CENTRAL LIMIT THEOREM FOR THE ROBUST LOG-REGRESSION WAVELET ESTIMATION OF THE MEMORY PARAMETER IN THE GAUSSIAN SEMI-PARAMETRIC CONTEXT

O. KOUAMO, C. LÉVY-LEDUC, AND E. MOULINES

Abstract. In this paper, we study robust estimators of the memory parameter $d$ of a (possibly) non-stationary Gaussian time series with generalized spectral density $f^*$. This generalized spectral density is characterized by the memory parameter $d$ and by a function $f^*$ which specifies the short-range dependence structure of the process. Our setting is semi-parametric since both $f^*$ and $d$ are unknown and $d$ is the only parameter of interest. The memory parameter $d$ is estimated by regressing the logarithm of the estimated variance of the wavelet coefficients at different scales. The two estimators of $d$ that we consider are based on robust estimators of the variance of the wavelet coefficients, namely the square of the scale estimator proposed by [27] and the median of the square of the wavelet coefficients. We establish a Central Limit Theorem for these robust estimators as well as for the estimator of $d$ based on the classical estimator of the variance proposed by [19]. Some Monte-Carlo experiments are presented to illustrate our claims and compare the performance of the different estimators. The properties of the three estimators are also compared on the Nile River data and the Internet traffic packet counts data. The theoretical results and the empirical evidence strongly suggest using the robust estimators as an alternative to estimate the memory parameter $d$ of Gaussian time series.

1. Introduction

Long-range dependent processes are characterized by hyperbolically slowly decaying correlations or by a spectral density exhibiting a fractional pole at zero frequency. During the last decades, long-range dependence (and the closely related self-similarity phenomena) has been observed in many different fields, including financial econometrics, hydrology or analysis of Internet traffic. In most of these applications, however, the presence of atypical observations is quite common. These outliers might be due to gross errors in the observations but also to unmodeled disturbances; see for example [31] and [30] for possible explanations of the presence of outliers in Internet traffic analysis. It is well-known that even a few atypical observations can severely affect estimators, leading to incorrect conclusions. Hence, defining

Key words and phrases. Memory Parameter Estimator, Scale Estimator, Long Range Dependence, Robustness, Wavelet Analysis, Semi-Parametric estimation.
robust estimators of the memory parameter which are less sensitive to the presence of additive outliers is a challenging practical problem.

In this paper, we consider the class of fractional processes, denoted \( M(d) \) defined as follows. Let \( X = \{X_k\}_{k \in \mathbb{Z}} \) be a real-valued Gaussian process, not necessarily stationary and denote by \( \Delta X \) the first order difference of \( X \), defined by \( [\Delta X]_n = X_n - X_{n-1}, \ n \in \mathbb{Z} \). Define, for an integer \( K \geq 1 \), the \( K \)-th order difference recursively as follows: \( \Delta^K = \Delta \circ \Delta^{K-1} \). Let \( f^* \) be a bounded non-negative symmetric function which is bounded away from zero in a neighborhood of the origin. Following [20], we say that \( X \) is an \( M(d) \) process if for any integer \( K > d - 1/2 \), \( \Delta^K X \) is stationary with spectral density function
\[
\hat{f}_{\Delta^K X}(\lambda) = |1 - e^{-i\lambda}|^{-2(K-d)} f^*(\lambda), \quad \lambda \in (-\pi, \pi).
\]
(1)

Observe that \( \hat{f}_{\Delta^K X}(\lambda) \) in (1) is integrable since \( -(K-d) < 1/2 \). When \( d \geq 1/2 \), the process is not stationary. One can nevertheless associate to \( X \) the function
\[
f(\lambda) = |1 - e^{-i\lambda}|^{-2d} f^*(\lambda),
\]
(2)
which is called a generalized spectral density function. In the sequel, we assume that \( f^* \in \mathcal{H}(\beta,L) \) with \( 0 < \beta \leq 2 \) and \( L > 0 \) where \( \mathcal{H}(\beta,L) \) denotes the set of non-negative and symmetric functions \( g \) satisfying, for all \( \lambda \in (-\pi, \pi) \),
\[
|g(\lambda) - g(0)| \leq L g(0) |\lambda|^\beta.
\]
(3)

Our setting is semi-parametric in that both \( d \) and \( f^* \) in (2) are unknown. Here, \( f^* \) can be seen as a nuisance parameter whereas \( d \) is the parameter of interest. This assumption on \( f^* \) is typical in the semi-parametric estimation setting; see for instance [25] and [21] and the references therein.

Different approaches have been proposed for building robust estimators of the memory parameter for \( M(d) \) processes in the semi-parametric setting outlined above. [31] have proposed a robustified wavelet based-regression estimator developed by [1]; the robustification is achieved by replacing the estimation of the wavelet coefficients variance at different scales by the median of the square of the wavelet coefficients. Another technique to robustify the wavelet regression technique has been outlined in [23] which consists in regressing the logarithm of the square of the wavelet coefficients at different scales. [18] proposed a robustified version of the log-periodogram regression estimator introduced in [14]. The method replaces the log-periodogram of the observation by a robust estimator of the spectral density in the neighborhood of the zero frequency, obtained as the discrete Fourier transform of a robust autocovariance estimator defined in [17]; the procedure is appealing and has been found to work well but also lacks theoretical support in the semi-parametric context (note however
that the consistency and the asymptotic normality of the robust estimator of the covariance have been discussed in [16]).

In the related context of the estimation of the fractal dimension of locally self-similar Gaussian processes [10] has proposed a robust estimator of the Hurst coefficient; instead of using the variance of the generalized discrete variations of the process (which are closely related to the wavelet coefficients, despite the facts that the motivations are quite different), this author proposes to use the empirical quantiles and the trimmed-means. The consistency and asymptotic normality of this estimator is established for a class of locally self-similar processes, using a Bahadur-type representation of the sample quantile; see also [9]. [28] proposes to replace the classical regression of the wavelet coefficients by a robust regression approach, based on Huberized M-estimators.

The two robust estimators of $d$ that we propose consist in regressing the logarithm of robust variance estimators of the wavelet coefficients of the process $X$ on a range of scales. We use as robust variance estimators the square of the scale estimator proposed by [27] and the square of the mean absolute deviation (MAD). These estimators are a robust alternative to the estimator of $d$ proposed by [19] which uses the same method but with the classical variance estimator. Here, we derive a Central Limit Theorem (CLT) for the two robust estimators of $d$ and, by the way, we give another methodology for obtaining a Central Limit Theorem for the estimator of $d$ proposed by [19]. In this paper, we have also established new results on the empirical process of array of stationary Gaussian processes by extending [2, Theorem 4] and the Theorem of [11] to arrays of stationary Gaussian processes. These new results were very helpful in establishing the CLT for the three estimators of $d$ that we propose.

The paper is organized as follows. In Section 2, we introduce the wavelet setting and define the wavelet based regression estimators of $d$. Section 3 is dedicated to the asymptotic properties of the robust estimators of $d$. In this section, we derive asymptotic expansions of the wavelet spectrum estimators and provide a CLT for the estimators of $d$. In Section 4 some Monte-Carlo experiments are presented in order to support our theoretical claims. The Nile River data and two Internet traffic packet counts datasets collected from the University of North Carolina, Chapel are studied as an application in Section 5. Sections 6 and 7 detail the proofs of the theoretical results stated in Section 3.
2. Definition of the wavelet-based regression estimators of the memory parameter $d$.

2.1. The wavelet setting. The wavelet setting involves two functions $\phi$ and $\psi$ in $L^2(\mathbb{R})$ and their Fourier transforms

$$
\hat{\phi}(\xi) \overset{\text{def}}{=} \int_{-\infty}^{\infty} \phi(t) e^{-i \xi t} \, dt \quad \text{and} \quad \hat{\psi}(\xi) \overset{\text{def}}{=} \int_{-\infty}^{\infty} \psi(t) e^{-i \xi t} \, dt .
$$

Assume the following:

1. $\phi$ and $\psi$ are compactly-supported, integrable, and $\hat{\phi}(0) = \int_{-\infty}^{\infty} \phi(t) \, dt = 1$ and $\int_{-\infty}^{\infty} \psi^2(t) \, dt = 1$.

2. There exists $\alpha > 1$ such that $\sup_{\xi \in \mathbb{R}} |\hat{\psi}(\xi)| (1 + |\xi|)^\alpha < \infty$.

3. The function $\psi$ has $M$ vanishing moments, i.e. $\int_{-\infty}^{\infty} t^m \psi(t) \, dt = 0$ for all $m = 0, \ldots, M - 1$.

4. The function $\sum_{k \in \mathbb{Z}} k^m \phi(\cdot - k)$ is a polynomial of degree $m$ for all $m = 0, \ldots, M - 1$.

Condition (W-2) ensures that the Fourier transform $\hat{\psi}$ decreases quickly to zero. Condition (W-3) ensures that $\psi$ oscillates and that its scalar product with continuous-time polynomials up to degree $M - 1$ vanishes. It is equivalent to asserting that the first $M - 1$ derivatives of $\hat{\psi}$ vanish at the origin and hence

$$
|\hat{\psi}(\lambda)| = O(|\lambda|^M) , \text{ as } \lambda \to 0 .
$$

Daubechies wavelets (with $M \geq 2$) and the Coiflets satisfy these conditions, see [19]. Viewing the wavelet $\hat{\psi}(t)$ as a basic template, define the family $\{\psi_{j,k}, j \in \mathbb{Z}, k \in \mathbb{Z}\}$ of translated and dilated functions

$$
\psi_{j,k}(t) = 2^{-j/2} \psi(2^{-j} t - k), \quad j \in \mathbb{Z}, k \in \mathbb{Z} .
$$

Positive values of $k$ translate $\psi$ to the right, negative values to the left. The scale index $j$ dilates $\psi$ so that large values of $j$ correspond to coarse scales and hence to low frequencies.

We suppose throughout the paper that

$$
(1 + \beta)/2 - \alpha < d \leq M .
$$

We now describe how the wavelet coefficients are defined in discrete time, that is for a real-valued sequence $\{x_k, k \in \mathbb{Z}\}$ and for a finite sample $\{x_k, k = 1, \ldots, n\}$. Using the scaling function $\phi$, we first interpolate these discrete values to construct the following continuous-time functions

$$
x_n(t) \overset{\text{def}}{=} \sum_{k=1}^{n} x_k \phi(t - k) \quad \text{and} \quad x(t) \overset{\text{def}}{=} \sum_{k \in \mathbb{Z}} x_k \phi(t - k), \quad t \in \mathbb{R} .
$$
Without loss of generality we may suppose that the support of the scaling function $\phi$ is included in $[-T,0]$ for some integer $T \geq 1$. Then

$$x_n(t) = x(t) \quad \text{for all} \quad t \in [0, n - T + 1].$$

We may also suppose that the support of the wavelet function $\psi$ is included in $[0,T]$. With these conventions, the support of $\psi_{j,k}$ is included in the interval $[2^j k, 2^j (k + T)]$. The wavelet coefficient $W_{j,k}$ at scale $j \geq 0$ and location $k \in \mathbb{Z}$ is formally defined as the scalar product in $L^2(\mathbb{R})$ of the function $t \mapsto x(t)$ and the wavelet $t \mapsto \psi_{j,k}(t)$:

$$W_{j,k} \overset{\text{def}}{=} \int_{-\infty}^{\infty} x(t) \psi_{j,k}(t) \, dt = \int_{-\infty}^{\infty} x_n(t) \psi_{j,k}(t) \, dt, \quad j \geq 0, k \in \mathbb{Z}, \tag{9}$$

when $[2^j k, 2^j (k + T)] \subseteq [0, n - T + 1]$, that is, for all $(j, k) \in \mathcal{I}_n$, where

$$\mathcal{I}_n \overset{\text{def}}{=} \{(j, k) : j \geq 0, 0 \leq k \leq n_j - 1\} \quad \text{with} \quad n_j = 2^{-j} (n - T + 1) - T + 1. \tag{10}$$

If $\Delta^M X$ is stationary, then from [20, Eq (17)] the process $\{W_{j,k} \}_{k \in \mathbb{Z}}$ of wavelet coefficients at scale $j \geq 0$ is stationary but the two-dimensional process $\{[W_{j,k}, W_{j',k}]^T \}_{k \in \mathbb{Z}}$ of wavelet coefficients at scales $j$ and $j'$, with $j \geq j'$, is not stationary. Here $T$ denotes the transposition. This is why we consider instead the stationary between-scale process

$$\{[W_{j,k}, W_{j,k}(j-j')^T]^T \}_{k \in \mathbb{Z}}, \tag{11}$$

where $W_{j,k}(j-j')$ is defined as follows:

$$W_{j,k}(j-j') \overset{\text{def}}{=} \begin{bmatrix} W_{j,2j-j'k}, W_{j,2j-j'k+1}, \ldots, W_{j,2j-j'k+2j-j'-1} \end{bmatrix}^T. \tag{12}$$

For all $j, j' \geq 1$, the covariance function of the between scale process is given by

$$\text{Cov}(W_{j,k'}, (j-j'), W_{j,k}) = \int_{-\pi}^{\pi} e^{i(k-k')} D_{j,j-j'}(\lambda; f) \, d\lambda, \tag{13}$$

where $D_{j,j-j'}(\lambda; f)$ stands for the cross-spectral density function of this process. For further details, we refer the reader to [20, Corollary 1]. The case $j = j'$ corresponds to the spectral density function of the within-scale process $\{W_{j,k} \}_{k \in \mathbb{Z}}$.

In the sequel, we shall use that the within- and between-scale spectral densities $D_{j,j-j'}(\lambda; d)$ of the wavelet coefficients of the process $X$ with memory parameter $d \in \mathbb{R}$ can be approximated by the corresponding spectral density of the generalized fractional Brownian motion $B_d$ defined, for $d \in \mathbb{R}$ and $u \in \mathbb{N}$, by

$$D_{\infty,u}(\lambda; d) = \left[ D_{\infty,u}^{(0)}(\lambda; d), \ldots, D_{\infty,u}^{(2u-1)}(\lambda; d) \right]$$

$$= \sum_{l \in \mathbb{Z}} |\lambda + 2l\pi|^{-2d} e_u(\lambda + 2l\pi) \hat{\psi}(\lambda + 2l\pi) \hat{\psi}(2^{-u}(\lambda + 2l\pi)), \tag{13}$$
where,
\[ e_u(\xi) \overset{\text{def}}{=} 2^{-u/2} [1, e^{-i2^{-u}\xi}, \ldots, e^{-i(2^{-u}-1)2^{-u}\xi}]^T, \quad \xi \in \mathbb{R}. \]

For further details, see [19, p. 307], Theorem 1 and Remark 5 of [20].

2.2. Definition of the robust estimators of \( d \). Let us now define robust estimators of the memory parameter \( d \) of the M(\( d \)) process \( X \) from the observations \( X_1, \ldots, X_n \). These estimators are derived from the construction of [1], and consists in regressing estimators of the scale spectrum
\[ \sigma_j^2 \overset{\text{def}}{=} \text{Var}(W_{j,0}) \]
with respect to the scale index \( j \). The idea behind such a choice is that by [19, Eq. (28)],
\[ \sigma_j^2 \sim C 2^{2jd}, \quad \text{as} \ j \to \infty, \]
where \( C \) is a positive constant. More precisely, if \( \hat{\sigma}_j^2 \) is an estimator of \( \sigma_j^2 \) based on \( W_{j,0:n_j-1} = (W_{j,0}, \ldots, W_{j,n_j-1}) \) then an estimator of the memory parameter \( d \) is obtained by regressing \( \log(\hat{\sigma}_j^2) \) for a finite number of scale indices \( j \) in \( \{J_0, \ldots, J_0+\ell\} \) where \( J_0 = J_0(n) \geq 0 \) is the lower scale and \( 1 + \ell \geq 2 \) is the number of scales in the regression. The regression estimator can be expressed formally as
\[ \hat{d}_n(J_0, w) \overset{\text{def}}{=} \sum_{j=J_0}^{J_0+\ell} w_{j-J_0} \log(\hat{\sigma}_j^2), \]
where the vector \( w = [w_0, \ldots, w_\ell]^T \) of weights satisfies \( \sum_{i=0}^\ell w_i = 0 \) and \( 2 \log(2) \sum_{i=0}^\ell iw_i = 1 \), see [1] and [20]. For \( J_0 \geq 1 \) and \( \ell > 1 \), one may choose for example \( w \) corresponding to the least squares regression matrix, defined by \( w = D(B^TDB)^{-1}b \) where
\[ b = \begin{bmatrix} 0 & (2\log(2))^{-1} \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 0 & 1 & \cdots & \ell \end{bmatrix}^T \]
is the design matrix and \( D \) is an arbitrary positive definite matrix. The best choice of \( D \) depends on the memory parameter \( d \). However a good approximation of this optimal matrix \( D \) is the diagonal matrix with diagonal entries \( D_{i,i} = 2^{-i}, \ i = 0, \ldots, \ell; \) see [13] and the references therein. We will use this choice of the design matrix in the numerical experiments.

In the sequel, we shall consider three different estimators of \( d \) based on three different estimators of the scale spectrum \( \sigma_j^2 \) with respect to the scale index \( j \) which are defined below.
2.2.1. Classical scale estimator. This estimator has been considered in the original contribution of [1] and consists in estimating the scale spectrum $\sigma_j^2$ with respect to the scale index $j$ by the empirical variance

$$\hat{\sigma}_{CL,j}^2 = \frac{1}{n_j} \sum_{i=1}^{n_j} W_{j,i}^2 , \quad (18)$$

where for any $j$, $n_j$ denotes the number of available wavelet coefficients at scale index $j$ defined in [10].

2.2.2. Median absolute deviation. This estimator is well-known to be a robust estimator of the scale and as mentioned by [27] it has several appealing properties: it is easy to compute and has the best possible breakdown point (50%). Since the wavelet coefficients $W_{j,i}$ are centered Gaussian observations, the square of the median absolute deviation of $W_{j,0:n_j-1}$ is defined by

$$\hat{\sigma}_{MAD,j}^2 = \left( m(\Phi) \text{ med}_{0 \leq i \leq n_j-1} |W_{j,i}| \right)^2 , \quad (19)$$

where $\Phi$ denotes the c.d.f of a standard Gaussian random variable and

$$m(\Phi) = 1/\Phi^{-1}(3/4) = 1.4826 . \quad (20)$$

The use of the median estimator to estimate the scalogram has been suggested to estimate the memory parameter in [29] (see also [24, p. 420]). A closely related technique is considered in [9] and [10] to estimate the Hurst coefficient of locally self-similar Gaussian processes. Note that the use of the median of the squared wavelet coefficients has been advocated to estimate the variance at a given scale in wavelet denoising applications; this technique is mentioned in [12] to estimate the scalogram of the noise in the i.i.d. context; [15] proposed to use this method in the long-range dependent context; the use of these estimators has not been however rigorously justified.

2.2.3. The Croux and Rousseeuw estimator. This estimator is another robust scale estimator introduced in [27]. Its asymptotic properties in several dependence contexts have been further studied in [16] and the square of this estimator is defined by

$$\hat{\sigma}_{CR,j}^2 = \left( c(\Phi) \{ |W_{j,i} - W_{j,k}|; \ 0 \leq i, k \leq n_j - 1 \}_{(k_{n_j})} \right)^2 , \quad (21)$$

where $c(\Phi) = 2.21914$ and $k_{n_j} = \lceil n_j^2/4 \rceil$. That is, up to the multiplicative constant $c(\Phi)$, $\hat{\sigma}_{CR,j}$ is the $k_{n_j}$th order statistics of the $n_j^2$ distances $|W_{j,i} - W_{j,k}|$ between all the pairs of observations.
3. Asymptotic properties of the robust estimators of $d$

3.1. Properties of the scale spectrum estimators. The following proposition gives an asymptotic expansion for $\hat{\sigma}_{CL,j}^2$, $\hat{\sigma}_{MAD,j}^2$ and $\hat{\sigma}_{CR,j}^2$ defined in (18), (19) and (21), respectively. These asymptotic expansions are used for deriving Central Limit Theorems for the different estimators of $d$.

**Proposition 1.** Assume that $X$ is a Gaussian $M(d)$ process with generalized spectral density function defined in (2) such that $f^* \in \mathcal{H}(\beta, L)$ for some $L > 0$ and $0 < \beta \leq 2$. Assume that $(W-I), (W-4)$ hold with $d, \alpha$ and $M$ satisfying (7). Let $W_{j,k}$ be the wavelet coefficients associated to $X$ defined by (17). If $n \to J_0(n)$ is an integer valued sequence satisfying $J_0(n) \to \infty$ and $n^{2-J_0(n)} \to \infty$, as $n \to \infty$, then $\hat{\sigma}_{*j}^2$ defined in (18), (19) and (21), satisfies the following asymptotic expansion, as $n \to \infty$, for any given $\ell \geq 1$

$$
\max_{J_0(n) \leq j \leq J_0(n)+\ell} \left| \sqrt{n_j} (\hat{\sigma}_{*j}^2 - \sigma_j^2) - 2 \sigma_j \sum_{i=0}^{n_j-1} \text{IF} \left( \frac{W_j i}{\sigma_j \Phi} \right) \right| = o_P(1),
$$

where $\ast$ denotes CL, CR and MAD, $\sigma_j^2$ is defined in (14) and IF is given by

$$
\text{IF} (x, CL, \Phi) = \frac{1}{2} H_2(x),
$$

$$
\text{IF} (x, CR, \Phi) = c(\Phi) \left( \frac{1}{2} - \Phi(x + 1/c(\Phi)) + \Phi(x - 1/c(\Phi)) \right),
$$

$$
\text{IF} (x, MAD, \Phi) = -m(\Phi) \left( \frac{1}{2} - \Phi(x/m(\Phi)) \right),
$$

where $\varphi$ denotes the p.d.f of the standard Gaussian random variable, $m(\Phi)$ and $c(\Phi)$ being defined in (20) and (21), respectively and $H_2(x) = x^2 - 1$ is the second Hermite polynomial.

The proof is postponed to Section 6.

We deduce from Proposition 1 and Theorem 2 given and proved in Section 6 the following multivariate Central Limit Theorem for the wavelet coefficient scales.

**Theorem 2.** Under the assumptions of Proposition 1, $$(\hat{\sigma}_{*j_0}^2, \ldots, \hat{\sigma}_{*j_0+\ell}^2)^T$$, where $\hat{\sigma}_{*j}^2$ is defined in (18), (19) and (21), satisfies the following multivariate Central Limit Theorem

$$
\sqrt{n^{2-J_0} 2^{-2J_0d}} \left( \begin{array}{c} \hat{\sigma}_{*j_0}^2 \\ \hat{\sigma}_{*j_0+1}^2 \\ \vdots \\ \hat{\sigma}_{*j_0+\ell}^2 \\ \end{array} \right) \xrightarrow{d} \mathcal{N} (0, U_*(d)),
$$

where
where

\[ U_{*,i,j}(d) = 4(f^*(0))^2 \sum_{p \geq 2} \frac{c_p(\text{IF}_*)}{p! K(d)^p} 2^{d(2+p)i+j} 2^{d(2-p)i+j + 4d(i,j)} \]

\[ \times \sum_{\tau \in \mathbb{Z}} \sum_{r=0}^{2|i-j|-1} \left( \int_{-\pi}^{\pi} D_{\infty,i-j}(\lambda;d) e^{i \lambda \tau} d\lambda \right)^p, \quad 0 \leq i, j \leq \ell. \quad (27) \]

In (27), \( K(d) \) is defined as the cross-spectral density defined in (13), \( c_p(\text{IF}_*) = \mathbb{E}[\text{IF}(X,*,\Phi)H_p(X)] \), where \( H_p \) is the \( p \)th Hermite polynomial and \( \text{IF}(\cdot,*,\Phi) \) is defined in (23), (24) and (25).

The proof of Theorem 2 is postponed to Section 6.

**Remark 1.** Since for \( * = \text{CL} \), \( \text{IF}(\cdot) = H_2(\cdot)/2 \), Theorem 2 gives an alternative proof to [19, Theorem 2] of the limiting covariance matrix of \( (\hat{\sigma}_{*,J_0}^2, \ldots, \hat{\sigma}_{*,J_0+\ell}^2)^T \) which is given, for \( 0 \leq i, j \leq \ell \), by

\[ U_{\text{CL},i,j}(d) = 4\pi (f^*(0))^2 2^{4d(i,j)+i+j} \int_{-\pi}^{\pi} |D_{\infty,i-j}(\lambda;d)|^2 d\lambda. \]

Thus, for \( * = \text{CR} \) and \( * = \text{MAD} \), we deduce the following

\[ \frac{U_{\text{CL},i,i}(d)}{U_{*,i,i}(d)} > \frac{1/2}{\mathbb{E}[\text{IF}^2_*(Z)]}, \quad (28) \]

where \( Z \) is a standard Gaussian random variable. With Lemma 8, we deduce from the inequality (28) that the asymptotic relative efficiency of \( \hat{\sigma}_{*,j}^2 \) is larger than 36.76% when \( * = \text{MAD} \) and larger than 82.27% when \( * = \text{CR} \).

3.2. CLT for the robust wavelet-based regression estimator. Based on the results obtained in the previous section, we derive a Central Limit Theorem for the robust wavelet-based regression estimators of \( d \) defined by

\[ \hat{d}_{*,n}(J_0, w) \] def \[ = J_0 + \ell \sum_{j=J_0}^{J_0+\ell} w_j - J_0 \log (\hat{\sigma}_{*,j}^2) \],

where \( \hat{\sigma}_{*,j}^2 \) are given for \( * = \text{CL} \), \( \text{MAD} \) and \( \text{CR} \) by (18), (19) and (21), respectively.

**Theorem 3.** Under the same assumptions as in Proposition 4 and if

\[ n 2^{-(1+2\beta)J_0(n)} \to 0, \quad \text{as} \quad n \to \infty, \quad (30) \]

then, \( \hat{d}_{*,n}(J_0, w) \) satisfies the following Central Limit Theorem:

\[ \sqrt{n 2^{-J_0(n)}} \left( \hat{d}_{*,n}(J_0, w) - d \right) \overset{d}{\to} \mathcal{N}(0, w^T \mathbf{V}_*(d) w), \quad (31) \]
where $V_*(d)$ is the $(1+\ell) \times (1+\ell)$ matrix defined by

$$V_{*,i,j}(d) = \sum_{p \geq 2} \frac{4^{p-1}c_p(|\widehat{IF}_*|)}{p!K(d)^p} 2^{p(|d|-j)+i} \sum_{\tau \in \mathbb{Z}} 2^{2|\tau|-j-1} \left( \int_{-\pi}^{\pi} D_{\infty,|\tau|-j}^{(r)}(\lambda; d)e^{i\lambda \tau}d\lambda \right)^p, \quad 0 \leq i,j \leq \ell. \quad (32)$$

In [52], $K(d) = \int_{\mathbb{R}} |\xi|^{-2d} |\hat{\psi}(\xi)|d\xi$, $D_{\infty,|\tau|-j}(\cdot; d)$ is the cross-spectral density defined in [13], $c_p(|\widehat{IF}_*|) = E[|IF(X,*,\Phi)H_p(X)|]$, where $H_p$ is the $p$th Hermite polynomial and $IF(\cdot,*,\Phi)$ is defined in [23], [24] and [25].

The proof of Theorem 3 follows from Theorem 2 and the Delta method as explained in the proof of [10, Proposition 3].

**Remark 2.** Since it is difficult to provide a theoretical lower bound for the asymptotic relative efficiency (ARE) of $\hat{\alpha}_{*,n}(J_0,w)$ defined by

$$ARE_*(d) = w^T V_{\text{CL}}(d)w / w^T V_*(d)w, \quad (33)$$

where $\ast = \text{CR or MAD}$, we propose to compute this quantity empirically. We know from Theorem 3 that the expression of the limiting variance $w^T V_*(d)w$ is valid for all Gaussian $M(d)$ processes satisfying the assumptions given in Proposition 7, thus it is enough to compute $ARE_*(d)$ in the particular case of a Gaussian ARFIMA(0,d,0) process $(X_t)$. Such a process is defined by

$$X_t = (I - B)^{-d}Z_t = \sum_{j \geq 0} \frac{\Gamma(j + d)}{\Gamma(j + 1)\Gamma(d)} Z_{t-j}, \quad (34)$$

where $\{Z_t\}$ are i.i.d $N(0,1)$. We propose to evaluate $ARE_*(d)$ empirically by simulating several Gaussian ARFIMA(0,d,0) processes for each $d$ belonging to $[-0.8; 3]$ and computing the associated empirical standard error. With such a choice of $d$, both stationary and non-stationary processes are considered. The empirical values of $ARE_*(d)$ are given in Table 1. The results were obtained from the observations $X_1, \ldots, X_n$ where $n = 2^{12}$, 1000 independent replications and $w = DB((B^TDB)^{-1})b$, where $B$ and $b$ are defined in [17] and $D$ is a diagonal matrix with diagonal coefficients $D_{ii} = 2^{-i}$. We used Daubechies wavelets with $M = 2$ vanishing moments when $d \leq 2$ and $M = 4$ when $d > 2$ which ensures that condition [4] is satisfied. The smallest scale is chosen to be $J_0 = 3$ and $J_0 + \ell = 8$.

| $d$   | -0.8 | -0.4 | -0.2 | 0  | 0.2 | 0.6 | 0.8 | 1  | 1.2 | 1.6 | 2  | 2.2 | 2.6 | 3  |
|-------|------|------|------|----|----|----|----|----|----|----|----|----|----|----|
| ARE_{\text{CR}}(d) | 0.72 | 0.67 | 0.63 | 0.65 | 0.70 | 0.63 | 0.70 | 0.75 | 0.76 | 0.75 | 0.79 | 0.74 | 0.77 | 0.74 |
| ARE_{\text{MAD}}(d) | 0.48 | 0.39 | 0.38 | 0.36 | 0.43 | 0.39 | 0.44 | 0.47 | 0.45 | 0.50 | 0.48 | 0.5  | 0.49 | 0.49 |

| Table 1. Asymptotic relative efficiency of $d_{n,\text{CR}}$ and $d_{n,\text{MAD}}$ with respect to $d_{n,\text{CL}}$. |
From Table 1, we can see that \( \hat{d}_{n,\text{CR}} \) is more efficient than \( \hat{d}_{n,\text{MAD}} \) and that its asymptotic relative efficiency ARE \( \text{CR} \) ranges from 0.63 to 0.79. These results indicate empirically that the loss of efficiency of the robust estimator \( \hat{d}_{n,\text{CR}} \) is moderate and makes it an attractive robust procedure to the non-robust estimator \( \hat{d}_{n,\text{CL}} \).

4. Numerical experiments

In this section the robustness properties of the different estimators of \( d \), namely \( \hat{d}_{n,\text{CL}}(J_0, w) \), \( \hat{d}_{n,\text{CR}}(J_0, w) \) and \( \hat{d}_{n,\text{MAD}}(J_0, w) \), that are defined in Section 2.2 are investigated using Monte Carlo experiments. In the sequel, the memory parameter \( d \) is estimated from \( n = 2^{12} \) observations of a Gaussian ARFIMA(0,\( d \),0) process defined in (34) when \( d = 0.2 \) and 1.2 eventually corrupted by additive outliers. We use the Daubechies wavelets with \( M = 2 \) vanishing moments which ensures that condition (7) is satisfied.

Let us first explain how to choose the parameters \( J_0 \) and \( J_0 + \ell \). With \( n = 2^{12} \), the maximal available scale is equal to 10. Choosing \( J_0 \) too small may introduce a bias in the estimation of \( d \) by Theorem 3. However, at coarse scales (large values of \( J_0 \)), the number of observations may be too small and thus choosing \( J_0 \) too large may yield a large variance. Since at scales \( j = 9 \) and \( j = 10 \), we have respectively 5 and 1 observations, we chose \( J_0 + \ell = 8 \). For the choice of \( J_0 \), we use the empirical rule proposed by [19] and illustrated in Figure 1. In this figure, we display the estimates \( \hat{d}_{n,\text{CL}}, \hat{d}_{n,\text{CR}} \) and \( \hat{d}_{n,\text{MAD}} \) of the memory parameter \( d \) as well as their respective 95% confidence intervals from \( J_0 = 1 \) to \( J_0 = 7 \) with \( J_0 + \ell = 8 \). We propose to choose \( J_0 = 3 \) in both cases (\( d = 0.2 \) and \( d = 1.2 \)) since the successive confidence intervals starting from \( J_0 = 3 \) to \( J_0 = 7 \) are such that the smallest one is included in the largest one. This choice is a way to achieve a bias/variance trade-off. A further justification for this choice of \( J_0 \) is given in Table 2 in which we provide the empirical coverage probabilities associated to \( \hat{d}_{n,\text{CL}}(J_0, w) \) which correspond to the probability that \( d \) belongs to the 95% confidence intervals. Note that the confidence intervals in Figure 1 were computed by using Theorem 3. More precisely, an approximation of the limiting variance is obtained by computing the empirical standard error of \( \sqrt{n2^{-J_0}}(\hat{d}_{n,\text{CL}}(J_0, w) - d) \) for the different values of \( J_0 \) by simulating and estimating the memory parameter of 5000 Gaussian ARFIMA(0,\( d \),0) processes with \( d = 0.2 \) (left part of Figure 1) and with \( d = 1.2 \) (right part of Figure 1).

In the left panels of Figures 2 and 3 the empirical distribution of \( \sqrt{n2^{-J_0}}(\hat{d}_{n,\text{CL}} - d) \) are displayed when \( * = \text{CL}, \text{MAD} \) and \( \text{CR} \) for the ARFIMA(0,\( d \),0) model with \( d = 0.2 \) (Figure 2) and \( d = 1.2 \) (Figure 3), respectively. They were computed using 5000 replications; their shapes are close to the Gaussian density (the standard deviations are of course different).
In the right panels of Figures 2 and 3, the empirical distribution of $\sqrt{n^{2-J_0}}(\hat{d}_{\text{CL},n} - d)$ are displayed when outliers are present. We introduce 1% of additive outliers in the observations; these outliers are obtained by choosing uniformly at random a time index and by adding to the selected observation 5 times the standard error of the raw observations. The empirical distribution of $\sqrt{n^{2-J_0}}(\hat{d}_{\text{CL},n} - d)$ is clearly located far away from zero especially in the nonstationary ARFIMA$(0, 1.2, 0)$ model. One can also observe the considerable increase in the variance of the classical estimator. In sharp contrast, the distribution of the robust estimators $\sqrt{n^{2-J_0}}(\hat{d}_{\text{MAD},n} - d)$ and $\sqrt{n^{2-J_0}}(\hat{d}_{\text{CR},n} - d)$ stays symmetric and the variance stays constant.

5. Application to real Data
In this section, we compare the performance of the different estimators of the long memory parameter $d$ introduced in Section 2.2 on two different real datasets.

5.1. Nile River data. The Nile River dataset is a well-known time series, which has been extensively analyzed; see [4, Section 1.4, p. 20]. The data consists of yearly minimal water
levels of the Nile river measured at the Roda gauge, near Cairo, for the years 622–1284 AD and contains 663 observations; The units for the data as presented by [4] are centimeters. The empirical mean and the standard deviation of the data are equal to 1148 and 89.05, respectively. The question has been raised as to whether the Nile time series contains outliers; see for example [3], [25], [8] and [18]. The test procedure developed by [8] suggests the presence of outliers at 646 AD ($p$-value 0.0308) and at 809 ($p$-value 0.0007). Another possible outliers is at 878 AD. Since the number of observations is small, in the estimation of $d$, we took $J_0 = 1$ and $J_0 + \ell = 6$. With this choice, we observe a significant difference between the classical estimators $\hat{d}_{n,CL} = 0.28$ (with 95% confidence interval $[0.23, 0.32]$) and the robust estimators $\hat{d}_{n,CR} = 0.408$ (with 95% confidence interval $[0.34, 0.46]$) and $\hat{d}_{n,MAD} = 0.414$ (with 95%
confidence interval [0.34, 0.49]). Thus, to better understand the influence of outliers on the estimated memory parameter in practical situations, a new dataset with artificial outliers was generated. Here, we replaced the presumed outliers of \[8\] by the value of the observation plus 10 times the standard deviation. The new memory parameter estimators are \(\hat{d}_{n,\text{CL}} = 0.12\), \(\hat{d}_{n,\text{CR}} = 0.4\) and \(\hat{d}_{n,\text{MAD}} = 0.392\). As was expected, the values of the robust estimators remained stable. However, the classical estimator of \(d\) was significantly affected. A robust estimate of \(d\) for the Nile data is also given in [18]. The authors found 0.416 which is very close to \(\hat{d}_{n,\text{CR}} = 0.408\) and \(\hat{d}_{n,\text{MAD}} = 0.414\).

5.2. Internet traffic packet counts data. In this section, two Internet traffic packet counts datasets collected at the University of North Carolina, Chapel (UNC) are analyzed. These datasets are available from the website http://netlab.cs.unc.edu/public/old_research/net_lrd/. These datasets have been studied by [23].

Figure 4 (left) displays a packet count time series measured at the link of UNC on April 13, Saturday, from 7:30 p.m. to 9:30 p.m., 2002 (Sat1930). Figure 4 (right) displays the same type of time series but on April 11, a Thursday, from 1 p.m. to 3 p.m., 2002 (Thu1300). These packet counts were measured every 1 millisecond but, for a better display, we aggregated them at 1 second.

The maximal available scale for the two datasets is 20. Since we have less than 4 observations at this scale, we set the coarse scale \(J_0 + \ell = 19\) and vary the finest scale \(J_0\) from 1 to 17. The values of the three estimators of \(d\) are stored in Table 3 for \(J_0 = 1\) to 14 as well as the standard errors of \(\sqrt{n}2^{-J_0}(\hat{d}_{n,*} - d)\) for the two datasets: Thu1300 and Sat1930. The standard errors in Table 3 were obtained as follows. For each estimated value of \(d\), we simulated \(n\) observations of 1000 Gaussian ARFIMA(0,\(d\),0) processes with this value of \(d\), \(n\) being the number of observations of the datasets that we are studying (Thu1300 or Sat1930).
and we computed the empirical standard errors of $\sqrt{n^{2-J_0}(\hat{d}_{n,*} - d)}$ from these 1000 Gaussian ARFIMA$(0,d,0)$ processes.

In Figure 5, we display the estimates $\hat{d}_{n,\text{CL}}$, $\hat{d}_{n,\text{CR}}$ and $\hat{d}_{n,\text{MAD}}$ of the memory parameter $d$ as well as their respective 95% confidence intervals from $J_0 = 1$ to $J_0 = 14$. We propose to choose $J_0 = 9$ for Thu1300 and $J_0 = 10$ for Sat1930 since from these values of $J_0$ the successive confidence intervals are such that the smallest one is included in the largest one (for the robust estimators). Note that [23] chose the same values of $J_0$ using another methodology. For these values of $J_0$ we obtain $\hat{d}_{n,\text{CL}} = 0.43$ (with 95% confidence interval $[0.412, 0.443]$), $\hat{d}_{n,\text{CR}} = 0.37$ (with 95% confidence interval $[0.358, 0.385]$) and $\hat{d}_{n,\text{MAD}} = 0.38$ (with 95% confidence interval $[0.362, 0.397]$) for Thu1300 and $\hat{d}_{n,\text{CL}} = 0.36$ (with 95% confidence interval $[0.345, 0.374]$), $\hat{d}_{n,\text{CR}} = \hat{d}_{n,\text{MAD}} = 0.38$ (with 95% confidence intervals $[0.361, 0.398]$ for CR and $[0.357, 0.402]$ for MAD) for Sat1930. These values are similar to the one found by [23].

With this choice of $J_0$ for Thu1300, we observe a significant difference between the classical estimator and the robust estimators. Thus to better understand the influence of outliers on the estimated memory parameter a new dataset with artificial outliers was generated. The Thu1300 time series shows two spikes shooting down. Especially, the first downward spike hits zero. [22] have shown that this dropout lasted 8 seconds. Outliers are introduced by dividing by 6 the 8000 observations in this period. The new memory parameter estimators are $\hat{d}_{n,\text{CL}} = 0.445$, $\hat{d}_{n,\text{CR}} = 0.375$ and $\hat{d}_{n,\text{MAD}} = 0.377$. As for the Nile River data, the classical estimator was affected while the robust estimators remain stable.

In Figure 5 we display the estimates $\hat{d}_{n,\text{CL}}, \hat{d}_{n,\text{CR}}$ and $\hat{d}_{n,\text{MAD}}$ of the memory parameter $d$ as well as their respective 95% confidence intervals from $J_0 = 1$ to $J_0 = 14$. We propose to choose $J_0 = 9$ for Thu1300 and $J_0 = 10$ for Sat1930 since from these values of $J_0$ the successive confidence intervals are such that the smallest one is included in the largest one (for the robust estimators). Note that [23] chose the same values of $J_0$ using another methodology. For these values of $J_0$ we obtain $\hat{d}_{n,\text{CL}} = 0.43$ (with 95% confidence interval $[0.412, 0.443]$), $\hat{d}_{n,\text{CR}} = 0.37$ (with 95% confidence interval $[0.358, 0.385]$) and $\hat{d}_{n,\text{MAD}} = 0.38$ (with 95% confidence interval $[0.362, 0.397]$) for Thu1300 and $\hat{d}_{n,\text{CL}} = 0.36$ (with 95% confidence interval $[0.345, 0.374]$), $\hat{d}_{n,\text{CR}} = \hat{d}_{n,\text{MAD}} = 0.38$ (with 95% confidence intervals $[0.361, 0.398]$ for CR and $[0.357, 0.402]$ for MAD) for Sat1930. These values are similar to the one found by [23].

With this choice of $J_0$ for Thu1300, we observe a significant difference between the classical estimator and the robust estimators. Thus to better understand the influence of outliers on the estimated memory parameter a new dataset with artificial outliers was generated. The Thu1300 time series shows two spikes shooting down. Especially, the first downward spike hits zero. [22] have shown that this dropout lasted 8 seconds. Outliers are introduced by dividing by 6 the 8000 observations in this period. The new memory parameter estimators are $\hat{d}_{n,\text{CL}} = 0.445$, $\hat{d}_{n,\text{CR}} = 0.375$ and $\hat{d}_{n,\text{MAD}} = 0.377$. As for the Nile River data, the classical estimator was affected while the robust estimators remain stable.

Table 3: Estimators of $d$ with $J_0 = 1$ to $J_0 = 14$ and $J_0 + \ell = 19$ obtained from Thu1300 and Sat1930. Here SE denotes the standard error of $\sqrt{n^{2-J_0}(\hat{d}_{n,*} - d)}$. 
6. Proofs

Theorem 4 is an extension of [2, Theorem 4] to arrays of stationary Gaussian processes in the unidimensional case and Theorem 5 extends the result of [11] to arrays of stationary Gaussian processes. These two theorems are useful for the proof of Proposition 1.

Theorem 4. Let \{X_{j,i}, j \geq 1, i \geq 0\} be an array of standard stationary Gaussian processes such that for a fixed \(j \geq 1\), \((X_{j,i})_{i\geq 0}\) has a spectral density \(f_j\) and an autocorrelation function \(\rho_j\) defined by \(\rho_j(k) = \mathbb{E}(X_{j,0}X_{j,k})\), for all \(k \geq 0\). Assume also that there exists a sequence \(\{u_j\}_{j \geq 1}\) tending to zero as \(j\) tends to infinity such that for all \(j \geq 1\)

\[
\sup_{\lambda \in (-\pi, \pi)} |f_j(\lambda) - g_\infty(\lambda)| \leq u_j,
\]

(35)

where \(g_\infty\) is a 2\(\pi\)-periodic function which is bounded on \((-\pi, \pi)\) and continuous at the origin. Let \(h\) be a function on \(\mathbb{R}\) such that \(\mathbb{E}[h(X)^2] < \infty\), where \(X\) is a standard Gaussian random variable, and of Hermite rank \(\tau \geq 1\). Let \(\{n_j\}_{j \geq 1}\) be a sequence of integers such that \(n_j\) tends to infinity as \(j\) tends to infinity. Then,

\[
\frac{1}{\sqrt{n_j}} \sum_{i=1}^{n_j} h(X_{j,i}) \xrightarrow{d} \mathcal{N}(0, \tilde{\sigma}^2), \quad \text{as } j \to \infty,
\]

(36)

where

\[
\tilde{\sigma}^2 = \lim_{j \to \infty} \text{Var} \left( \frac{1}{\sqrt{n_j}} \sum_{i=1}^{n_j} h(X_{j,i}) \right) = 2\pi \sum_{\ell \geq \tau} \frac{c_{\ell}^2}{\ell!} g_\infty^{*}(0).
\]

In the previous equality, \(c_\ell = \mathbb{E}[h(X)H_\ell(X)]\), where \(H_\ell\) is the \(\ell\)-th Hermite polynomial and \(X\) is a standard Gaussian random variable.
Proof of Theorem 4. By observing that $h(x) = \sum_{t \geq t} c_t H_t(x)/\ell_t$, we start by proving that for any fixed $t$,
\[
\sum_{i=1}^{n_j} \sum_{\tau \leq \ell \leq t} \frac{c_{\ell}}{\ell^t} H_\ell(X_{\tau,j,i}) \quad \xrightarrow{d} N(0, 1), \text{ as } n_j \to \infty.
\] (37)

Using Mehler’s formula given in [6, (2.1)], we have
\[
\text{Var} \left( \sum_{i=1}^{n_j} \sum_{\tau \leq \ell \leq t} \frac{c_{\ell}}{\ell^t} H_\ell(X_{\tau,j,i}) \right) = \sum_{i_1,i_2=1}^{n_j} \sum_{\tau \leq \ell \leq t} \frac{c_{\ell_1}c_{\ell_2}}{\ell_1!\ell_2!} E [H_{\ell_1}(X_{\tau,j,i_1}) H_{\ell_2}(X_{\tau,j,i_2})]
\]
\[
= \sum_{\tau \leq \ell \leq t} \frac{c^2}{\ell^t} \left[ \sum_{i_1,i_2=1}^{n_j} \rho^\ell_{j_2} (i_2 - i_1) \right]. \quad (38)
\]

Since the Gaussian distribution is uniquely determined by its moments, it is enough to show the convergence of moments to prove (37), that is for $p \geq 1$,
\[
\frac{E \left[ \left( \sum_{i=1}^{n_j} \sum_{\tau \leq \ell \leq t} \frac{c_{\ell}}{\ell^t} H_\ell(X_{\tau,j,i}) \right)^{2p+1} \right]}{\left( \sum_{\tau \leq \ell \leq t} \frac{c^2}{\ell^t} \left[ \sum_{i_1,i_2=1}^{n_j} \rho^\ell_{j_2} (i_2 - i_1) \right] \right)^{2p+1}} \to 0, \quad \text{as } n_j \to \infty \quad \text{and} \quad (39)
\]
\[
E \left[ \left( \sum_{i=1}^{n_j} \sum_{\tau \leq \ell \leq t} \frac{c_{\ell}}{\ell^t} H_\ell(X_{\tau,j,i}) \right)^{2p} \right] \quad \text{as } n_j \to \infty. \quad (40)
\]

Observe that for all $m$ in $\mathbb{N}^*$,
\[
E \left[ \left( \sum_{i=1}^{n_j} \sum_{\tau \leq \ell \leq t} \frac{c_{\ell}}{\ell^t} H_\ell(X_{\tau,j,i}) \right)^m \right] = \sum_{1 \leq i_1, \ldots, i_m \leq n_j} \sum_{\tau \leq \ell_1, \ldots, \ell_m \leq t} \frac{c_{\ell_1} \cdots c_{\ell_m}}{\ell_1! \cdots \ell_m!} E [H_{\ell_1}(X_{\tau,i_1}) \ldots H_{\ell_m}(X_{\tau,i_m})]. \quad (41)
\]

By [26, Equation (33), p. 69],
\[
E [H_{\ell_1}(X_{\tau,i_1}) \ldots H_{\ell_m}(X_{\tau,i_m})] = \ell_1! \ldots \ell_m! \sum_{\{\ell_1, \ldots, \ell_m\}} \frac{\rho^\nu}{\nu!}, \quad (42)
\]

where it is understood that $\rho^\nu_{j_2} = \prod_{1 \leq q < k \leq m} \rho^\nu_{j_2 q k} (i_q - i_k)$, $\nu! = \prod_{1 \leq q < k \leq m} \nu_{q,k}$, and $\sum_{\{\ell_1, \ldots, \ell_m\}}$ indicates that we are to sum over all symmetric matrices $\nu$ with nonnegative integer entries, $\nu_i = 0$ and the row sums equal to $\ell_1, \ldots, \ell_m$.

1) We start with the case where $m = 2p + 1$. By Lemma 9 we get that
\[
\lim_{n_j \to \infty} \frac{1}{n_j} \sum_{\tau \leq \ell \leq t} \frac{c^2}{\ell^t} \left[ \sum_{i_1,i_2=1}^{n_j} \rho^\ell_{j_2} (i_2 - i_1) \right] = 2\pi \sum_{\tau \leq \ell \leq t} \frac{c^2}{\ell^t} g^\ell_{\infty}(0). \quad (43)
\]
Thus, in order to prove (44), it is enough to prove that
\[
\lim_{n_j \to \infty} \frac{1}{n_j^{p+1/2}} \mathbb{E} \left[ \left( \sum_{i=1}^{n_j} \sum_{\tau \leq \ell} c_{\ell}^{i} H_{\ell}(X_{j,i}) \right)^{2p+1} \right] = 0.
\] (44)

Let us now prove that
\[
\lim_{n_j \to \infty} \frac{1}{n_j^{p+1/2}} \sum_{1 \leq i_1, \ldots, i_{2p+1} \leq n_j} \sup_{\nu} \prod_{1 \leq q < k \leq 2p+1} \rho_{j}^{\nu_{q,k}}(i_q - i_k) = 0,
\] (45)

where \(\sup_{\nu}\) indicates that we are taking the supremum over all symmetric matrices \(\nu\) with nonnegative integer entries, \(\nu_{ii} = 0\) and the row sums equal to \(\ell_1, \ldots, \ell_{2p+1}\). By (11) and (12), (45) is a consequence of (44).

Let us first address the case where \(|\{i_1, \ldots, i_{2p+1}\}| = 2p+1\), that is, the indices \(i_1, \ldots, i_{2p+1}\) are all different. Using that \(\rho_{j}^{\nu_{q,k}}(i_q - i_k) \leq e_{\nu_{q,k}}(i_q - i_k) f_{j}^{\nu_{q,k}}(\lambda_q,k) d\lambda_q,k\) and the notation \(D_{n_j}(\lambda) = \sum_{r=1}^{n_j} e^{\lambda r}\), we obtain that

\[
\sum_{1 \leq i_1, \ldots, i_{2p+1} \leq n_j} \prod_{1 \leq q < k \leq 2p+1} \rho_{j}^{\nu_{q,k}}(i_q - i_k) = \int_{[-\pi,\pi]^{2p+1}} D_{n_j} \left( \sum_{k=2}^{2p+1} \lambda_{1,k} \right) D_{n_j} \left( \sum_{k=3}^{2p+1} \lambda_{2,k} \right) D_{n_j} \left( \sum_{q=1}^{2p} \lambda_{q,2p+1} \right) f_{j}^{\nu_{q,k}}(\lambda_q,k) d\lambda_q,k,
\] (46)

with the convention that \(f_{j}^{\nu_{q,k}}(\lambda)d\lambda\) is a Dirac measure at 0. The number of \(D_{n_j}\) in the previous product is equal to \(2p+1\). Since the \(\ell_i\)'s are greater than 1, there are at least one \(\lambda_{q,k}\) in each \(D_{n_j}\). Moreover, there exists at least one \(D_{n_j}\) having a sum of at least two \(\lambda_{q,k}\)'s as argument otherwise the matrix \(\nu\) would have a null line which is impossible since the \(\ell_i\)'s are greater than 1. The r.h.s of (46) can be bounded above by using that \(ab \leq (a^2 + b^2)/2\) with

\[
a = D_{n_j} \left( \sum_{k=2}^{2p+1} \lambda_{1,k} \right) \left( \sum_{k=3}^{2p+1} \lambda_{2,k} \right)^{1/2},
\]

and

\[
b = \left| D_{n_j} \left( -\lambda_{1,2} + \sum_{k=3}^{2p+1} \lambda_{2,k} \right) \right|^{1/2} D_{n_j} \left( -\lambda_{1,3} - \lambda_{2,3} + \sum_{k=4}^{2p+1} \lambda_{3,k} \right) \ldots D_{n_j} \left( -\sum_{q=1}^{2p} \lambda_{q,2p+1} \right) \right|^{1/2}.
\]

Then, using Lemma 10 and 35, we get (45). Actually, the \(D_{n_j}\) which is common to \(a\) and \(b\) can be any \(D_{n_j}\) having a sum of at least two \(\lambda_{q,k}\)'s as argument. Such a \(D_{n_j}\) does exist according to the previous remark.
If $|\{i_1, \ldots, i_{2p+1}\}| < 2p + 1$, the number of $D_{n_j}$ appearing in the r.h.s of (46) is equal to $|\{i_1, \ldots, i_{2p+1}\}|$ and thus using the same arguments as previously, we can also conclude in this case that (45) holds.

2) Let us now study the case where $m$ is even that is $m = 2p$ with $p \geq 1$.

We shall prove that among all the terms in the r.h.s of (42), the leading ones correspond to the case where we have $p$ pairs of equal indices in the set $\{\ell_1, \ldots, \ell_{2p}\}$, that is, for instance, $\ell_1 = \ell_2$, $\ell_3 = \ell_4, \ldots, \ell_{2p-1} = \ell_{2p}$ and $\nu_{1,2} = \ell_1$, $\nu_{3,4} = \ell_3, \ldots, \nu_{2p-1,2p} = \ell_{2p-1}$ the others $\nu_{i,j}$ being equal to zero. This gives

$$(\ell_2!)^2 \cdots (\ell_{2p}!)^2 \rho_j(i_2 - i_1)\rho_j(i_4 - i_3)\cdots \rho_j(i_{2p} - i_{2p-1})\ell_2! \cdots \ell_{2p}!$$

The corresponding term in (41) with $m = 2p$ is given by

$$\sum_{1 \leq i_1, \ldots, i_{2p} \leq n_j} \sum_{\tau \leq \ell_2, \ell_4, \ldots, \ell_{2p} \leq \ell} \frac{c_{\ell_2}^2 c_{\ell_4}^2 \cdots c_{\ell_{2p}}^2}{\rho_j(i_2 - i_1)\rho_j(i_4 - i_3)\cdots \rho_j(i_{2p} - i_{2p-1})\ell_2! \cdots \ell_{2p}!} = \left[\sum_{l \geq \tau} \frac{c_l^2}{\ell_l!} \left( \sum_{i_1, i_2 = 1}^{n_j} \rho_k^l (i_2 - i_1) \right) \right]^p,$$

which corresponds to the denominator in the l.h.s of (40). Since there exists exactly $(2p)!/(2^p p!)$ possibilities to have pairs of equal indices among $2p$ indices we obtain (40) if we prove that the other terms can be neglected.

We use the same line of reasoning as the one used in the case where $m$ is odd and prove that

$$\lim_{n_j \to \infty} \frac{1}{n_j^{2p}} \sum_{1 \leq i_1, \ldots, i_{2p} \leq n_j} \sup_{\nu} \prod_{1 \leq q < k \leq 2p} \rho_j^{\nu_q, k} (i_q - i_k) = 0,$$

where $\sup_{\nu}$ indicates that we are taking the supremum over all symmetric matrices $\nu$ with nonnegative integer entries such that $\nu_{ii} = 0$, the row sums equal to $\ell_1, \ldots, \ell_{2p}$ and such that there are at least two non null values of $\nu_{qk}$ on a row of $\nu$.

Let us first address the case where $|\{i_1, \ldots, i_{2p}\}| = 2p$. Using the notation $D_{n_j}(\lambda) = \sum_{r=1}^{n_j} e^{i \lambda r}$ and that $\rho_j^{\nu_q, k} (i_q - i_k) = \int_{-\pi}^{\pi} e^{i \lambda_{q,k} (i_q - i_k)} f_j^{\nu_q, k} (\lambda_{q,k}) d\lambda_{q,k}$, we obtain that

$$\prod_{1 \leq i_1, \ldots, i_{2p} \leq n_j} \rho_j^{\nu_q, k} (i_q - i_k) = \int_{[-\pi, \pi]^{2(p-1)}} D_{n_j} \left( \sum_{k=2}^{2p} \lambda_{1,k} \right) D_{n_j} \left( -\lambda_{1,2} + \sum_{k=3}^{2p} \lambda_{2,k} \right)$$

$$\cdots D_{n_j} \left( -\lambda_{1,3} - \lambda_{2,3} + \sum_{k=4}^{2p} \lambda_{3,k} \right) \cdots D_{n_j} \left( -\sum_{q=1}^{\nu_q, 2p} \lambda_{q,2p} \right) \prod_{1 \leq q < k \leq 2p} f_j^{\nu_q, k} (\lambda_{q,k}) d\lambda_{q,k},$$

with the convention that $f_j^{0,0}(\lambda) d\lambda$ is a Dirac measure at 0. The number of $D_{n_j}$ in the previous product is equal to $2p$. Since the $\ell_i$’s are greater than 1, there are at least one $\lambda_{q,k}$ in each
Moreover, there exists at least one \( \mathcal{D}_{n_j} \) having a sum of at least two \( \lambda_{q,k} \)'s as argument otherwise there are \( p \) pairs of equal indices in the set \( \{ \ell_1, \ldots, \ell_{2p} \} \), which corresponds to the case previously addressed. To conclude the proof of (47), we use the same arguments as those used in the odd case.

If \(|\{i_1, \ldots, i_{2p}\}| < 2p\), the number of \( \mathcal{D}_{n_j} \) appearing in the r.h.s of (48) is equal to \(|\{i_1, \ldots, i_{2p}\}| \) and thus using the same arguments as previously, we can also conclude in this case that (47) holds.

We conclude the proof by applying Proposition 6.3.9. By (37), (48) and (49), Assumption (i) of Proposition 6.3.9 holds true. Assumption (ii) comes from \( \sum_{\tau = \ell \leq t} c_{\ell}^2 g_\infty^2(0)/\ell! \to \sum_{\ell > \ell} c_{\ell}^2 g_\infty^2(0)/\ell!, \) as \( t \) tends to infinity. Let us now check Assumption (iii). For this, it is enough to prove that \( \lim_{t \to \infty} \sup_{n_j \to \infty} \text{Var}(n_j^{-1/2} \sum_{i=1}^{n_j} \sum_{\ell > \ell} c_{\ell} H_{\ell}(X_{j,i})/\ell!) = 0 \). Note that \( \text{Var}(n_j^{-1/2} \sum_{i=1}^{n_j} \sum_{\ell > \ell} c_{\ell} H_{\ell}(X_{j,i})/\ell!) = \sum_{\ell > \ell} \sum_{|s| < n_j} c_{\ell}^2 (1 - |s|/n_j) \rho_j^2(s)/\ell! \). We aim at applying Lemma 12 to \( f_{n_j}, g_{n_j}, f \) and \( g \) defined hereafter. Let

\[
\begin{align*}
 f_{n_j}(\ell) &= \frac{c_{\ell}^2}{\ell!} \sum_{|s| < n_j} \left(1 - \frac{|s|}{n_j}\right) \rho_j^2(s), \\
 g_{n_j}(\ell) &= \frac{c_{\ell}^2}{\ell!} \sum_{|s| < n_j} \left(1 - \frac{|s|}{n_j}\right) \rho_j^2(s).
\end{align*}
\]

By Lemma 9 we get, as \( n_j \to \infty \), that

\[
 f_{n_j}(\ell) \to f(\ell) = 2\pi \frac{c_{\ell}^2}{\ell!} g_\infty^2(0) \quad \text{and} \quad g_{n_j}(\ell) \to g(\ell) = 2\pi \frac{c_{\ell}^2}{\ell!} g_\infty^2(0).
\]

Moreover, \( \sum_{\ell > \ell} g_{n_j}(\ell) \to 2\pi \sum_{\ell > \ell} c_{\ell}^2 g_\infty^2(0)/\ell! \) and Lemma 12 yields

\[
\lim_{n_j \to \infty} \frac{1}{n_j} \text{Var}(\sum_{i=1}^{n_j} \sum_{\ell > \ell} c_{\ell} H_{\ell}(X_{j,i})) = 2\pi \sum_{\ell > \ell} c_{\ell}^2 g_\infty^2(0),
\]

which tends to zero as \( t \) tends to infinity since \( \sum_{\ell} c_{\ell}^2 g_\infty^2(0)/\ell! \) is a convergent series.

\[\square\]

**Theorem 5.** Let \( \{X_{j,i}, \ j \geq 1, \ i \geq 0\} \) be an array of standard stationary Gaussian processes such that for a fixed \( j \geq 1 \), \( (X_{j,i})_{i \geq 0} \) has a spectral density \( f_j \) and an autocorrelation function \( \rho_j \) defined by \( \rho_j(k) = \mathbb{E}(X_{j,0}X_{j,k}), \) for all \( k \geq 0 \). Let \( F_j \) be the c.d.f of \( X_{j,1} \) and \( F_{n_j} \) the empirical c.d.f computed from \( X_{j,1}, \ldots, X_{j,n_j} \). If \( \{n_j\}_{j \geq 1} \) is a sequence of integers such that \( n_j \) tends to infinity as \( j \) tends to infinity and if Condition (55) holds then

\[
\sqrt{n_j}(F_{n_j} - F_j) \overset{d}{\to} W \quad \text{in} \quad D([-\infty, \infty]),
\]

(49)
as \( j \) tends to infinity, where \( D([-\infty, \infty]) \) denotes the Skorokhod space on \([-\infty, \infty]\) and \( W \) is a Gaussian process with covariance function

\[
\mathbb{E}[W(x)W(y)] = 2\pi \sum_{q \geq 1} \frac{J_q(x)J_q(y)}{q!} g^{(q)}_{\infty}(0), \quad x, y \in \mathbb{R},
\]

where \( J_q(x) = \mathbb{E}[H_q(X)\{1\{X \leq x\} - \mathbb{E}(1\{X \leq x\})\}] \), \( H_q \) is the \( q \)-th Hermite polynomial and \( X \) is a standard Gaussian random variable.

Proof of Theorem 5. Let \( S_j(x) = n_j^{-1/2} \sum_{i=1}^{n_j} \left( 1\{X_{j,i} \leq x\} - F_j(x) \right) \), for all \( x \) in \( \mathbb{R} \). We shall first prove that for \( x_1, \ldots, x_Q \) and \( a_1, \ldots, a_Q \) in \( \mathbb{R} \)

\[
\sum_{q=1}^Q a_q S_j(x_q) \xrightarrow{d} \mathcal{N}\left(0, 2\pi \sum_{i \geq 1} \frac{c_i^2}{i!} g^{(i)}_{\infty}(0)\right), \quad j \to \infty , \tag{50}
\]

where \( c_i \) is the \( i \)-th Hermite coefficient of the function \( h \) defined by

\[
h(\cdot) = \sum_{q=1}^Q a_q \left( 1\{x_q \} - \mathbb{E}(1\{x_q \}) \right). \]

Thus, \( \sum_{q=1}^Q a_q S_j(x_q) = n_j^{-1/2} \sum_{i=1}^{n_j} h(X_{j,i}) \), where \( h \) is bounded and of Hermite rank \( \tau \geq 1 \) since for all \( t \) in \( \mathbb{R} \), \( \mathbb{E}(X 1_{X \leq t}) = \int_{\mathbb{R}} x 1_{x \leq t} \phi(x) \, dx = \int_{-\infty}^{t} (-\varphi(x))' \, dx = -\varphi(t) \neq 0 \), and the CLT (50) follows from Theorem 4.

Let us now prove that there exists a positive constant \( C \) and \( \beta > 1 \) such that for all \( r \leq s \leq t \),

\[
\mathbb{E}\left(|S_j(s) - S_j(r)|^2 | S_j(t) - S_j(s)|^2 \right) \leq C |t - r|^\beta . \tag{51}
\]

The convergence (50) then follows from (50), (51) and Theorem 13.5. Note that

\[
\mathbb{E}\left(|S_j(s) - S_j(r)|^2 | S_j(t) - S_j(s)|^2 \right) = \frac{1}{n_j^2} \sum_{i,i'=1}^{n_j} \sum_{l,l'=1}^{n_j} \mathbb{E}\left( (k_s - k_r)(X_{j,i})(k_s - k_r)(X_{j,i'})(k_t - k_s)(X_{j,i})(k_t - k_s)(X_{j,i'}) \right),
\]

where \( k_t(X) = 1_{\{X \leq t\}} - \mathbb{E}(1_{\{X \leq t\}}) \). By expanding each difference of functions in Hermite polynomials, we get

\[
\mathbb{E}\left(|S_j(s) - S_j(r)|^2 | S_j(t) - S_j(s)|^2 \right) = \frac{1}{n_j^2} \sum_{i,i'=1}^{n_j} \sum_{l,l'=1}^{n_j} \sum_{p_1 \ldots p_4 \geq 1} c_{p_1}(k_s - k_r)c_{p_2}(k_s - k_r)c_{p_3}(k_t - k_s)c_{p_4}(k_t - k_s) \mathbb{E}\left( H_{p_1}(X_{j,i})H_{p_2}(X_{j,i'})H_{p_3}(X_{j,i})H_{p_4}(X_{j,i'}) \right).
\]
Using the same arguments as in the case where \( m \) is even in the proof of Theorem \( 4 \) we obtain

\[
\mathbb{E} \left( |S_j(s) - S_j(r)|^2 | S_j(t) - S_j(s) |^2 \right) = \frac{1}{n_j^2} \sum_{p_1,p_2 \geq 1} \sum_{i,i',l,l'} c_{p_1}(k_l - k_s) c_{p_2}(k_s - k_r) \rho_j^{p_1}(l - i) \rho_j^{p_2}(l' - i') \rho_j^{p_1}(l - i) \rho_j^{p_2}(l' - i') \\
+ c_{p_1}(k_l - k_s) c_{p_1}(k_s - k_r) c_{p_2}(k_l - k_s) c_{p_2}(k_s - k_r) \rho_j^{p_1}(l - i) \rho_j^{p_2}(l' - i') \rho_j^{p_1}(l - i) \rho_j^{p_2}(l' - i') + O(n_j^{-1}) .
\]

Let \( \| \cdot \|_2 = (\mathbb{E}(\cdot)^2)^{1/2} \) and \( \langle f, g \rangle = \mathbb{E}[f(X)g(X)] \), where \( X \) is a standard Gaussian random variable. Since, by \([64]\), \( \sum_{i,i',l,l'} \rho_j^{p_1}(l - i) \rho_j^{p_2}(l' - i') = O(n_j^2) \), we get with the Cauchy-Schwarz inequality that there exists a positive constant \( C \) such that

\[
\mathbb{E} \left( |S_j(s) - S_j(r)|^2 | S_j(t) - S_j(s) |^2 \right) \leq C \sum_{p_1,p_2 \geq 1} \left[ \frac{c_{p_1}(k_l - k_s) c_{p_2}(k_s - k_r)}{p_1! p_2!} + \frac{c_{p_1}(k_l - k_s) c_{p_1}(k_s - k_r) c_{p_2}(k_l - k_s) c_{p_2}(k_s - k_r)}{p_1! p_2!} \right] \leq C \left( \| k_l - k_s \|_2^2 \| k_s - k_r \|_2^2 + \| k_l - k_s, k_s - k_r \|_2^2 \right) \leq C \| k_l - k_s \|_2^2 \| k_s - k_r \|_2^2 .
\]

Note that \( \| k_l - k_s \|_2^2 \leq 2(\| \mathbb{1}_{\{X \leq t\}} - \mathbb{1}_{\{X \leq s\}} \|_2^2 + \| \mathbb{E}(\mathbb{1}_{\{X \leq s\}}) - \mathbb{E}(\mathbb{1}_{\{X \leq t\}}) \|_2^2 ) \). Since \( s \leq t \), \( \| \mathbb{1}_{\{X \leq t\}} - \mathbb{1}_{\{X \leq s\}} \|_2^2 = \Phi(t) - \Phi(s) \leq C |t - s| \), where \( \Phi \) denotes the c.d.f of a standard Gaussian random variable. Moreover, \( \| \mathbb{E}(\mathbb{1}_{\{X \leq s\}}) - \mathbb{E}(\mathbb{1}_{\{X \leq t\}}) \|_2^2 = \| \Phi(t) - \Phi(s) \|_2^2 \leq C |t - s|^2 \), which concludes the proof of \([51]\) with \( \beta = 2 \). \( \square \)

**Proof of Proposition \( 7 \)** For \( * = CL \), the proof of \([22]\) is immediate, since

\[
\sqrt{n_j} (\tilde{\sigma}_{CL,j} - \sigma_j^2) = \frac{1}{\sqrt{n_j}} \sum_{i=0}^{n_j-1} (W_{j,i}^2 - \sigma_j^2) = \frac{2\sigma_j^2}{\sqrt{n_j}} \sum_{i=0}^{n_j-1} \text{IF} \left( \frac{W_{j,i}}{\sigma_j}, \text{CL}, \Phi \right) .
\]

Let us now prove \([22]\) for \( * = MAD \). Let us denote by \( F_{n_j} \) the empirical c.d.f of \( W_{j,0:n_j-1} \) and by \( F_j \) the c.d.f of \( W_{j,0} \). Note that

\[
\tilde{\sigma}_{MAD,j} = m(\Phi) T_0 (F_{n_j}) ,
\]

where \( T_0 = T_2 \circ T_1 \) with \( T_1 : F \mapsto \{ r \mapsto \int_{\mathbb{R}} \mathbb{1}_{\{|x| \leq r\}} dF(x) \} \) and \( T_2 : U \mapsto U^{-1}(1/2) \). To prove \([22]\), we start by proving that \( \sqrt{n_j} (F_{n_j} - F_j) \) converges in distribution in the space of cadlag functions equipped with the topology of uniform convergence. This convergence follows by applying Theorem \( 5 \) to \( X_{j,i} = W_{j,i}/\sigma_j \) which is an array of zero mean stationary Gaussian processes by \([20]\, Corollary \,1\). The spectral density \( f_j \) of \( (X_{j,i})_{i \geq 0} \) is given by \( f_j(\lambda) = D_{j,0}(\lambda; f)/\sigma_j^2 \) where \( D_{j,0}(\cdot; f) \) is the within scale spectral density of the process \( \{W_{j,k}\}_{k \geq 0} \) defined in \([12]\) and \( \sigma_j^2 \) is the wavelet spectrum defined in \([14]\). Here, \( g_\infty(\lambda) = \)
\( D_{\infty,0}(\lambda; d)/K(d) \), with \( D_{\infty,0}(\cdot; d) \) defined in \[13\] and \( K(d) = \int_{-\infty}^{+\infty} |\xi|^{-2d}|\hat{\psi}(\xi)|^2 d\xi \) since by \[20\], (26) and (29) in Theorem 1:

\[
\left| \frac{D_{2,0}(\lambda; f)}{f^*(0)K(d)2^{2d}} - \frac{D_{\infty,0}(\lambda; d)}{K(d)} \right| \leq C L K(d)^{-1} 2^{-\beta j} \to 0, \quad \text{as} \quad j \to \infty,
\]

\[
\left| \frac{\sigma_j^2}{f^*(0)K(d)2^{2d}} - 1 \right| \leq C L 2^{-\beta j} \to 0, \quad \text{as} \quad j \to \infty.
\]

Note also that, by \[20\], Theorem 1, \( g_\infty(\lambda) \) is a continuous and 2\( \pi \)-periodic function on \((-\pi, \pi)\). Moreover, \( g_\infty(\lambda) \) is bounded on \((-\pi, \pi)\) by Lemma \[11\] and \[33\] holds with

\[
u_j = C_1 \frac{2^{-\beta j}}{\sigma_j^2/2^{2d}} \left( 2^{-\beta j} + C_2 \frac{\sigma_j^2}{2^{2d}} \right) \to 0, \quad \text{as} \quad j \to \infty,
\]

where \( C_1 \) and \( C_2 \) are positive constants. The asymptotic expansion \[22\] for \( \hat{\sigma}_{\text{MAD},j} \) can be deduced from the functional Delta method stated \( e.g. \) in \[32\], Theorem 20.8 and the classical Delta Method stated \( e.g. \) in \[32\], Theorem 3.1. To show this, we have to prove that \( T_0 = T_1 \circ T_2 \) is Hadamard differentiable and that the corresponding Hadamard differential is defined and continuous on the whole space of cadlag functions. We prove first the Hadamard differentiability of the functional \( T_1 \). Let \( (g_t) \) be a sequence of cadlag functions with bounded variations such that \( \|g_t - g\|_\infty \to 0 \), as \( t \to 0 \), where \( g \) is a cadlag function. For any non-negative \( r \), we consider

\[
\frac{T_1(F_j + t g_t)[r] - T_1(F_j)[r]}{t} = \frac{(F_j + t g_t)(r) - (F_j + t g_t)(-r) - F_j(r) + F_j(-r)}{t} = \frac{t g_t(r) - t g_t(-r)}{t} = g_t(r) - g_t(-r) \to g(r) - g(-r),
\]

since \( \|g_t - g\|_\infty \to 0 \), as \( t \to 0 \). The Hadamard differential of \( T_1 \) at \( g \) is given by:

\[
(DT_1(F_j), g)(r) = g(r) - g(-r).
\]

By \[32\], Lemma 21.3, \( T_2 \) is Hadamard differentiable. Finally, using the Chain rule \[32\], Theorem 20.9, we obtain the Hadamard differentiability of \( T_0 \) with the following Hadamard differential:

\[
DT_0(F_j).g = -\frac{(DT_1(F_j), g)(T_0(F_j))}{(T_1(F_j), T_0(F_j))} = -\frac{g(T_0(F_j)) - g(-T_0(F_j))}{(T_1(F_j), T_0(F_j))}.
\]

In view of the last expression, \( DT_0(F_j) \) is a continuous function of \( g \) and is defined on the whole space of cadlag functions. Thus by \[32\], Theorem 20.8, we obtain:

\[
m(\Phi)\sqrt{n_j} \left( T_0(F_n) - T_0(F_j) \right) = m(\Phi) DT_0(F_j) \left\{ \sqrt{n_j}(F_{n_j} - F_j) \right\} + o_P(1),
\]
where \( m(\Phi) \) is the constant defined in [20]. Since \( T_0(F_j) = \sigma_j/m(\Phi) \) and \( (T_1(F_j))' = 2\sigma_j^{-1}\varphi(r/\sigma_j) \), where \( \varphi \) is the p.d.f of a standard Gaussian random variable, we get

\[
\sqrt{n_j}(\hat{\sigma}_{\text{MAD},j} - \sigma_j) = \frac{\sigma_j}{\sqrt{n_j}} \sum_{i=0}^{n_j-1} \text{IF} \left( \frac{W_{j,i}}{\sigma_j}, \text{MAD}, \Phi \right) + o_P(1)
\]

and the expansion (22) for \( * = \text{MAD} \) follows from the classical Delta method applied with \( f(x) = x^2 \). We end the proof of Proposition 1 by proving the asymptotic expansion (22) for \( * = \text{CR} \). We use the same arguments as those used previously. In this case the Hadamard differentiability comes from [16, Lemma 1]. \( \square \)

The following theorem is an extension of [2, Theorem 4] to arrays of stationary Gaussian processes in the multidimensional case.

**Theorem 6.** Let \( X_{j,i} = \{ X_{j,i}^{(0)}, \ldots, X_{j,i}^{(d)} \} \) be an array of standard stationary Gaussian processes such that for \( j, j' \in \{ 0, \ldots, d \} \), the vector \( \{ X_{j,i}^{(j)}, X_{j,i}^{(j')} \} \) has a cross-spectral density \( f_{j,j'} \) and a cross-correlation function \( \rho_{j,j'} \) defined by \( \rho_{j,j'}(k) = \mathbb{E}(X_{j,i}^{(j)}X_{j,i+k}^{(j')}) \), for all \( k \geq 0 \). Assume also that there exists a non increasing sequence \( \{ u_J \} \) such that \( u_J \) tends to zero as \( J \) tends to infinity and for all \( J \geq 1 \),

\[
\sup_{\lambda \in (-\pi, \pi)} \left| f_{j,j'}^{(j,j')} (\lambda) - g_{j,j'}^{(j,j')} (\lambda) \right| \leq u_J ,
\]

where \( g_{j,j'}^{(j,j')} \) is a \( 2\pi \)-periodic function which is bounded on \( (-\pi, \pi) \) and continuous at the origin. Let \( h \) be a function on \( \mathbb{R} \) such that \( \mathbb{E}[h(X)^2] < \infty \), where \( X \) is a standard Gaussian random variable, and of Hermite rank \( \tau \geq 1 \). Let \( \beta = \{ \beta_0, \ldots, \beta_d \} \) in \( \mathbb{R}^{d+1} \) and \( \mathcal{H} : \mathbb{R}^{d+1} \rightarrow \mathbb{R} \) the real valued function defined by \( \mathcal{H}(x) = \sum_{j=0}^{d} \beta_j h(x_j) \). Let \( \{ n_J \} \) be a sequence of integers such that \( n_J \) tends to infinity as \( J \) tends to infinity. Then

\[
\frac{1}{\sqrt{n_J}} \sum_{i=1}^{n_J} \mathcal{H}(X_{j,i}) \xrightarrow{d} \mathcal{N}(0, \tilde{\sigma}^2) , \quad \text{as} \quad J \rightarrow \infty ,
\]

where

\[
\tilde{\sigma}^2 = \lim_{n \rightarrow \infty} \text{Var} \left( \frac{1}{\sqrt{n_J}} \sum_{i=1}^{n_J} \mathcal{H}(X_{j,i}) \right) = 2\pi \sum_{\ell \geq \tau} \frac{c^2}{\ell !} \sum_{0 \leq j,j' \leq d} \beta_j \beta_{j'} (g_{j,j'}^{(j,j')})^\ell (0).
\]

In the previous equality, \( c_\ell = \mathbb{E}[h(X)H_\ell(X)] \), where \( H_\ell \) is the \( \ell \)-th Hermite polynomial and \( X \) is a standard Gaussian random variable.

The proof of Theorem 6 follows the same lines as the one of Theorem 4 and is thus omitted.
Proof of Theorem 2. Without loss of generality, we set \( f^*(0) = 1 \). In order to prove (\ref{eq:26}), let us first prove that for \( \alpha = (\alpha_0, \ldots, \alpha_\ell) \) where the \( \alpha_i \)'s are in \( \mathbb{R} \),

\[
\sqrt{n^{2-\ell}2^{-\ell/2}d_j} \sum_{j=0}^{\ell} \alpha_j \left( \hat{\sigma}^2_{*j+1}(W_{j+1,0:n_{j+1}}) - \sigma^2_{*j+1} \right) \xrightarrow{d} N \left( 0, \alpha^T U_* (d) \alpha \right). \tag{54}
\]

By Proposition \ref{prop:1},

\[
\sqrt{n^{2-\ell}2^{-\ell/2}d_j} \sum_{j=0}^{\ell} \alpha_j \left( \hat{\sigma}^2_{*j+1}(W_{j+1,0:n_{j+1}}) - \sigma^2_{*j+1} \right) = \sum_{j=0}^{\ell} \sqrt{n^{2-\ell}2^{-\ell/2}d_j} \frac{2 \alpha_j}{n_{j+1}} \sum_{i=0}^{n_{j+1}-1} \text{IF} \left( \frac{W_{j+1,i}}{\sigma_{j+1}}, *, \Phi \right) + o_P(1). \tag{55}
\]

Thus, proving (\ref{eq:54}) amounts to proving that

\[
\frac{2^{-\ell/2}F^*(0)K(d)}{\sqrt{n^{2-\ell}2^{-\ell/2}d_j}} \sum_{j=0}^{\ell} 2 \alpha_j 2^{2d_j+1} = \sum_{j=0}^{\ell} \sum_{i=0}^{n_{j+1}-1} \text{IF} \left( \frac{W_{j+1,i}}{\sigma_{j+1}}, *, \Phi \right) \xrightarrow{d} N \left( 0, \alpha^T U_* (d) \alpha \right), \tag{56}
\]

since \( \sigma^2_{*j+1} \sqrt{n^{2-\ell}2^{-\ell/2}d_j}/n_{j+1} \sim 2^{2d_j-\ell/2+j}K(d)f^*(0)/\sqrt{n^{2-\ell}2^{-\ell/2}d_j} \), as \( n \) tends to infinity, by \cite{26}, (29) in Theorem 1. Note that

\[
\sum_{i=0}^{n_{j+1}-1} \text{IF} \left( \frac{W_{j+1,i}}{\sigma_{j+1}}, *, \Phi \right) = \sum_{i=0}^{n_{j+1}-1} \sum_{i=0}^{2^{d_j}-1} \text{IF} \left( \frac{W_{j+1,2^{d_j-i}+v}}{\sigma_{j+1}}, *, \Phi \right) + \sum_{q=n_{j+1}-(T-1)(2^{d_j}-1)}^{n_{j+1}-1} \text{IF} \left( \frac{W_{j+1,q}}{\sigma_{j+1}}, *, \Phi \right)
\]

Using the notation: \( \beta_j = 2 \alpha_j 2^{2d_j-\ell/2+j}K(d)f^*(0) \) and that IF is either bounded or equal to \( H_2/2 \),

\[
\frac{1}{\sqrt{n^{2-\ell}2^{-\ell/2}d_j}} \sum_{j=0}^{\ell} \beta_j \sum_{i=0}^{n_{j+1}-1} \text{IF} \left( \frac{W_{j+1,i}}{\sigma_{j+1}}, *, \Phi \right) = \frac{1}{\sqrt{n^{2-\ell}2^{-\ell/2}d_j}} \sum_{j=0}^{\ell} \beta_j \sum_{i=0}^{n_{j+1}-1} \sum_{v=0}^{2^{d_j}-1} \text{IF} \left( \frac{W_{j+1,2^{d_j-i}+v}}{\sigma_{j+1}}, *, \Phi \right) + o_P(1)
\]

\[
= \frac{1}{\sqrt{n^{2-\ell}2^{-\ell/2}d_j}} \sum_{i=0}^{n_{j+1}-1} \text{IF} \left( \frac{W_{j+1,i}}{\sigma_{j+1}}, *, \Phi \right) + o_P(1),
\]

where

\[
\text{IF} \left( \frac{W_{j+1,i}}{\sigma_{j+1}}, *, \Phi \right) = \sum_{j=0}^{\ell} \beta_j \sum_{v=0}^{2^{d_j-1}} \text{IF} \left( \frac{W_{j+1,2^{d_j-i}+v}}{\sigma_{j+1}}, *, \Phi \right)
\]
and

\[ Y_{\ell, i} = \begin{pmatrix} W_{J_0 + \ell, i} & W_{J_0 + \ell - 1, 2i} & \cdots & W_{J_0 + j, 2\ell - j - 1} \\ \sigma_{J_0 + \ell} & \sigma_{J_0 + \ell - 1} & \cdots & \sigma_{J_0 + j} \\ \vdots & \vdots & \ddots & \vdots \\ W_{J_0 + j, 2\ell - j - 1} & \cdots & W_{J_0, 2i} & W_{J_0, 2\ell - 1} \end{pmatrix}^T \]

is a \((2^\ell + 1) - 1\)-dimensional stationary Gaussian vector. By Lemma 7, \(F\) is of Hermite rank larger than 2. Hence, from Theorem 6 applied to \(H(\cdot) = F(\cdot), X_{\ell, i} = Y_{\ell, i}\) and \(h(\cdot) = IF(\cdot)\), we get

\[
\frac{1}{\sqrt{n_{J_0 + \ell}}} \sum_{i=0}^{n_{J_0 + \ell} - 1} F(Y_{\ell, i}, *, \Phi) \xrightarrow{d} N(0, \sigma^2) ,
\]

where \(\sigma^2 = \lim_{n \to \infty} n_{J_0 + \ell} \text{Var}\left( \sum_{i=0}^{n_{J_0 + \ell} - 1} F(Y_{\ell, i}, *, \Phi) \right)\). By [20, (26) and (29)] and by using the same arguments as those used in the proof of Proposition 1 Condition 52 of Theorem 6 holds with \(f_j^{(j')}(\lambda) = D_{j_0 + j, j'}^{(r)}(\lambda; f) / \sigma_{J_0 + j'}\) and \(g_{j_0 + j'}^{(j')} = D_{\infty, j_0 + j'}^{(r)}(\lambda; d) / K(d)\), where \(0 \leq r \leq 2^{j - j'} - 1\) and \(D_{j_0 + j, j'}^{(r)}(\cdot; f)\) is the cross-spectral density of the stationary between scale process defined in [12], Lemma 11 and [20, Theorem 1] ensure that \(D_{\infty, j_0 + j'}^{(r)}(\cdot; d)\) is a bounded, continuous and \(2\pi\)-periodic function.

By using Mehler’s formula [6, Eq. (2.1)] and the expansion of IF onto the Hermite polynomials basis given by: \(IF(x, *, \Phi) = \sum_{p \geq 2} c_p(\Phi) H_p(x) / p!\), where \(c_p(\Phi) = \mathbb{E}[IF(X, *, \Phi)H_p(X)]\), \(H_p\) being the \(p\)th Hermite polynomial, we get

\[
\frac{1}{n_{J_0 + \ell}} \text{Var}\left( \sum_{i=0}^{n_{J_0 + \ell} - 1} F(Y_{\ell, i}, *, \Phi) \right) = \frac{1}{n_{J_0 + \ell}} \sum_{j, j'}=1^\ell \sum_{i, i'=0}^{n_{J_0 + \ell} - 1} \sum_{0}^{2^{j - j'} - 1} \sum_{0}^{2^{j' - j} - 1} \mathbb{E}\left[ IF\left( \frac{W_{J_0 + j, 2^{j - j'} - i} + v', \sigma_{J_0 + j'} \right), *, \Phi \right] IF\left( \frac{W_{J_0 + j', 2^{j' - j} - i'} + v}{\sigma_{J_0 + j'}}, *, \Phi \right) \right] + o(1)
\]

\[
= \frac{1}{n_{J_0 + \ell}} \sum_{j, j'=1}^\ell \beta_j \beta_{j'} \sum_{0}^{n_{J_0 + \ell} - 1} \sum_{0}^{n_{J_0 + j' - 1}} \sum_{0}^{n_{J_0 + j} - 1} \mathbb{E}\left[ IF\left( \frac{W_{J_0 + j, i} + v}{\sigma_{J_0 + j'}}, *, \Phi \right) IF\left( \frac{W_{J_0 + j', i'} + v}{\sigma_{J_0 + j'}}, *, \Phi \right) \right] + o(1)
\]

\[
= \frac{1}{n_{J_0 + \ell}} \sum_{j, j'=1}^\ell \beta_j \beta_{j'} \sum_{0}^{n_{J_0 + j' - 1}} \sum_{0}^{n_{J_0 + j} - 1} \sum_{0}^{n_{J_0 + \ell} - 1} \sum_{0}^{2^{j - j'} - 1} \sum_{p \geq 2} \frac{c^2_p(\Phi)}{p!} \left( \mathbb{E}\left[ \frac{W_{J_0 + j, 2^{j - j'} - i} + v}{\sigma_{J_0 + j'}} \right] \right)^p + o(1) .
\]

Without loss of generality, we shall assume in the sequel that \(j \geq j'\). [58] can be rewritten as follows by using that \(i' = 2^{j' - j} q + r\), where \(q \in \mathbb{N}\) and \(r \in \{0, 1, \ldots, 2^{j' - j'} - 1\}\) and Eq. (18)
\[
\lim_{n \to \infty} \left( I_{\varphi_2} \right) = \left( \frac{1}{\sqrt{n}} \right) \left( \frac{1}{\sqrt{n}} \right) = \left( \frac{1}{\sqrt{n}} \right) \left( \frac{1}{\sqrt{n}} \right) = \left( \frac{1}{\sqrt{n}} \right) \left( \frac{1}{\sqrt{n}} \right)
\]

where \( D_{\varphi_2} \) is the cross-spectral density of the stationary between scale process defined in [12]. We aim at applying Lemma [12] with \( f_n, g_n, f \) and \( g \) defined hereafter.

\[
f_{n,j_0+j}(\tau, p) = \frac{c_p^2(\varphi_4)}{p!} \sum_{\tau=0}^{2^{j_0+j}-1} 1 \{|\tau| < n,j_0+j\} \left( 1 - \frac{|\tau|}{n,j_0+j} \right) \left( \frac{D_{\varphi_2}(\tau)}{\sigma_{\varphi_2}} \right)^p.
\]

Observe that \( |f_{n,j_0+j}| \leq g_{n,j_0+j} \), where

\[
g_{n,j_0+j}(\tau, p) = \frac{c_p^2(\varphi_4)}{p!} \sum_{\tau=0}^{2^{j_0+j}-1} 1 \{|\tau| < n,j_0+j\} \left( 1 - \frac{|\tau|}{n,j_0+j} \right) \left( \frac{D_{\varphi_2}(\tau)}{\sigma_{\varphi_2}} \right)^2.
\]

Using [20, (26) and (29) in Theorem 1] we get that

\[
\lim_{n \to \infty} \frac{D_{\varphi_2}(\tau)}{\sigma_{\varphi_2}} = \frac{2^{d(j_0+j)}}{K(d)} D_{\varphi_2}(\tau).
\]

This implies that \( \lim_{n \to \infty} f_{n,j_0+j}(\tau, p) = f(\tau, p) \) where

\[
f(\tau, p) = \frac{c_p^2(\varphi_4)}{p!} \sum_{\tau=0}^{2^{j_0+j}-1} \left( \frac{2^{d(j_0+j)}}{K(d)} \right)^p D_{\varphi_2}(\tau) e^{i\lambda\tau} d\lambda.
\]

Furthermore, \( \lim_{n \to \infty} g_{n,j_0+j}(\tau, p) = g(\tau, p) \) where

\[
g(\tau, p) = \frac{c_p^2(\varphi_4)}{p!} \frac{2^{d(j_0+j)}}{K(d)^2} \left| \int_{-\pi}^{\pi} D_{\varphi_2}(\tau) e^{i\lambda\tau} d\lambda \right|^2.
\]

and \( |x|^2 = \sum_{k=1}^{r} x_k^2 \) for \( x = (x_1, \ldots, x_r) \in \mathbb{R}^r \). Using (63)-(65) in [20] we get

\[
\sum_{\tau \in \mathbb{Z}} \sum_{p \geq 2} g_{n,j_0+j}(\tau, p) \to \left( \sum_{p \geq 2} \frac{c_p^2(\varphi_4)}{p!} \frac{2^{d(j_0+j)}}{K(d)^2} \right)^2 \left| \int_{-\pi}^{\pi} D_{\varphi_2}(\tau) e^{i\lambda\tau} d\lambda \right|^2, \quad \text{as } n \to \infty.
\]
Then, with Lemma 12, we obtain

$$\tilde{\sigma}^2 = \sum_{p \geq 2} \frac{c^2_p(f^*(0))^2}{p!K(d)^{p-2}} \sum_{j, j' = 0}^\ell 4\alpha_j \alpha_{j'} 2^{dj(2+p)} 2^{dj'(2-p)+j'} \sum_{\tau \in \mathbb{Z}} \sum_{r=0}^{2j-j'-1} \left( \int_{-\pi}^\pi D_{\infty,j-j'}^{(r)}(\lambda; d)e^{i\lambda \tau} d\lambda \right)^{p}.$$ 

\[ \square \]

7. Technical Lemmas

**Lemma 7.** Let $X$ be a standard Gaussian random variable. The influence functions $IF$ defined in Proposition 1 have the following properties

$$E[IF(X, *, \Phi)] = 0,$$  \hspace{1cm} (59)

$$E[XIF(X, *, \Phi)] = 0,$$  \hspace{1cm} (60)

$$E[X^2IF(X, *, \Phi)] \neq 0.$$  \hspace{1cm} (61)

**Proof of Lemma 7.** We only have to prove the result for $* = \text{MAD}$ since the result for $* = \text{CR}$ follows from [16, Lemma 12]. (59) comes from $E(\mathbb{I}_{\{X \leq \Phi^{-1}(3/4)\}}) = 3/4$ and $E(\mathbb{I}_{\{X \leq -\Phi^{-1}(3/4)\}}) = 1/4$, where $X$ is a standard Gaussian random variable. (60) follows from

$$\int_{\mathbb{R}} x^2 \mathbb{I}_{\{x \leq -\Phi^{-1}(3/4)\}} \varphi(x) dx - \int_{\mathbb{R}} x^2 \mathbb{I}_{\{x \leq \Phi^{-1}(3/4)\}} \varphi(x) dx = -\varphi(\Phi^{-1}(3/4)) + \varphi(-\Phi^{-1}(3/4)) = 0,$$

where $\varphi$ is the p.d.f. of a standard Gaussian random variable and the fact that $E(X) = 0$. Let us now compute $E[X^2IF(X, \text{MAD}, \Phi)]$. Integrating by parts, we get

$$\int_{\mathbb{R}} x^2 \mathbb{I}_{\{x \leq -\Phi^{-1}(3/4)\}} \varphi(x) dx - 3/4 - \int_{\mathbb{R}} x^2 \mathbb{I}_{\{x \leq -\Phi^{-1}(3/4)\}} \varphi(x) dx + 1/4 = -2\varphi(\Phi^{-1}(3/4)).$$

Thus, $E[X^2IF(X, \text{MAD}, \Phi)] = 2 \neq 0$, which concludes the proof. \[ \square \]

**Lemma 8.** Let $X$ be a standard Gaussian random variable. The influence functions $IF$ defined in Lemma 1 have the following properties

$$E[IF^2(X, \text{MAD}, \Phi)] = \frac{m^2(\Phi)}{16\varphi(\Phi^{-1}(3/4))^2} = 1.3601,$$  \hspace{1cm} (62)

$$E[IF^2(X, \text{CR}, \Phi)] \approx 0.6077.$$  \hspace{1cm} (63)

**Proof of Lemma 8.** Eq (63) comes from [27]. Since

$$E[IF^2(X, \text{MAD}, \Phi)] = \frac{m^2(\Phi)}{4\varphi(\Phi^{-1}(3/4))^2} \text{Var} (\mathbb{I}_{\{|X| \leq \Phi^{-1}(3/4)\}}),$$

where $\mathbb{I}_{\{|X| \leq \Phi^{-1}(3/4)\}}$ is a Bernoulli random variable with parameter $1/2$, (62) follows. \[ \square \]
Lemma 9. Under the assumptions of Theorem \[4\] and for any fixed \( \ell \geq 1 \),

\[
\frac{1}{n_j} \sum_{r,s=1}^{n_j} \rho_j^r(r-s) \to 2\pi g_\infty^r(0), \text{ as } n_j \to \infty. \tag{64}
\]

Proof of Lemma 9. Let us first prove that

\[
\frac{1}{n_j} \sum_{1 \leq r,s \leq n_j} \rho_j(r-s) \to 2\pi g_\infty(0), \text{ as } n_j \to \infty. \tag{65}
\]

Using that \( \mathcal{F}_{n_j} \) defined by \( \mathcal{F}_{n_j}(\lambda) = n_j^{-1} \sum_{r=1}^{n_j} e^{i\lambda r^2} \), for all \( \lambda \in [-\pi, \pi] \) satisfies \( \int_{-\pi}^{\pi} \mathcal{F}_{n_j}(\lambda) d\lambda = 2\pi \), we obtain

\[
\frac{1}{n_j} \left( \sum_{1 \leq r,s \leq n_j} \rho_j(r-s) \right) - 2\pi g_\infty(0) = \int_{-\pi}^{\pi} (f_j(\lambda) - g_\infty(\lambda)) \mathcal{F}_{n_j}(\lambda) d\lambda + \int_{-\pi}^{\pi} (g_\infty(\lambda) - g_\infty(0)) \mathcal{F}_{n_j}(\lambda) d\lambda. \tag{66}
\]

Using that \( \mathcal{F}_{n_j} \) is non-negative, \( \int_{-\pi}^{\pi} \mathcal{F}_{n_j}(\lambda) d\lambda = 2\pi \) and \( \tag{65} \), the first term in the r.h.s of \( \tag{66} \) tends to zero as \( j \) tends to infinity. The second term in the r.h.s of \( \tag{66} \) can be bounded above as follows. For \( 0 < \eta \leq \pi \),

\[
\left| \int_{-\pi}^{\pi} (g_\infty(\lambda) - g_\infty(0)) \mathcal{F}_{n_j}(\lambda) d\lambda \right| \leq \int_{-\pi}^{-\eta} |g_\infty(\lambda) - g_\infty(0)| \mathcal{F}_{n_j}(\lambda) d\lambda + \int_{-\eta}^{\eta} |g_\infty(\lambda) - g_\infty(0)| \mathcal{F}_{n_j}(\lambda) d\lambda + \int_{\eta}^{\pi} |g_\infty(\lambda) - g_\infty(0)| \mathcal{F}_{n_j}(\lambda) d\lambda. \tag{67}
\]

Since there exists a positive constant \( C \) such that \( \mathcal{F}_{n_j}(\lambda) \leq C/(n_j|\lambda|^2) \), for all \( \lambda \in [-\pi, \pi] \), the first and last terms in the r.h.s of \( \tag{67} \) are bounded by \( C\pi/(n_j\eta^2) \). The continuity of \( g_\infty \) at 0 and the fact that \( \int_{-\eta}^{\eta} \mathcal{F}_{n_j}(\lambda) d\lambda = 2\pi \) ensure that the r.h.s of \( \tag{67} \) tends to zero as \( j \) tends to infinity. This concludes the proof of \( \tag{65} \).

Observe that for all \( k \in \mathbb{Z} \), \( \rho_j^r(k) = \int_{-\pi}^{\pi} e^{i\lambda k} f_j^e(\lambda) d\lambda \), where \( f_j^e \) is the \( \ell \)-th self-convolution of \( f_j \). Since \( \tag{65} \) implies that \( \sup_{\lambda \in (-\pi, \pi)} |f_j^e(\lambda) - g_\infty^e(\lambda)| \) tends to zero as \( j \) tends to infinity for any fixed \( \ell \geq 2 \), the same arguments as those used to prove \( \tag{65} \) lead to \( \tag{64} \). \( \square \)

Lemma 10. Under the assumptions of Theorem \[4\] let \( D_{n_j} \) and \( \mathcal{F}_{n_j} \) be defined by \( D_{n_j}(\lambda) = \sum_{r=1}^{n_j} e^{i\lambda r} \) and \( \mathcal{F}_{n_j}(\lambda) = n_j^{-1} \sum_{r=1}^{n_j} e^{i\lambda r^2} \), respectively, for all \( \lambda \in [-\pi, \pi] \). Then, the following two statements hold true.

(i) For any fixed \( j, \ell \geq 1 \),

\[
\| \mathcal{F}_{n_j} \ast f_j^e \|_\infty \leq 2\pi \left( \| f_j^e \|_\infty + g_\infty^e \|_\infty \right), \tag{68}
\]

where \( \| \mathcal{F}_{n_j} \ast f_j^e \|_\infty = \sup_{t \in \mathbb{R}} | \int_{-\pi}^{\pi} \mathcal{F}_{n_j}(t-\lambda) f_j^e(\lambda) d\lambda | \).
(ii) For any fixed $\ell \geq 1$,
\[
\sup_{x \in \mathbb{R}} \int_{-\pi}^{\pi} \frac{|D_{n_j}(\lambda + x)|}{\sqrt{n_j}} f_j^e(\lambda) d\lambda \to 0, \text{ as } n_j \to \infty. \tag{69}
\]

Proof of Lemma 10. (i) Using that $F_{n_j}$ is non-negative and such that $\int_{-\pi}^{\pi} F_{n_j}(\lambda) d\lambda = 2\pi$, we get that $\|F_{n_j} \ast f_j^e\|_{\infty} \leq 2\pi \|f_j^e\|_{\infty}$ and thus (68) follows from the triangle inequality.

(ii) Writing $f_j^e(\lambda) = (f_j^e(\lambda) - g_\infty^e(\lambda)) + g_\infty^e(\lambda)$ and using the Cauchy-Schwarz inequality, we get that for all $n_j$ tends to infinity. Since $F_{n_j}$ is a $2\pi$-periodic function, $\int_{-\pi}^{\pi} F_{n_j}(\lambda + x) d\lambda = 2\pi$ for all $x$ in $\mathbb{R}$ and thus the first term in the r.h.s of (70) tends to zero as $n_j$ tends to infinity.

Let us now study the second term in the r.h.s of (70). Since $D_{n_j}$ and $g_\infty$ are $2\pi$-periodic functions, $n_j^{-1/2} \int_{-\pi}^{\pi} |D_{n_j}(\lambda + x)| g_\infty^e(\lambda) d\lambda$ for all $x$ in $\mathbb{R}$. Then, by splitting the interval $[-\pi, \pi]$ into $[-\delta, \delta]$ and $[-\pi, \pi] \setminus [-\delta, \delta]$ and by using the Cauchy-Schwarz inequality, we get that for all $x$ in $\mathbb{R}$,
\[
\int_{-\pi}^{\pi} \frac{|D_{n_j}(\lambda + x)|}{\sqrt{n_j}} g_\infty^e(\lambda) d\lambda \leq \left( \int_{-\delta}^{\delta} F_{n_j}(u) du \right)^{1/2} \left( \int_{-\delta}^{\delta} (g_\infty^e(u - x)^2 du \right)^{1/2} + \left( \int_{[-\pi, \pi] \setminus [-\delta, \delta]} F_{n_j}(u) du \right)^{1/2} \left( \int_{[-\pi, \pi] \setminus [-\delta, \delta]} g_\infty^e(u - x)^2 du \right)^{1/2}.
\]

Using that $\int_{-\delta}^{\delta} F_{n_j}(u) du$ and $\int_{[-\pi, \pi] \setminus [-\delta, \delta]} F_{n_j}(u) du$ are bounded above by $\int_{[-\pi, \pi]} F_{n_j}(u) du = 2\pi$ and that $g_\infty$ is bounded, we get that there exists a positive constant $C(\ell)$ depending on $\ell$ such that
\[
\sup_{x \in \mathbb{R}} \int_{-\pi}^{\pi} \frac{|D_{n_j}(\lambda + x)|}{\sqrt{n_j}} g_\infty^e(\lambda) d\lambda \leq C(\ell) \|g_\infty\|_{\infty} \left( \sqrt{\delta} + \frac{1}{\sqrt{n_j}} \right).
\]

Setting $\delta = \delta_{n_j} = n_j^{\alpha - 1/2}$, with $\alpha$ in $(0, 1/2)$, (69) follows.

\[\square\]

Lemma 11. Let $e_u(\xi) = 2^{-u/2}[1, e^{-i2^{-u}\xi}, \ldots, e^{-i(2^{n-1})^{-2} - u}\xi]^T$, where $\xi \in \mathbb{R}$. For all $u \geq 0$, each component of the vector
\[
D_{\infty,u}(\lambda; d) = \sum_{l \in \mathbb{Z}} |\lambda + 2l|^{-2d} e_u(\lambda + 2l) \widehat{\psi}(\lambda + 2l) \hat{\psi}(2^{-u}(\lambda + 2l\pi)),
\]
is bounded on $(-\pi, \pi)$, where $\hat{\psi}$ is defined in $[4]$. 

Proof of Lemma 12. We start with the case where \( l = 0 \). Using (5), we obtain that
\[
2^{-u/2} |\lambda|^{-2d} |\hat{\psi}(2^{-u}\lambda)| = O(|\lambda|^{2M-2d}), \quad \text{as} \quad \lambda \to 0 \quad \text{hence}, 
\]
\[
2^{-u/2} |\lambda|^{-2d} |\hat{\psi}(2^{-u}\lambda)| = O(1). \quad \text{Let} \quad \mathbf{e}_u^{(k)} \quad \text{denotes} \quad \text{the} \quad k\text{-th} \quad \text{component} \quad \text{of} \quad \text{the} \quad \text{vector} \quad \mathbf{e}_u. 
\]
For \( l \neq 0 \), \( (\Omega, \mathcal{F}, \mu) \) ensures that for all \( \lambda \) in \((-\pi, \pi)\) there exists a positive constant \( C \) such that
\[
|\hat{\psi}(\lambda)| \leq C/(1 + |\lambda|)^{\alpha}. \quad \text{Then, there exists a positive constant} \quad C' \quad \text{such that}
\]
\[
\sum_{l \in \mathbb{Z}^*} |\lambda + 2\pi l|^{-2d} |\hat{\psi}(\lambda + 2\pi l)| |\hat{\psi}(2^{-u}(\lambda + 2\pi l))| \mathbf{e}_{u}^{(k)}(\lambda) \leq C' \sum_{l \in \mathbb{Z}^*} |\lambda + 2\pi l|^{-2d-2\alpha}. 
\]
If \( \lambda = 0 \), \( \sum_{l \in \mathbb{Z}^*} 1/|2\pi l|^{2d+2\alpha} < \infty \) by (14). If \( \lambda \neq 0 \), then, since \(-\pi \leq \lambda \leq \pi\), \( \sum_{l \in \mathbb{Z}^*} 1/|\lambda + 2\pi l|^{2d+2\alpha} \leq \sum_{l \in \mathbb{Z}^*} 1/|\pi(2l - 1)|^{2d+2\alpha} < \infty \) by (14).

Lemma 12. Let \( f_n \) and \( g_n \) be two sequences of measurable functions on a measure space \((\Omega, \mathcal{F}, \mu)\) such that for all \( n \), \( |f_n| \leq g_n \). Assume that \( \lim_{n \to \infty} g_n = g \), \( \lim_{n \to \infty} \int g_n \, d\mu = \int g \, d\mu \) and that \( \lim_{n \to \infty} f_n = f \). Then \( \int \lim_{n \to \infty} f_n \, d\mu = \lim_{n \to \infty} \int f_n \, d\mu \).

Proof of Lemma 12. Since \( |f_n| \leq g_n \), we have \(-g_n \leq f_n \leq g_n \). By applying Fatou’s Lemma first to \( g_n - f_n \) and after to \( f_n + g_n \), we get \( \lim \inf_{n \to \infty} \int (g_n - f_n) \geq \int g - \int f \) and \( \lim \inf_{n \to \infty} \int (g_n + f_n) \geq \int g + \int f \). Since \( \lim \inf_{n \to \infty} \int g_n = \int g \), \( \lim \inf_{n \to \infty} \int (g_n - f_n) \leq \int g + \lim \inf_{n \to \infty} (- \int f_n) \) and thus we deduce from the first inequality that \( \lim \sup_{n \to \infty} \int f_n \leq \int f \). In the same way, we deduce from the second inequality that \( \int f \leq \lim \inf_{n \to \infty} \int f_n \), which concludes the proof.
