Abstract—The effects of aspirin and treatment with geranylgeranylacetone (GGA), an antiulcer drug, on the content of gastric glycoproteins were investigated in pylorus-ligated rats. In normal rats, the amount of gastric glycoproteins in the mucous layer was about 1.5 times higher than that in the gastric mucosa, indicating that the glycoproteins were distributed in the mucous layer as a highly concentrated state. Aspirin (100 mg/kg, p.o.) decreased the content of gastric glycoproteins both in the mucous layer and in the gastric mucosa. The amount of the macromolecular fraction in the gastric juice, which corresponded to the gastric glycoproteins on the basis of molecular size, was not affected by aspirin. GGA (300 mg/kg, i.d.) could prevent the decreases of the total amount of gastric glycoproteins in the mucous layer plus gastric mucosa. These results indicated that the glycoproteins coating the surface of the gastric mucosa may play a role as a defensive mechanism and that GGA exerted an antiulcer effect on aspirin-induced mucosal damage through preventing the decreases in gastric glycoproteins.

The present study was undertaken to investigate the changes in gastric glycoproteins in the mucous layer and the gastric mucosa and in the gastric juice induced by aspirin. Additionally, the effect of geranylgeranylacetone (GGA), which had an antiulcer potency against aspirin-induced lesions (4), on the changes of the glycoproteins was examined.

Materials and Methods
Male Sprague-Dawley rats, weighing about 170 g, were used in these experiments. Animals were housed in a room maintained at a temperature of 22±2°C and at a humidity of 55±5%. They were deprived of food for 24 hr before the experiments, but had free...
Geranylgeranylacetone (all-trans-geranylgeranylacetone: 5-cis, 9-trans, 13-trans-geranylgeranylacetone=6:4; GGA) was synthesized at the Eisai Co., Ltd. and emulsified in 5% gum arabic and 0.6% Tween 80.

Aspirin ulcer in pylorus-ligated rats: According to the method of Okabe et al. (5), the pylorus of each animal was ligated under light ether anesthesia. Immediately after the ligation, aspirin was administered orally at a dose of 100 mg/kg, and the test drug was given intraduodenally at a dose of 300 mg/kg. Seven hr after the ligation, the animals were sacrificed under ether anesthesia. The stomach was removed, and the gastric juice was collected.

Analysis of the gastric glycoproteins by gel filtration: The amount of gastric glycoproteins in the mucous layer and the gastric mucosa were determined as previously reported (6) with gel filtration method (3). The stomach was incised along the greater curvature after removing the forestomach. From one half of the stomach, the mucous layer was scraped off with gauze, and the other half was left untreated. After lyophilizing, each stomach half was homogenized in 6 ml of 2% Triton X-100/50 mM Tris-HCl, pH 7.2, with an Ultra Turax (Janke Kunkel KG, Type TP 18/10 S2) and centrifuged at 10,000 rpm for 30 min. One ml of the supernatant was applied on a column of Bio-Gel A 1.5m (100-200 mesh, Biorad Laboratories, 1 x 35 cm), which had been equilibrated with the same buffer, and eluted at room temperature. Fractions of 1 ml were collected (Toyo, SF 160K), and aliquots were taken for the measurement of hexose by the phenol-sulfuric acid method (7) and protein by the method of Wang and Smith (8). Hexosamine was determined in pooled fractions according to the method of Neuhaus and Letzring (9).

The content of the glycoproteins in the mucous layer and gastric mucosa were determined as follows:

```
Stomach
   ↓ cutting off the forestomach
   ↓ dividing into two parts
   ↓ Wet wt. I   ↓ Wet wt. II
   ↓ lyophilizing   ↓ lyophilizing
   ↓ Dry wt. III   ↓ Dry wt. IV
   ↓ homogenizing   ↓ homogenizing
   ↓ centrifuged at 10,000 rpm for 30 min
   ↓ Sup.
   ↓ Bio-Gel A 1.5 m column chromatography
   ↓ Glycoproteins V   ↓ Glycoproteins VI
```

The content of the gastric glycoproteins was expressed as mg of hexose per mg of dry tissue (concentration) and μg of hexose per one stomach (total amount).

Concentration of Glycoproteins (mg/mg dry tissue) = V/III
Total amount of Glycoproteins (μg/stomach*) = V/(I+II)/I—(a)
(μg/gastric mucosa*) = V/(I+II)/II—(b)
(μg/mucous layer*) = (a) — (b)

*Total glycoproteins in the stomach = glycoproteins in the gastric mucosa plus mucous layer.

Collected gastric juice was centrifuged at 10,000 rpm for 30 min, and 1 ml of the supernatant was applied on a column of Bio-Gel A 1.5 m. The eluted fractions were analyzed for hexose and protein as described above.

Histochemical study of the stomach: The stomach opened along the greater curvature
was fixed in 95% ethanol and embedded in paraffin. Four μm paraffin sections were prepared and stained with periodic-acid-Schiff (PAS).

The Student’s t-test was used for statistical analysis.

Results

Changes in PAS positive substances in the stomach: As shown in Fig. 1, PAS positive substances were distributed in the superficial mucous layer and in the neck of the gland of the gastric mucosa. These substances in both layers were reduced after administration of aspirin at a dose of 100 mg/kg to pylorus-ligated rats. In aspirin plus GGA (300 mg/kg) treated animals, PAS positive substances were maintained at the normal level.

Effect of aspirin and treatment of GGA on the gastric glycoproteins: As shown in Fig. 2, the elution pattern of the extract of normal stomach showed three peaks of hexose (F-1, F-2 and F-3) which contained a protein component. Particularly in F-1, the peak of hexose and protein was found in the same position at the void volume. Hexose contents and hexosamine contents in F-1, F-2 and F-3 were 23%, 25%, 52% and 64%, 21%, 15%, respectively (Fig. 3). The nonretarded fraction (F-1) with an elution position coinciding with that of protein, containing a high percentage of hexosamine, was designated as "gastric glycoproteins" in this paper.

Figure 4 showed the characteristic column elution profiles of the stomach of the normal rat, aspirin treated rat (Control), and aspirin plus GGA treated rat. The peak designated as gastric glycoproteins (F-1) was significantly reduced by aspirin, while the other two peaks of lower molecular weight fractions (F-2, F-3) were not changed. In the aspirin plus GGA treated rat, the elution profile of the stomach was similar to that of the normal rat. The changes in hexose contents in F-1, F-2 and F-3 fractions of the stomach are summarized in Table 1; F-1, F-2 and F-3 fractions from the Bio-Gel A 1.5 m column were pooled as shown in Fig. 4, and hexose content in each fraction was determined. In the normal rat, the hexose contents in F-1, F-2 and F-3 were 9.22±0.15, 7.60±0.50,

12.22±0.88 mg/mg of dry tissue, respectively. Oral administration of aspirin at 100 mg/kg to pylorus-ligated rats, which produced severe mucosal damage in the glandular portion, caused 18% decreases in the concentration of gastric glycoproteins (F-1), significantly, but did not affect the lower molecular fractions (F-2, F-3). In aspirin plus GGA treated rats, the decreases in gastric glycoproteins (F-1) were 7% of the normal level. These results suggest that GGA prevented the decreases in gastric glycoproteins (F-1) contents induced by aspirin.

The changes in the gastric glycoproteins (F-1) were investigated by separating the stomach into the "mucous layer" and the
"gastric mucosa". In normal rats, total amounts of the gastric glycoproteins (F-1) in the mucous layer, the gastric mucosa, and in the mucous layer plus gastric mucosa were 822±38, 535±33 and 1360±35 μg, respectively (Fig. 5), and the concentrations of gastric glycoproteins (F-1) in each layer were 22.1±0.6, 4.9±0.3 and 9.2±0.2 mg/mg of dry tissue, respectively. Comparison of the content of gastric glycoproteins (F-1) in the mucous layer with that in the gastric mucosa indicated that the gastric glycoproteins (F-1) were distributed mainly in the mucous layer. As shown in Fig. 5, seven hr after the administration of aspirin, the amounts of gastric glycoproteins (F-1) in the mucous layer and gastric mucosa were significantly decreased by 23% and 32%, respectively. In aspirin plus GGA treated rats, the decreases in the glycoproteins (F-1) in each layer were 9% and 13%, respectively. The decreases in total gastric glycoproteins (F-1) in the mucous layer plus gastric mucosa were significantly prevented by GGA.

On the other hand, the lower molecular fractions (F-2, F-3) were predominantly distributed in the gastric mucosa (80%, 85% of the total amount, respectively) and were not affected by aspirin and GGA (data not shown).
Effect of aspirin and GGA on the Bio-Gel A 1.5 m column fractions of gastric juice:
The gastric juice collected from Shay rats was separated into two size classes on the basis of hexose content by Bio-Gel A 1.5 m column filtration (Fig. 6A). The larger

Discussion

The present study indicated that the gastric macromolecular glycoproteins were contained in the superficial mucous layer as a highly concentrated state and that the glycoprotein contents were decreased in the mucous layer and gastric mucosa following oral administration of aspirin. GGA, which had been shown to prevent aspirin-induced ulceration (4), could inhibit the decreases in the amount of gastric glycoproteins in the mucous layer and gastric mucosa. These findings were well associated with the changes in PAS positive substances in both layers as examined by the histochemical method. Based on these results, we hypothesized that the gastric macromolecular glycoproteins, which are the mucin type (3), play a role as a defensive mechanism, forming the mucous layer on the surface of the gastric mucosa. Allen et al. (10) have reported that the macromolecular glycoproteins in the human gastric mucosa were dissociated into four subunits by pepsin digestion, and they also discussed the
It is unlikely that the decreases in the gastric glycoprotein contents by aspirin are only a result of the mucosal damages since Azuumi et al. (3) demonstrated that the changes in contents of the glycoproteins were detected before the macroscopical changes of the mucosa. The inhibitory effect of aspirin on mucus biosynthesis (1, 2, 11) or mucus secretion (12) may cause the decreases in the gastric glycoproteins.

Mucus secretion in the gastric juice was also examined by using the same method of gel filtration. The content of the macromolecular fraction in the gastric juice, which had no detectable protein component, was not affected by aspirin, while that of the lower molecular fraction in the gastric juice was significantly increased when compared to the normal level. GGA had no significant effect on this change. It is not clear whether these fractions in the gastric juice are the component of gastric glycoproteins actively released or the degraded materials of gastric glycoproteins by pepsin digestion. Further investigation is necessary to clarify the significance of these changes in the gastric juice.

As previously reported (4), GGA showed a preventive effect on acid-back diffusion induced by aspirin; GGA inhibited the reduction of H+ ion concentration and the increment of Na+ ion concentration in the gastric juice induced by aspirin. These results suggest the possibility of a correlation between acid-back diffusion and the decreases in gastric glycoproteins in the stomach.

The preventive effect of GGA on the decreases in gastric glycoproteins may be attributed to action on the glycoprotein biosynthesis in the gastric mucosa since it was suggested that GGA might be involved in the glycoprotein synthesis through the enhancement of glycolipid biosynthesis in rat liver microsomes (13).

We have previously shown that GGA could inhibit the decreases in hexosamine content in the stomach induced by aspirin (4) or cold-restraint stress (14). Although hexosamine is contained not only in mucus glycoproteins but also in connective tissues, it was indicated from the present study that the greater part of the hexosamine content in the stomach extract was derived from the gastric macromolecular glycoproteins and that hexosamine content in the cell debris and/or connective tissue was negligible to the total content of hexosamine. These results indicated that GGA might also have a preventive effect on the reduction in gastric glycoproteins by stress and that hexosamine content in the stomach can serve as an indicator of the content of gastric glycoproteins.

In conclusion, the disturbance of biosynthesis of the gastric macromolecular glycoproteins may contribute to ulceration by aspirin. GGA showed a preventive effect on the reduction of gastric glycoproteins.
