3p}{(2\pi)^3 2E_p} \left[ u^c_\uparrow(p^\mu) b_\downarrow(p^\mu) e^{-i\phi} + Cu^c_\uparrow(p^\mu) a^\dagger_\downarrow(p^\mu) e^{+i\phi} \right],
\]

(4b)

\[
\psi^c_\downarrow(x^\mu) = \int \frac{d^3p}{(2\pi)^3 2E_p} \left[ -u^c_\downarrow(p^\mu) b_\uparrow(p^\mu) e^{-i\phi} + Cu^c_\downarrow(p^\mu) a^\dagger_\uparrow(p^\mu) e^{+i\phi} \right].
\]

(4c)

Both \( \psi_\uparrow \), \( \psi^c_\uparrow \) and \( \psi_\downarrow \), \( \psi^c_\downarrow \) can be used to form self/anti-self charge conjugate field operators in the coordinate representation after regarding corresponding superpositions. For instance,

\[
\Psi^S = \frac{\psi_\uparrow + \psi^c_\downarrow}{2} = \int \frac{d^3p}{(2\pi)^3 2E_p} \left[ u_\uparrow(p^\mu) a^\dagger_\uparrow + b^\dagger_\downarrow + \frac{C}{2} u^c_\uparrow(p^\mu) a^\dagger_\downarrow + b^\dagger_\downarrow e^{+i\phi} \right],
\]

(5a)

\[
\Psi^A = \frac{\psi_\downarrow - \psi^c_\uparrow}{2} = \int \frac{d^3p}{(2\pi)^3 2E_p} \left[ u_\downarrow(p^\mu) a^\dagger_\uparrow + b^\dagger_\downarrow e^{-i\phi} - \frac{C}{2} u^c_\downarrow(p^\mu) a^\dagger_\downarrow + b^\dagger_\downarrow e^{+i\phi} \right],
\]

(5b)

\[
\bar{\Psi}^S = \frac{\psi_\uparrow + \psi^c_\downarrow}{2} = \int \frac{d^3p}{(2\pi)^3 2E_p} \left[ u^\dagger_\uparrow(p^\mu) a_\uparrow + b_\downarrow e^{-i\phi} + \frac{C}{2} u^c_\uparrow(p^\mu) a^\dagger_\downarrow + b^\dagger_\downarrow e^{+i\phi} \right],
\]

(5c)

\[
\bar{\Psi}^A = \frac{\psi_\downarrow - \psi^c_\uparrow}{2} = \int \frac{d^3p}{(2\pi)^3 2E_p} \left[ u^\dagger_\downarrow(p^\mu) a_\uparrow + b_\downarrow e^{-i\phi} - \frac{C}{2} u^c_\downarrow(p^\mu) a^\dagger_\downarrow + b^\dagger_\downarrow e^{+i\phi} \right].
\]

(5d)

As opposed to K. M. Case [3b] we introduce the interaction with the 4-vector potential in the beginning and substitute \( \partial_\mu \rightarrow \nabla_\mu = \partial_\mu - ieA_\mu \) in the equation (1). For the sake of generality we assume that the 4-vector potential is a complex field \( A_\mu = C_\mu + i B_\mu \), what is the extension of this concept comparing with the usual quantum-field consideration [23]. Following the logics of refs. [3,4] (the separation of different chirality sub-spaces) we should consider additional equations for \( \gamma^5 \psi_\uparrow \) and \( \gamma^5 \psi^c_\uparrow \), i.e., the following set

\[
[i \gamma^\mu(\partial_\mu - ieC_\mu + eB_\mu) - m] (\psi_\uparrow + \psi_\downarrow) = 0,
\]

(6a)

\[
[i \gamma^\mu(\partial_\mu + ieC_\mu + eB_\mu) - m] (\psi^c_\uparrow + \psi^c_\downarrow) = 0,
\]

(6b)

\[
[i \gamma^\mu(\partial_\mu - ieC_\mu + eB_\mu) + m] \gamma^5 (\psi_\uparrow + \psi_\downarrow) = 0,
\]

(6c)

\[
[i \gamma^\mu(\partial_\mu + ieC_\mu + eB_\mu) + m] \gamma^5 (\psi^c_\uparrow + \psi^c_\downarrow) = 0.
\]

(6d)

Due to symmetries of the Dirac equations one can proceed in various ways. For instance, let us introduce the following linear combinations

\[
\psi_1 = \psi_\uparrow - \gamma^5 \psi^c_\uparrow, \quad \psi_2 = \psi_\downarrow + \gamma^5 \psi_\uparrow^c, \quad (7a)
\]

\[
\psi_3 = \psi_\uparrow + \gamma^5 \psi_\uparrow, \quad \psi_4 = \psi_\downarrow - \gamma^5 \psi_\downarrow^c. \quad (7b)
\]

\footnote{In the modern textbooks on the classical/quantum field theory the 4-vector potential in the coordinate representation is usually the real function(al). We still note that different choices of a) relations between the left- and right- parts of the momentum-space bispinors; b) relations between creation and annihilation operators in the field operator; and c) metrics would induce ones to change this conclusion for interactions of various field configurations which one considers.}
which can be used to represent solutions of Eqs. (6a-6d). Then we proceed with simple algebraic transformations of the set (6a-6d) to obtain \((\nabla_\mu \equiv \partial_\mu + e B_\mu)
\)

\[
i \gamma^\mu \nabla_\mu (\psi_1 - \gamma^5 \psi_4) - e \gamma^\mu C_\mu (\gamma^5 \psi_2 + \psi_3) - m (\gamma^5 \psi_2 + \psi_3) = 0 ,
\]

\[
i \gamma^\mu \nabla_\mu (\gamma^5 \psi_2 + \psi_3) - e \gamma^\mu C_\mu (\psi_1 - \gamma^5 \psi_4) - m (\psi_1 - \gamma^5 \psi_4) = 0 .
\]

Other two equations are obtained after multiplying (8a,8b) by the \(\gamma^5\) matrix. For the first sight one could conclude that we would obtain different physical excitations (due to mathematically different dynamical equations with different interactions) depending on constraints which we impose on functions \(\psi_{1,2,3,4}\). Let us impose \(\bar{\Psi}^S = 0\) and \(\bar{\Psi}^A = 0\), see Eqs. (5c,5d). They are considered here to be equivalent to either the constraints on the creation/annihilation operators \(a_\uparrow(p^\mu) = b_\downarrow(p^\mu)\) and \(a_\downarrow(p^\mu) = b_\uparrow(p^\mu)\) or the constraints \(\psi_\uparrow = \psi^c_1 \equiv \psi^a\) and \(\psi_\downarrow = -\psi^c_2 \equiv \psi^a\). The functions \(\psi_{1,2,3,4}\) become to be interrelated by the conditions

\[
\psi_1 = \psi^a - \gamma^5 \psi^0 , \quad \psi_2 = \psi^a + \gamma^5 \psi^0 , \quad \psi_3 \equiv \gamma^5 \psi_1 , \quad \psi_4 \equiv \gamma^5 \psi_2 .
\]

It is the simple procedure to show that \(\psi_1\) presents itself self-charge conjugate field and \(\psi_2\), the anti-self charge conjugate field.\(^4\) As the result one obtains

\[
i \gamma^\mu D^\mu_\mu \psi_1 - m \gamma^5 \psi_2 = 0 ,
\]

\[
i \gamma^\mu D^\mu_\mu \psi_2 - m \gamma^5 \psi_1 = 0 ,
\]

where the lengthening derivative is now defined

\[
D^\mu_\mu = \partial_\mu - i e \gamma^5 C_\mu + e B_\mu .
\]

Equations for the Dirac conjugated counterparts of \(\psi_{1,2}\) read

\[
i \partial_\mu \overline{\psi}_1 \gamma^\mu - m \overline{\psi}_2 \gamma^5 = 0 ,
\]

\[
i \partial_\mu \overline{\psi}_2 \gamma^\mu + m \overline{\psi}_1 \gamma^5 = 0 .
\]

One can propose the Lagrangian for free fields \(\psi_{1,2}\) and their Dirac conjugates (cf. with the concept of the extra Dirac equations in ref. [9d] and with the spin-1 case, ref. [20]).\(^6\)

\(^4\)Of course, this is true only if one works with IR representations of the Wigner-Jordan (anti)commutation rules.

\(^5\)As opposed to the above, one can wish to put the constraints \(\Psi^S = \Psi^A = 0\) (or even more general ones), which are considered to be equivalent to \(a_\uparrow = -b_\downarrow\) and \(a_\downarrow = -b_\uparrow\). Thus, one can reformulate the formulas in the rest of the paper. In my opinion, the physical content, which is relevant to the aims of the present article, will not be changed. So, the constraints are used here only for the purposes of simplicity and clarity.

\(^6\)The operator of the charge conjugation and the chirality \(\gamma^5\) operator (chosen as above) are the anti-commuting operators.

\(^7\)At this point we still leave the room for other kinds of the Lagrangians describing self/anti-self charge conjugate states, see below and cf. [7].
\[ L^\text{free} = \frac{i}{2} \left[ \bar{\psi}_1 \gamma^\mu \partial_\mu \psi_1 - \partial_\mu \bar{\psi}_1 \gamma^\mu \psi_1 + \bar{\psi}_2 \gamma^\mu \partial_\mu \psi_2 - \partial_\mu \bar{\psi}_2 \gamma^\mu \psi_2 \right] + 
\]
\[ - m \left[ \bar{\psi}_1 \gamma^5 \psi_2 - \bar{\psi}_2 \gamma^5 \psi_1 \right]; \quad (12) \]

and the terms of the interaction:
\[ L^\text{int} = -e(\bar{\psi}_1 \gamma^\mu \gamma^5 \psi_1 - \bar{\psi}_2 \gamma^\mu \gamma^5 \psi_2)C_\mu + ie(\bar{\psi}_1 \gamma^\mu \psi_1 + \bar{\psi}_2 \gamma^\mu \psi_2)B_\mu \quad (13) \]

The conclusion that self/anti-self charge conjugate can possess the axial charge (of opposite values) is in accordance with the conclusions of refs. \[ \text{[6,7]} \] and with the old ideas of R. E. Marshak \[ \text{[21]} \]. It is remarkable feature of this model that we did not assume that self/anti-self charge conjugate fields are massless.

One can come to this conclusion on using another way of speculations. Equations (1,3) with interaction can be presented in two-component form \((\psi = \text{column}(\phi \ \chi))\) and
\[ \sigma^\mu = \left( \begin{pmatrix} 1 & 1 \\ 2 & -2 \end{pmatrix}, -\sigma^i \right) \]
with the hermitian conjugation acting on the \(q\)- numbers (it acts on the \(c\)- numbers as the complex conjugation). Introducing other bispinors
\[ R^{S,A} = \left( \begin{array}{c} \phi \\ \mp \Theta \phi^\dagger \end{array} \right), \quad L^{S,A} = \left( \begin{array}{c} \pm \Theta \chi^\dagger \\ \chi \end{array} \right), \quad (15) \]
and combining the second and the third equation, and then, the first and the fourth equations, one can arrive at the equations for new bispinors:
\[ i\gamma^\mu D_\mu R^{S,A} - m L^{S,A} = 0, \quad (16a) \]
\[ i\gamma^\mu D^*_\mu L^{S,A} - m R^{S,A} = 0. \quad (16b) \]

After taking into account relations between \(R^S\) and \(R^A\) (and between \(L^S\) and \(L^A\)) we can obtain two sets:
\[ i\gamma^\mu D_\mu \mathcal{L}^S - m \mathcal{R}^A = 0, \quad i\gamma^\mu D_\mu \mathcal{R}^S + m \gamma^5 \mathcal{L}^A = 0; \quad (17) \]
and/or
\[ i\gamma^\mu D_\mu \mathcal{R}^S + m \gamma^5 \mathcal{L}^A = 0, \quad i\gamma^\mu D_\mu \mathcal{L}^S - m \gamma^5 \mathcal{R}^A = 0. \quad (18) \]

They are precisely the equations which we obtained before (cf. (10a,10b) and the equations multiplied by the \(\gamma^5\) matrix). If we now impose the Majorana anzatz \(8\phi = e^{i\alpha} \Theta \chi^\dagger\) on all four

8\(\alpha\) is an arbitrary phase factor. It is easy to note that in the case of \(\alpha = 0\) the Majorana anzatz results in \(R^S = +\mathcal{L}^S\) and \(R^A = -\mathcal{L}^A\). But, in the case \(\alpha = \pi\) one obtains \(R^S = -\mathcal{L}^S\) and \(R^A = +\mathcal{L}^A\).
equations we obtain that the $\gamma^5$ interaction terms seem to disappear. Due to our previous research [5–7], which was based on other postulates (see also below), we are sure in the necessity of modifications of the Dirac theory for neutral particles and in the presence of the $\gamma^5$ interactions. In fact, Majorana ansatz (e. g., with $\alpha = 0$) is connected with the interrelations between field operators $\psi_{1,2}$ above. So, we may loose some information. How to solve the problem rigorously? See below.

Further arguments in aid of our reasoning are given by several constructs which appeared recently [6,5,9,7]. The Ahluwalia reformulation of the McLennan-Case construct was presented in 1994 [5]. The following type-II spinors have been defined in the momentum space:

$$\lambda^{S,A}(p^\mu) = \left( \zeta_\lambda \Theta_{[\lambda]} \phi_{L}(p^\mu) \right), \quad \rho^{S,A}(p^\mu) = \left( \zeta_\rho \Theta_{[\rho]} \phi_{R}^*(p^\mu) \right). \quad (19)$$

In our choice of the operator of the charge conjugation ($\vartheta_c = 0$) the phase factors $\zeta_\lambda, \zeta_\rho$ are defined as $\pm 1$, for $\lambda^S(\rho^S)$, and $\mp 1$, for $\lambda^A(\rho^A)$, respectively. One can find relations between the type-II spinors and the Dirac spinors. They are listed here

$$\lambda^S_{\uparrow}(p^\mu) = +\rho^S_{\uparrow}(p^\mu) = + \frac{1 - \gamma^5}{2} u_{\uparrow}(p^\mu) + \frac{1 + \gamma^5}{2} u_{\downarrow}(p^\mu), \quad (20a)$$
$$\lambda^S_{\downarrow}(p^\mu) = -\rho^S_{\uparrow}(p^\mu) = - \frac{1 + \gamma^5}{2} u_{\uparrow}(p^\mu) + \frac{1 - \gamma^5}{2} u_{\downarrow}(p^\mu), \quad (20b)$$
$$\lambda^A_{\uparrow}(p^\mu) = -\rho^A_{\uparrow}(p^\mu) = - \frac{1 - \gamma^5}{2} u_{\uparrow}(p^\mu) + \frac{1 + \gamma^5}{2} u_{\downarrow}(p^\mu), \quad (20c)$$
$$\lambda^A_{\downarrow}(p^\mu) = +\rho^A_{\uparrow}(p^\mu) = + \frac{1 + \gamma^5}{2} u_{\uparrow}(p^\mu) + \frac{1 - \gamma^5}{2} u_{\downarrow}(p^\mu). \quad (20d)$$

The positive-energy solutions are assumed in ref. [5] to be presented by, e. g., self charge conjugate $\lambda^S$ spinors, the negative-energy solutions, by anti-self charge conjugate $\lambda^A$ spinors:

$$\nu(x^\mu) = \lambda^S(x^\mu) + \lambda^A(x^\mu) \equiv \int \frac{d^3p}{(2\pi)^3} \frac{1}{2p_0} \sum_\eta \left[ \lambda^S_\eta(p^\mu) c_\eta(p^\mu) \exp(-ip \cdot x) + \lambda^A_\eta(p^\mu) d_\eta^*(p^\mu) \exp(+ip \cdot x) \right]. \quad (21)$$

Of course, one can construct the field operator composed of $\rho^{S,A}$ bispinors, e. g.,

---

9Let me remind that the sign of the phase in the field operator is considered to be invariant if we restrict ourselves by the orthochronous proper Poincaré group. This fact has been used at the stage of writing the dynamical equations (23a,23b,24b,24b), see below.

10Field operators in this construct may be not self/anti-self charge conjugate operator. So, the notation ($S, A$) used in the formulas in the coordinate space indicates only the presence of self/anti-self charge conjugate states and does not refer to the properties of the field operator.
\[ \tilde{\nu}(x^\mu) = \rho^A(x^\mu) + \rho^S(x^\mu) \equiv \int \frac{d^3 p}{(2\pi)^3} \frac{1}{2p_0} \sum_\eta \left[ \rho^A_\eta(p^\mu)e_\eta(p^\mu) \exp(-ip \cdot x) + \rho^S_\eta(p^\mu)f_\eta^\dagger(p^\mu) \exp(+ip \cdot x) \right]. \] (22)

One of surprising features of this construct \[5,7\] is the fact that dynamical equations take eight-component form from the beginning. As shown there the equations for self/anti-self charge conjugate states read:

\[ i\gamma^\mu \partial_\mu \lambda^S(x^\mu) + m\rho^A(x^\mu) = 0 \quad , \]
\[ i\gamma^\mu \partial_\mu \rho^A(x^\mu) + m\lambda^S(x^\mu) = 0 \quad ; \] (23a)
(23b)

and

\[ i\gamma^\mu \partial_\mu \lambda^A(x^\mu) - m\rho^S(x^\mu) = 0 \quad , \]
\[ i\gamma^\mu \partial_\mu \rho^S(x^\mu) - m\lambda^A(x^\mu) = 0 \quad . \] (24a)
(24b)

They can be written in the 8-component form as follows (see formulas (21) in \[7\] for \(\Gamma\) matrices):

\[ [i\Gamma^\mu \partial_\mu + m] \Psi_+(x^\mu) = 0 \quad , \]
\[ [i\Gamma^\mu \partial_\mu - m] \Psi_-(x^\mu) = 0 \quad , \] (25a)
(25b)

where

\[ \Psi_+(x^\mu) = \begin{pmatrix} \rho^A(x^\mu) \\ \lambda^S(x^\mu) \end{pmatrix} \quad , \quad \Psi_-(x^\mu) = \begin{pmatrix} \rho^S(x^\mu) \\ \lambda^A(x^\mu) \end{pmatrix} \quad . \] (26)

One can reveal the possibility of the \(\gamma^5\) phase transformations \[7\]. The Lagrangian \[7, Eq.(24)\], which (like in the Dirac construct) becomes to be equal to zero on the solutions of the dynamical equations:

\[ \mathcal{L} = \frac{i}{2} \left[ \lambda^S \gamma^\mu \partial_\mu \lambda^S - (\partial_\mu \lambda^S)\gamma^\mu \lambda^S + \rho^A \gamma^\mu \partial_\mu \rho^A - (\partial_\mu \rho^A)\gamma^\mu \rho^A + \lambda^S \gamma^\mu \partial_\mu \lambda^A - (\partial_\mu \lambda^A)\gamma^\mu \lambda^A + \rho^S \gamma^\mu \partial_\mu \rho^S - (\partial_\mu \rho^S)\gamma^\mu \rho^S \right] + m \left[ \lambda^S \rho^A + \rho^A \lambda^S - \lambda^A \rho^S - \rho^S \lambda^A \right] \] (27)

is invariant with respect to the phase transformations:

\[ \lambda'(x^\mu) \rightarrow \cos \alpha - i\gamma^5 \sin \alpha \lambda(x^\mu) \quad , \]
\[ \lambda'(x^\mu) \rightarrow \lambda(x^\mu)(\cos \alpha - i\gamma^5 \sin \alpha) \quad , \] (28a)
(28b)
\[ \rho'(x^\mu) \rightarrow \cos \alpha + i\gamma^5 \sin \alpha \rho(x^\mu) \quad , \]
\[ \rho'(x^\mu) \rightarrow \rho(x^\mu)(\cos \alpha + i\gamma^5 \sin \alpha) \quad . \] (28c)
(28d)

---

\(^{11}\)\(\partial_c = 0\) again. The sign in the mass term depends on this phase factor.

\(^{12}\)The overline implies the Dirac conjugation.
Obviously, the 4-spinors $\lambda^{S,A}(p^\mu)$ and $\rho^{S,A}(p^\mu)$ remain in the space of self/anti-self charge conjugate states. In terms of the field functions $\Psi(\pm)(x^\mu)$ the transformation formulas recast as follows ($L^5 = \text{diag}(\gamma^5, -\gamma^5)$ and $\Psi(\pm) \equiv \Psi(\pm)\Gamma^0$)

$$\Psi'(\pm)(x^\mu) \to \left(\cos \alpha + iL^5 \sin \alpha\right)\Psi(\pm)(x^\mu),$$

$$\Psi'(\pm)(x^\mu) \to \overline{\Psi(\pm)}(x^\mu)\left(\cos \alpha - iL^5 \sin \alpha\right).$$

Let us proceed further with the local gradient transformations (gauge transformations) in the Majorana-Ahluwalia construct. When we are interested in them one must introduce the compensating field of the 4-vector potential

$$\partial_\mu \to \nabla_\mu = \partial_\mu + i\epsilon L^5 A_\mu,$$

$$A'_\mu(x) \to A_\mu(x) - \frac{1}{\epsilon} \partial_\mu \alpha.$$}

Therefore, equations describing interactions of the $\lambda^S$ and $\rho^A$ with 4-vector potential are the following

$$i\gamma^\mu \partial_\mu \lambda^S(x^\mu) + e\gamma^\mu \gamma^5 A_\mu \lambda^S(x^\mu) + m\rho^A(x^\mu) = 0,$$

$$i\gamma^\mu \partial_\mu \rho^A(x^\mu) - e\gamma^\mu \gamma^5 A_\mu \rho^A(x^\mu) + m\lambda^S(x^\mu) = 0.$$}

The second-order equations follow immediately form the set $$\left\{\begin{array}{ll}
\Pi_+^+ \Pi^\mu + m^2 + e\gamma^5 \Sigma^{\mu\nu} F_{\nu\mu} & \lambda^{S,A}(x^\mu) = 0, \\
\Pi_-^+ \Pi^\mu - m^2 - e\gamma^5 \Sigma^{\mu\nu} F_{\nu\mu} & \rho^{A,S}(x^\mu) = 0,
\end{array}\right.$$}

with the notation being used: $\hat{A} \equiv \gamma^\mu A_\mu = \gamma^0 A^0 - (\gamma \cdot A)$. After algebraic transformations in a spirit of one obtains

$$\Pi^\pm \equiv \frac{1}{\epsilon} \partial_\mu \pm e\gamma^5 A_\mu,$$}

13Usual phase transformations like that applied to the Dirac field will destroy self/anti-self charge conjugacy. The origin lies in the fact that the charge conjugation operator is not a linear operator and it includes the operation of complex conjugation.

14The case of $\lambda^A$ and $\rho^S$ is similar.
and

\[ \Sigma^\mu\nu = \frac{i}{2} [\gamma^\mu, \gamma^\nu]_-. \]  

(35)

Thus, we see that the second-order equations for the particles described by the field operator \( \nu(x^\mu) \) (Eq. (46) in [5] and Eq. (21) of this paper), which interact with the 4-vector potential, have the same form for positive- and negative-energy parts. The same is true in the case of the use of the field operator composed from \( \rho^A \) and \( \rho^S \). One can see the difference with the Dirac case; namely, the presence of \( \gamma^5 \) matrix in the “Pauli term” and in the lengthening derivatives. Next, we are able to decouple the set (33a,33b) for the up- and down- components of the bispinors in the coordinate representation. For instance, the up- and the down- parts of the \( \nu^{DL}(x) = \text{column}(\xi \eta) \) interact with the vector potential in the following manner:

\[
\begin{cases}
\left[ \pi_\mu^+ \pi^\mu + m^2 + \frac{ie}{2} \sigma^{\mu\nu} F_{\mu\nu} \right] \xi(x^\mu) = 0 , \\
\left[ \pi_\mu^- \pi^\mu - m^2 - \frac{ie}{2} \sigma^{\mu\nu} F_{\mu\nu} \right] \eta(x^\mu) = 0 ,
\end{cases}
\]  

(36)

where already one has \( \pi^\pm_\mu = i \partial_\mu \pm e A_\mu \), \( \sigma^{0i} = -\overline{\sigma}^{0i} = i\sigma^i \), \( \sigma^{ij} = \overline{\sigma}^{ij} = \epsilon_{ijk} \sigma^k \). Of course, introducing the operator composed of the \( \rho \) states one can write corresponding equations for its up- and down- components and, hence, restore the Feynman-Gell-Mann equation [24, Eq.(3)] and its charge conjugate (if one considers that \( A^\mu \) and \( F^{\mu\nu} \) are the real fields). In fact, this way would lead us to the consideration which is identical to the recent papers [25]. It was based on the linearization procedure for 2-spinors, which is similar to that used by Feshbach and Villars [26] in order to deduce the Hamiltonian form of the Klein-Gordon equation. Some insights in the interaction issues with the 4-vector potential in the eight-component equation have been made there: for instance, while explicit form of the wave functions slightly differ from the Dirac case, the hydrogen atom spectrum is the same to that in the usual Dirac theory [23, p.66,74-75]. Next, like in the paper [27] the equations of [25] presume a non-CP-violating electric dipole moment of the corresponding states.

Next, by using the relations (20a-20d) one can deduce how is the \( \nu \) operator, which was given by D. V. Ahluwalia, connected with the Dirac field operator and its charge conjugate. In the particular case when \((a_\uparrow + b_\downarrow)/2 = (a_\downarrow - b_\uparrow)/2 \equiv c_\uparrow = d_\downarrow \) and \((a_\uparrow + b_\downarrow)/2 = (a_\downarrow - b_\uparrow)/2 \equiv c_\downarrow = d_\uparrow \) one has

15 One can connect the Feynman-Gell-Mann field with \( \nu(x^\mu) \) and \( \tilde{\nu}(x^\mu) \) defined in (21,22). For instance,

\[
\Psi^{FGM} = \frac{1 + \gamma^5}{2} \tilde{\nu} \pm \frac{1 - \gamma^5}{2} \nu ,
\]  

(37a)

\[
(\Psi^{FGM})^c = \frac{1 + \gamma^5}{2} \nu \pm \frac{1 - \gamma^5}{2} \tilde{\nu} .
\]  

(37b)

But the signs are not fixed in the framework of this consideration (due to the fact that the Feynman-Gell-Mann equations are of the second order and the left-hand side operator (see Eq. (3) in [24]) commutes with the \( \gamma^5 \) matrix.

16 This is possible due to the Wigner “doubling” of the components of the wave function.
The operator composed of $\rho$ spinors is then expressed

$$\nu(x^\mu) = \frac{1}{2}(\psi(x^\mu) - \psi^c(x^\mu)) - \frac{\gamma^\mu}{2}(\psi(x^\mu) + \psi^c(x^\mu)).$$ (38)

Other fields which we use in order to obtain dynamical equations are

$$\nu^c(x^\mu) = \frac{1}{2}(\psi(x^\mu) + \psi^c(x^\mu)) + \frac{\gamma^\mu}{2}(\psi(x^\mu) - \psi^c(x^\mu)).$$ (39)

After rather tiresome calculational procedure one obtains the dynamical equations in this approach

$$i\gamma^\mu \nabla_\mu (\nu - \nu^c) - e\gamma^\mu \gamma^5 C_\mu (\nu - \nu^c) - m\gamma^5 (\bar{\nu} + \bar{\nu}^c) = 0,$$ (40a)

$$\gamma^5 \nu(x^\mu) = -\frac{1}{2}(\psi(x^\mu) - \psi^c(x^\mu)) + \frac{\gamma^\mu}{2}(\psi(x^\mu) + \psi^c(x^\mu)),$$ (40b)

$$\gamma^5 \nu^c(x^\mu) = -\frac{1}{2}(\psi(x^\mu) + \psi^c(x^\mu)) + \frac{\gamma^\mu}{2}(\psi(x^\mu) - \psi^c(x^\mu)),$$ (40c)

$$\gamma^5 \bar{\nu}(x^\mu) = -\frac{1}{2}(\psi(x^\mu) - \psi^c(x^\mu)) + \frac{\gamma^\mu}{2}(\psi(x^\mu) + \psi^c(x^\mu)),$$ (40d)

$$\gamma^5 \bar{\nu}^c(x^\mu) = -\frac{1}{2}(\psi(x^\mu) + \psi^c(x^\mu)) + \frac{\gamma^\mu}{2}(\psi(x^\mu) - \psi^c(x^\mu)).$$ (40f)

or

$$(1 + \gamma^5) [i\gamma^\mu \nabla_\mu (\nu - \nu^c) + \bar{\nu}(x^\mu) + \bar{\nu}^c(x^\mu) + e\gamma^\mu C_\mu (\nu - \nu^c) - m(\bar{\nu} + \bar{\nu}^c)] = 0,$$ (41a)

$$(1 + \gamma^5) [i\gamma^\mu \nabla_\mu (\nu - \nu^c) + e\gamma^\mu C_\mu (\nu - \nu^c) + m(\bar{\nu} + \bar{\nu}^c)] = 0,$$ (42a)

$$(1 - \gamma^5) [i\gamma^\mu \nabla_\mu (\nu - \nu^c) + e\gamma^\mu C_\mu (\nu - \nu^c) + m(\bar{\nu} + \bar{\nu}^c)] = 0,$$ (42b)

$$(1 - \gamma^5) [i\gamma^\mu \nabla_\mu (\nu - \nu^c) + e\gamma^\mu C_\mu (\nu - \nu^c) + m(\bar{\nu} + \bar{\nu}^c)] = 0,$$ (42c)

Thus, one can see the operators

$$\nu(x^\mu) - \nu^c(x^\mu), \text{ and } (\bar{\nu}(x^\mu) + \bar{\nu}^c(x^\mu)),$$

also satisfy the equations of the type $[10a,11t]$. From the formulas $[18,19]$ one can figure out, why do Eqs. $[17,18]$ and $[23a,24l]$ have different forms and how are $R^{S,A}, L^{S,A}$, the self/anti-self charge conjugate operators, and $\lambda^{S,A}, \rho^{S,A}$, the operators answering for the self/anti-self charge conjugate states, connected?

\[17\] Of course, certain relations between creation/annihilation operators of various field operators are again assumed.
III. THE TERM $\sigma \cdot [A \times A^*]$: TO BE OR NOT TO BE?

The possibility of terms as $\sim \sigma \cdot [A \times A^*]$, ref. [28,29], appears to be related to the matters of chiral interactions. As we are now convinced, the Dirac field operator can be always presented as a superposition of the self- and anti-self charge conjugate ‘field operators’. The anti-self charge conjugate part can give the self charge conjugate part after multiplying by the $\gamma^5$ matrix and vice versa. In the equations (9) we are able to put further constraints to extract the self-conjugate states. For instance,

$$\gamma^5 \psi_2 = \psi_1 \quad (43)$$

or, the anti-self charge conjugate states:

$$\gamma^5 \psi_1 = -\psi_2 \quad (44)$$

Hence, one has

$$[i\gamma^\mu D^*_\mu - m]\psi^*_1 = 0 \quad (46)$$

or

$$[i\gamma^\mu D_\mu - m]\psi_2 = 0 \quad (48)$$

Both equations lead to the terms of interaction such as $\sim \sigma \cdot [A \times A^*]$ provided that the 4-vector potential is considered as a complex function(al). In fact, from (46) we have:

$$i\sigma^\mu \nabla_\mu \chi_1 - m\phi_1 = 0 \quad (49a)$$

$$i\tilde{\sigma}^\mu \nabla^*_\mu \phi_1 - m\chi_1 = 0 \quad (49b)$$

And, from (48) we have

$$i\sigma^\mu \nabla^*_\mu \chi_2 - m\phi_2 = 0 \quad (50a)$$

$$i\tilde{\sigma}^\mu \nabla_\mu \phi_2 - m\chi_2 = 0 \quad (50b)$$

18 The anti-self charge conjugate field function $\psi_2$ can also be used. The equation has then the form:

$$[i\gamma^\mu D^*_\mu + m]\psi^*_2 = 0 \quad (45).$$

19 The self charge conjugate field function $\psi_1$ also can be used. The equation has the form:

$$[i\gamma^\mu D_\mu + m]\psi^*_1 = 0 \quad (47)$$

As readily seen in the cases of alternative choices we have opposite “charges” in the terms of the type $\sim \sigma \cdot [A \times A^*]$ and in the mass terms.
The meanings of $\sigma^\mu$ and $\bar{\sigma}^\mu$ are obvious from the definition of $\gamma$ matrices. From the above set we extract the terms as $\pm e^2 \sigma^i_{Pauli} \bar{\sigma}^j_{Pauli} A_i A_j^*$, which lead to the discussed terms [28,29].

Furthermore, one can come to the same conclusions not applying to the constraints on the creation/annihilation operators (which we chosen previously for clarity and simplicity). It is possible to work with self/anti-self charge conjugate momentum-space objects in the (1,0) representation. One can see the problems of introducing analogue s self/anti-self charge conjugate states. But, as we discussed in [9c] (see also [5]) it is impossible to (0) the submitted Esposito-Recami paper the terms of the type Recami-Evans term with those which have been used in [29]. We would like to note that in field configurations (helicity, self/anti-self charge conjugate properties etc) in the coordinate representation.

Thus, in the considered cases it is the $\gamma^5$ transformation which distinguishes various field configurations (helicity, self/anti-self charge conjugate properties etc) in the coordinate representation.

It would be interesting to compare the above arguments for derivation of the Esposito-Recami-Evans term with those which have been used in [29]. We would like to note that in the submitted Esposito-Recami paper the terms of the type $\sim \sigma \cdot [A \times A^*]$ can be reduced to $(\sigma \cdot \nabla)\mathcal{V}$, where $\mathcal{V}$ is the scalar potential.

**IV. GENERALIZATIONS TO HIGHER SPIN REPRESENTATIONS AND CONCLUSIONS**

As we have learnt the $\gamma^5$ interactions is intimately related to the question of defining the self/anti-self charge conjugate states. But, as we discussed in [9c] (see also [5]) it is impossible to introduce self/anti-self charge conjugate momentum-space objects in the $(1,0) \oplus (0,1)$ representation. One can see the problems of introducing analogues of $\psi_{1,2,3,4}$ in the $(1,0) \oplus (0,1)$ representation, for instance, from these formulas:

$$
\psi_+^{(x^\mu)} = \int \frac{d^3p}{(2\pi)^32E_p} [u_+(p^\mu)a_+(p^\mu)e^{-i\phi} + Cu_+^*(p^\mu)b_+^\dagger(p^\mu)e^{+i\phi}] ,
$$

$$
\psi_-^{(x^\mu)} = \int \frac{d^3p}{(2\pi)^32E_p} [u_-(p^\mu)a_-(p^\mu)e^{-i\phi} + Cu_-^*(p^\mu)b_-^\dagger(p^\mu)e^{+i\phi}] ,
$$

$$
\psi_0^{(x^\mu)} = \int \frac{d^3p}{(2\pi)^32E_p} [u_0(p^\mu)a_0(p^\mu)e^{-i\phi} - Cu_0^*(p^\mu)b_0^\dagger(p^\mu)e^{+i\phi}] ,
$$

and

$$
\psi_0^c^{(x^\mu)} = \int \frac{d^3p}{(2\pi)^32E_p} [-u_0(p^\mu)b_0(p^\mu)e^{-i\phi} + Cu_0^*(p^\mu)a_0^\dagger(p^\mu)e^{+i\phi}] ,
$$

$$
\psi_-^{(x^\mu)} = \int \frac{d^3p}{(2\pi)^32E_p} [-u_-(p^\mu)b_-(p^\mu)e^{-i\phi} + Cu_-^*(p^\mu)a_-^\dagger(p^\mu)e^{+i\phi}] ,
$$

$$
\psi_0^{(x^\mu)} = \int \frac{d^3p}{(2\pi)^32E_p} [u_0(p^\mu)b_0(p^\mu)e^{-i\phi} + Cu_0^*(p^\mu)a_0^\dagger(p^\mu)e^{+i\phi}] ,
$$

The equation $S^c \psi(x^\mu) = e^{i\alpha} \psi(x^\mu)$ with

$$
S^c = CK = e^{i\varphi_1} \begin{pmatrix}
0 & \Theta_{[1]}^T \\
-\Theta_{[1]} & 0
\end{pmatrix} K , \quad \Theta_{[1]} = \begin{pmatrix}
0 & 0 & 1 \\
0 & -1 & 0 \\
1 & 0 & 0
\end{pmatrix}
$$

(53)
defined in ref. [17,5], has no solutions in the field of complex numbers. We use the following analogues of the formulas of the footnote 2 for the Barut-Muzinich-Williams matrices

\[ C^T = -C, \quad C^* = C = -C^{-1} \]  
\[ C_{\gamma^{\mu\nu}} C^{-1} - \gamma^{\mu\nu}, \quad C_{\gamma^5} C^{-1} = -\gamma^5. \]  

Furthermore, in the Majorana representation of $\gamma^{\mu\nu}$ matrices the operator of the charge conjugation ($\vartheta_c = 0$) is equal to

\[ S_{[1]}^c = \gamma^5_{MR} K = i\gamma^5_{WR} \gamma^0_{WR} K = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix} K. \]  

Thus, if one implies that $\varphi_{u,v} = i(\partial/\partial t)/E = \pm1$ the Weinberg-Ahluwalia equation of ref. [17] transforms as follows:

\[ [\gamma^{\mu\nu} \partial_{\mu} \partial_{\nu} + \varphi_{u,v} m^2] \psi(x^\mu) = 0 \Rightarrow [\gamma^{\mu\nu} \partial_{\mu} \partial_{\nu} + \varphi_{u,v} m^2] \psi^c(x^\mu) = 0. \]  

Please notice that the operator $\varphi_{u,v} = \pm1$ defined above has the following property with respect to the ordinary complex conjugation $\varphi^*_{u,v} = -\varphi_{u,v},$ cf. [30].

Finally, in the Majorana representation the analogues of (6a-6d) have the form:

\[ [\gamma^{\mu\nu} \nabla_{\mu} \nabla_{\nu} + \varphi_{u,v} m^2] \psi(x^\mu) = 0, \]  
\[ [\gamma^{\mu\nu} \nabla^*_{\mu} \nabla^*_{\nu} + \varphi_{u,v} m^2] \gamma^5 \psi^*(x^\mu) = 0, \]  
\[ [\gamma^{\mu\nu} \nabla_{\mu} \nabla_{\nu} - \varphi_{u,v} m^2] \gamma^5 \psi(x^\mu) = 0, \]  
\[ [\gamma^{\mu\nu} \nabla^*_{\mu} \nabla^*_{\nu} - \varphi_{u,v} m^2] \psi^*(x^\mu) = 0. \]  

It is seen after calculations which are similar to above that the combinations $\psi + \psi^*$ and $\gamma^5(\psi - \psi^*)$ may have interaction of the ‘axial’ form.

Concluding, we state that the $\gamma^5$ interaction is indispensable element of $(1/2,0) \oplus (0,1/2)$ representation space (and, presumably, of all the representations of the type $(j,0) \oplus (0,j)$).

We discussed important physical consequences of the presence of this interaction for the particles of this representation and found relations to other models. The proper account of such terms may lead to deeper understanding of the nature of particle interactions in the modern gauge theories, of the structure of the Fock space and reasons for introduction of the latter as well.

Acknowledgments. I am grateful to Profs. D. V. Ahluwalia, A. E. Chubykalo, S. Esposito, A. F. Pashkov, E. Recami, R. M. Santilli and G. Ziino for discussions and useful information. Zacatecas University, México, is thanked for awarding the professorship. This work has been partly supported by the Mexican Sistema Nacional de Investigadores, the Programa de Apoyo a la Carrera Docente and by the CONACyT, México under the research project 0270P-E.
