 ENTROPY RIGIDITY FOR 3D ANOSOV/BILLIARD FLOWS

JACOPO DE SIMOI, MARTIN LEGUIL*, KURT VINHAGE, AND YUN YANG

Abstract. Given an integer $k \geq 5$, and a $C^k$ Anosov flow $\Phi$ on some compact connected 3-manifold preserving a smooth volume, we show that the measure of maximal entropy (MME) is the volume measure if and only if $\Phi$ is $C^{k-\varepsilon}$-conjugate to an algebraic flow, for $\varepsilon > 0$ arbitrarily small. Moreover, in the case of dispersing billiards, we show that if the measure of maximal entropy is equal to the volume measure, then the Birkhoff Normal Form of regular periodic orbits with a homoclinic intersection is linear.

1. Introduction

Anosov flows and Anosov diffeomorphisms are among the most well-understood dynamical systems, including the space of invariant measures, stable and unstable distributions and foliations, decay of correlations and other statistical properties. There are remarkably few examples up to topological conjugacy, especially in the diffeomorphism setting. Special among them are the algebraic systems, affine systems on homogeneous spaces. In the diffeomorphism case, these are automorphisms of tori and nilmanifolds. Conjecturally, up to topological conjugacy, these account for all Anosov diffeomorphisms (up to finite cover). The case of Anosov flows is

*M.L. was supported by the ERC project 692925 NUHGD of Sylvain Crovisier.
quite different. Here, the algebraic models are suspensions of such diffeomorphisms and geodesic flows on negatively curved rank one symmetric spaces. There are many constructions to give new Anosov flows, all of which come from surgeries of algebraic models. In particular, quite unexpected behaviors are possible, including Anosov flows on connected manifolds which are not transitive, contact flows which are not algebraic, Anosov flows on hyperbolic manifolds.

The algebraic models up to smooth conjugacy are believed to distinguish themselves in many ways, including regularity of dynamical distributions and thermodynamical formalism. In the case of the latter, the first such result was obtained by Katok for geodesic flows of negatively curved surfaces, where it was shown that coincidence of metric entropy with respect to Liouville measure and topological entropy implies that the surface has constant negative curvature [K1, K3]. A weaker version of this was obtained in higher dimensional geodesic flows under nonpositive curvature assumptions by [BCG], which still highly depends on the structures coming from the geometry of the flow. Other generalizations work with broader classes of Anosov flows. Foulon [Fo] showed that in the case of a contact Anosov flow $\Phi$ on a closed three manifold, $\Phi$ is, up to finite cover, smoothly conjugate to geodesic flow of a metric of constant negative curvature on a closed surface if and only if the measure of maximal entropy is the contact volume. In the case of general Anosov flows on compact Riemannian 3-manifolds, one must first assume the existence of a smooth invariant volume measure, which must be the SRB measure (see Subsection 2.2 for more about SRB measures). It is therefore natural to ask the following question:

**Question 1.** Let $\Phi$ be a smooth Anosov flow on a 3-manifold which preserves a smooth volume $\mu$. If $h_{\text{top}}(\Phi) = h_\mu(\Phi)$, is $\Phi$ smoothly conjugate to an algebraic flow?

Our main theorem gives a positive answer to this question:

**Theorem A.** Let $k \geq 5$ be some integer, and let $\Phi$ be a $C^k$ Anosov flow on a compact connected Riemannian 3-manifold $M$ such that $\Phi_* \mu = \mu$ for some smooth volume $\mu$. Then $h_{\text{top}}(\Phi) = h_\mu(\Phi)$ if and only if $\Phi$ is $C^k-\varepsilon$-conjugate to an algebraic flow, for $\varepsilon > 0$ arbitrarily small.

Here, our assumption that the SRB measure is a volume measure is due to the fact that our method relies on some special change of coordinates introduced by Hurder-Katok [HuKa] for volume-preserving Anosov flows, and on Birkhoff Normal Forms for area-preserving maps (see (1.1) below).

Moreover, we believe the theorem is true for $k \geq 2$, but technical obstructions prevent us from finding the precise boundary of required regularity. Let us emphasize that regularity is extremely important for the rigidity phenomenon. If one relaxes to the $C^1$ category, it is possible to produce examples of flows with quite different behaviour. Indeed, given a $C^2$ Axiom A flow on a compact Riemannian manifold and an attractor (see Subsection 2.1 for a definition) whose unstable distribution is $C^1$, Parry [Pa] describes a $C^1$ time change such that for the new flow, the SRB measure of the attractor coincides with the measure of maximal entropy. These measures are obtained as limits of certain closed orbital measures. In particular, for any $C^2$ transitive Anosov flow $\Phi$ on a 3-manifold, the unstable distribution is $C^1$ (see Remark 2.3), hence the synchronization procedure explained by Parry shows that $\Phi$ is $C^1$-orbit equivalent to a $C^1$ Anosov flow for which the SRB measure is equal to the measure of maximal entropy.
The techniques used to prove Theorem A combine several ideas. We do not directly follow the approach of Foulon, who aims to construct a homogeneous structure on the manifold by using a Lie algebra of vector fields tangent to the stable and unstable distributions, together with the vector field generating the flow [Fo]. The central problem in all approaches is the regularity of dynamical distributions. Foulon requires smoothness of the strong stable and unstable distributions, which follows a posteriori from the existence of a smooth conjugacy to an algebraic model, but is often out of reach without additional assumptions, such as a smooth invariant 1-form.

The main technical result of the paper is the smoothness of the weak foliations. For this we use an invariant of Hurder and Katok [HuKa], the Anosov class, which is an idea that can be dated back to Birkhoff and Anosov. In fact, Anosov used this idea to show the existence of examples for which the regularity of the distributions are low: it was first shown that the invariant is non-trivial, but that it must be trivial in all algebraic examples. Hurder and Katok [HuKa] then proved that vanishing of the invariant implies smoothness of the weak stable and unstable distributions. In the case of an Anosov flow obtained by suspending an Anosov diffeomorphism of the 2-torus, they showed that it implies smooth conjugacy to an algebraic model. For more regarding the Anosov class and its connection to normal forms for hyperbolic maps, see Subsection 2.3.

For a conservative Anosov flow on some compact connected 3-manifold, there exists a unique measure of maximal entropy, or MME. If the MME is equal to the volume measure, we are able to show vanishing of the Anosov class. We deduce from [HuKa] that the weak foliations are smooth. This gives a weaker form of rigidity, due to Ghys [G2]: the existence of a smooth orbit equivalence to an algebraic model. This is not surprising, as taking a time change of any Anosov flow will preserve its weak foliations. With this in hand, there is one last lemma to prove: any time change of an algebraic Anosov flow for which the measure of maximal entropy is equivalent to Lebesgue is smoothly conjugate to a linear time change. This is proved in Proposition 3.11.

The difficulty in proving smoothness using local normal forms is that transverse regularity of stable foliations can’t be controlled locally. We circumvent this problem by using an orbit $h_\infty$ homoclinic to a reference periodic orbit $O$, and a sequence $(h_n)_{n \geq 1}$ of periodic orbits with prescribed combinatorics shadowing the orbit $h_\infty$. We are able to control the dynamical and differential properties of the orbits $(h_n)_{n \geq 1}$ by choosing an exceptionally good chart (see Subsection 3.2). On the one hand, in Subsection 3.1, we show that for an Axiom A flow restricted to some basic set (see Subsection 2.1 for the definitions), the equality of the MME and of the SRB measure forces the periodic Lyapunov exponents to be equal; by controlling the periods of the orbits $(h_n)_{n \geq 1}$, this allows us to obtain a first estimate on the Floquet multipliers of the flow for $h_n$, $n \geq 1$. On the other hand, by the choice of the orbits $(h_n)_{n \geq 1}$, we can also study the asymptotics of the Floquet multipliers through the Birkhoff Normal Form of the periodic orbit $O$ (see Subsection 3.2); the calculations are similar to those in [DKL]. Combining those two estimates, we show the following:

**Theorem B.** Let $k \geq 5$ be an integer, and let $\Phi$ be a $C^k$ Anosov flow on a 3-manifold $M$ which preserves a smooth volume $\mu$. If $h_{\text{top}}(\Phi) = h_\mu(\Phi)$, then the Anosov class vanishes identically. Moreover, this implies strong rigidity properties:
(1) the weak stable/unstable distributions of the flow $\Phi$ are of class $C^{k-3}$;
(2) the flow $\Phi$ is $C^k$-orbit equivalent to an algebraic model.

Item (1) follows from the vanishing of the Anosov class and the work of Hurder-Katok [HuKa], while (2) follows from (1) and the work of Ghys [G2].

In order to upgrade the orbit equivalence to a smooth flow conjugacy, we use ideas similar to those in Subsection 3.3 of an unpublished paper [Ya] of Yang; indeed, the equality of the MME and of the volume measure allows us to discard bad situations such as those described in [G1]. In Subsection 3.3, we will prove:

**Theorem C.** Let $\Phi_0$ be an Anosov flow on some 3-manifold that is a smooth time change of an algebraic flow $\Psi_0$. If the measure of maximal entropy of $\Phi_0$ is absolutely continuous with respect to volume, then $\Phi_0$ is a linear time change of $\Psi_0$.

In other words, up to a linear time change, the periods of associated periodic orbits for the flow and the algebraic model coincide. By Livsic’s theorem, this allows us to synchronize the orbit equivalence, and produce a conjugacy between the two flows; the smoothness of this conjugacy is automatic (it follows from previous rigidity results in [dIL]). In particular, Theorem A is a consequence of Theorems B and C.

Besides the rigidity, we also study the entropy flexibility for suspension Anosov flows following the program in [EK] for Anosov systems. We show that the metric entropy with respect to the volume measure and the topological entropy of suspension flow over Anosov diffeomorphisms on torus achieve all possible values subject to a natural normalization.

**Theorem D.** Let $A \in SL(2, \mathbb{Z})$ be a hyperbolic matrix whose induced torus automorphism has topological entropy $h > 0$. Let $\mu$ be the volume measure on $T^2$. Then for any $c_{\text{top}} > c_\mu > 0$ such that $c_\mu \leq h$, there exists a volume-preserving Anosov diffeomorphism $f: T^2 \to T^2$ homotopic to $A$ and a $C^\infty$ function $r: T^2 \to \mathbb{R}^+$ such that $\int r \, d\mu = 1$ and if $\Phi$ is the suspension flow induced by $f$ and $r$, $h_{\text{top}}(\Phi) = c_{\text{top}}$ and $h_\mu(\Phi) = c_\mu$.

Theorem D is optimal – see Subsection 3.4 for the discussion on why it is optimal.

In the last section of this paper (Section 4), we investigate the case of dispersing billiards. The dynamics of such billiards is hyperbolic; moreover, they preserve a smooth volume measure $\mu$, hence they can be seen as an analogue to the conservative Anosov flows on 3-manifolds considered previously; yet, due to the possible existence of grazing collisions, the billiard map has singularities. An orbit with no tangential collisions is called regular. As the billiards under consideration are hyperbolic, recall that for any point $x$ in a regular orbit $O$ of period $p \geq 1$ of the billiard map, there exists a neighbourhood of $x$ where the $p$-th iterate of the billiard map can be conjugate through a $C^\infty$ volume-preserving local diffeomorphism to a unique map

\[ N: (\xi, \eta) \mapsto (\Delta(\xi) \cdot \xi, \Delta(\xi)^{-1} \cdot \eta), \]

called the Birkhoff Normal Form, where $\Delta: z \mapsto \sum_{k=0}^{\infty} a_k z^k$, $|a_0| \in (0, 1)$. For each $k \geq 0$, we call $a_k = a_k(O)$ the $k$-th Birkhoff invariant of $O$, and we say that $N$ is linear if $a_k = 0$, for all $k \geq 1$.

In Subsection 4.2, we study a class of open dispersing billiards satisfying a non-eclipse condition; this class has already been considered in many works ([GR, Mor, 

\[1\]By a slight abuse of notation, we identify $\mu$ with the induced measure on the suspension space.
The dynamics of such billiards is smooth, of type Axiom A, and there exists a unique basic set (see Subsection 2.1 for the definitions). In particular, it has a unique MME and a unique SRB measure, and we show that equality of the MME with the SRB measure forces the first Birkhoff invariant of any periodic orbit to vanish.

In Subsection 4.3, we study $C^\infty$ Sinai billiards with finite horizon, i.e., such that no trajectory makes only tangential collisions. Although the billiard map has singularities, Baladi-Demers [BD] were able to define a suitable notion of topological entropy $h_*$. Moreover, assuming some quantitative lower bound on $h_*$, they showed that there exists a unique invariant Borel probability measure $\mu_*$ of maximal entropy. Our result can then be stated as follows; roughly speaking, it says that if the MME is equal to $\mu$, then the dynamics has strong “rigidity” properties.

**Theorem E.** We consider a $C^\infty$ Sinai billiard with finite horizon satisfying the quantitative condition in [BD] (see (4.1)). If the measure of maximal entropy $\mu_*$ is equal to the volume measure $\mu$, then for any regular periodic orbit with a homoclinic intersection, the associated Birkhoff Normal Form is linear.

In [BD], the authors show that for $\mu_*$ to be equal to $\mu$, it is necessary that the Lyapunov of regular periodic orbits are all equal to $h_*$ (see Proposition 7.13 in [BD]), and observe that no dispersing billiards with this property are known. Compared with theirs, the necessary condition we derive for Birkhoff Normal Forms is more local. Although there is some flexibility for the Birkhoff Normal Forms which can be realized – at least formally – (see for instance the work of Treschev or of Colin de Verdière [CdV, Section 5] in the convex case), the fact it is linear imposes strong geometric restrictions (by [CdV], for symmetric 2-periodic orbits, the Birkhoff Normal Form encodes the jet of the curvature at the bouncing points), and we expect that no Sinai billiard satisfies the conclusion of Theorem E.

**Acknowledgements.** This paper has gone through several stages, and revisions of the author list. The last two authors would like to thank Cameron Bishop and David Hughes for their work on earlier iterations of these results which unfortunately had several defects. They would also like to thank the AMS Mathematical Research Communities program Dynamical Systems: Smooth, Symbolic and Measurable, where several of the initial ideas and work was made on this project. The program also provided travel funds for further collaboration.

The authors would like to thank Viviane Baladi, Aaron Brown, Sylvain Crovisier, Andrey Gogolev, Boris Hasselblatt, Carlos Matheus, Rafael Potrie, Federico Rodriguez-Hertz and Amie Wilkinson for discussions and encouragement on this project. Finally, we would like to acknowledge an unpublished preprint of Jiagang Yang where we learned several useful ideas for the argument in Subsection 3.3.

2. Preliminaries

2.1. General facts about hyperbolic flows. Let us first recall some classical facts about Anosov and Axiom A flows.

In the following, we fix a $C^\infty$ smooth compact Riemannian manifold $M$, and we consider a $C^2$ flow $\Phi = (\Phi^t)_{t \in \mathbb{R}}$ on $M$. We denote by $X_\Phi = X: x \mapsto \frac{d}{dt}|_{t=0} \Phi^t(x)$ the vector field tangent to the direction of the flow. Recall that the nonwandering set
\( \Omega_\Phi = \Omega \subset M \) is the set of points \( x \) such that for any open set \( U \ni x \), any \( T_0 > 0 \), there exists \( T > T_0 \) such that \( \Phi^T(U) \cap U \neq \emptyset \).

**Definition 2.1 (Hyperbolic set).** A \( \Phi \)-invariant subset \( \Lambda \subset M \) without fixed points is called a (uniformly) hyperbolic set if there exists a \( D\Phi \)-invariant splitting

\[
T_x M = E^s(x) \oplus \mathbb{R} X(x) \oplus E^u(x), \quad \forall x \in \Lambda,
\]

where the (strong) stable bundle \( E^s_\Phi = E^s \), resp. the (strong) unstable bundle \( E^u_\Phi = E^u \) is uniformly contracted, resp. expanded, i.e., for some constants \( C > 0 \),

\[
0 \leq \| D_x \Phi^t \cdot v \| \leq C \theta^t \| v \|, \quad \forall x \in \Lambda, \forall v \in E^s(x), \forall t \geq 0,
\]

\[
\| D_x \Phi^{-t} \cdot v \| \leq C \theta^t \| v \|, \quad \forall x \in \Lambda, \forall v \in E^u(x), \forall t \geq 0.
\]

We also denote by \( E^{cs}_\Phi = E^{cs} \), resp. \( E^{cu}_\Phi = E^{cu} \), the weak stable bundle \( E^{cs} := E^s \oplus \mathbb{R} X \), resp. the weak unstable bundle \( E^{cu} := \mathbb{R} X \oplus E^u \).

**Definition 2.2 (Anosov/Axiom A flow).**

- A flow \( \Phi: M \to M \) is called an Anosov flow if the entire manifold \( M \) is a hyperbolic set. In this case, the stable bundle \( E^s_\Phi = E^s \), resp. the unstable bundle \( E^u_\Phi = E^u \) integrates to a continuous foliation \( \mathcal{W}^s_\Phi = \mathcal{W}^s \), resp. \( \mathcal{W}^u_\Phi = \mathcal{W}^u \), called the (strong) stable foliation, resp. the (strong) unstable foliation. Similarly, \( E^{cs} \), resp. \( E^{cu} \) integrates to a continuous foliation \( \mathcal{W}^{cs}_\Phi = \mathcal{W}^{cs} \), resp. \( \mathcal{W}^{cu}_\Phi = \mathcal{W}^{cu} \), called the weak stable foliation, resp. the weak unstable foliation. Moreover, each of these foliations is invariant under the dynamics, i.e., \( \Phi^t(\mathcal{W}^s(x)) = \mathcal{W}^s(\Phi^t(x)) \), for all \( x \in M \) and \(* = s,u,cs,cu\).

- A flow \( \Phi: M \to M \) is called an Axiom A flow if the nonwandering set \( \Omega \subset M \) can be written as a disjoint union \( \Omega = \Lambda \cup F \), where \( \Lambda \) is a closed hyperbolic set where periodic orbits are dense, and \( F \) is a finite union of hyperbolic fixed points.

**Remark 2.3.** Let \( \Phi: M \to M \) be an Anosov flow on some compact connected Riemannian manifold \( M \).

In general the distributions \( E^s_\Phi, * = s,u,cs,cu \), are only Hölder continuous, but if \( \dim M = 3 \), Hirsch-Pugh [HP] have shown that \( E^{cs}_\Phi \) and \( E^{cu}_\Phi \) are of class \( C^1 \).

As we will sometimes need to assume topological transitivity, let us recall that in the case under consideration, namely, a conservative Anosov flow \( \Phi \), transitivity is automatic.

**Theorem 2.4.** For an Axiom A flow \( \Phi \) with a decomposition \( \Omega = \Lambda \cup F \) as above, we have \( \Lambda = \Lambda_1 \cup \cdots \cup \Lambda_m \) for some integer \( m \geq 1 \), where for each \( i \in \{1, \ldots, m\} \), \( \Lambda_i \) is a closed \( \Phi \)-invariant hyperbolic set such that \( \Phi|_{\Lambda_i} \) is transitive, and \( \Lambda_i = \bigcap_{t \in \mathbb{R}} \Phi^t(U_i) \) for some open set \( U_i \supset \Lambda_i \). The set \( \Lambda_i \) is called a basic set of \( \Phi \). A basic set \( \Lambda_i \) is called an attractor if \( \Lambda_i = \bigcap_{t > 0} \Phi^t(V_i) \) for some open set \( V_i \supset \Lambda_i \).

**Definition 2.5 (Algebraic flows).** An Anosov flow \( \Phi: M \to M \) on a 3-dimensional compact Riemannian manifold \( M \) is called algebraic if it is either

1. a suspension of a hyperbolic automorphism of the 2-torus \( \mathbb{T}^2 := \mathbb{R}^2 / \mathbb{Z}^2 \);
2. or a flow on some homogeneous space \( \Gamma \backslash \text{SL}(2, \mathbb{R}) \) corresponding to right translations by diagonal matrices \( \begin{bmatrix} e^t & 0 \\ 0 & e^{-t} \end{bmatrix}, t \in \mathbb{R}, \) where \( \text{SL}(2, \mathbb{R}) \) denotes the universal cover of \( \text{SL}(2, \mathbb{R}) \), and \( \Gamma \) is a uniform subgroup. In other words,
it is the geodesic flow on some closed Riemannian surface of constant negative curvature, or some finite factor of these actions.

2.2. Equilibrium states for Anosov/Axiom A flows. In the following, we recall some classical facts about the equilibrium states of transitive Anosov flows/Axiom A flows, following the presentation given in [C]. For simplicity, we consider the case of a $C^2$ transitive Anosov flow $\Phi: M \to M$ on some $C^\infty$ smooth compact Riemannian manifold, but up to some minor technical details, everything goes through as well for the restriction $\Phi|_\Lambda$ of some $C^2$ Axiom A flow $\Phi$ to some basic set $\Lambda$.

Definition 2.6 (Rectangle, proper family).

- A closed subset $R \subset M$ is called a rectangle if there is a small closed codimension one smooth disk $D \subset M$ transverse to the flow $\Phi$ such that $R \subset D$, and for any $x, y \in R$, the point $[x, y]_R := D \cap W^s_{\Phi, \text{loc}}(x) \cap W^u_{\Phi, \text{loc}}(y)$ exists and also belongs to $R$. A rectangle $R$ is called proper if $R = \text{int}(R)$ in the topology of $D$. For any rectangle $R$ and any $x \in R$, we let $W^s_R(x) := R \cap W^s_{\Phi, \text{loc}}(x)$, $W^u_R(x) := R \cap W^u_{\Phi, \text{loc}}(x)$.

- A finite collection of proper rectangles $\mathcal{R} = \{R_1, \ldots, R_m\}$, $m \geq 1$, is called a proper family of size $\epsilon > 0$ if
  1. $M = \{\Phi^t(S) : t \in [-\epsilon, 0]\}$, where $S := R_1 \cup \cdots \cup R_m$;
  2. $\text{diam}(D_i) < \epsilon$, for each $i = 1, \ldots, m$, where $D_i \supset R_i$ is a disk as above;
  3. for any $i \neq j$, $D_i \cap \{\Phi^t(D_j) : t \in [0, \epsilon]\} = \emptyset$ or $D_j \cap \{\Phi^t(D_i) : t \in [0, \epsilon]\} = \emptyset$.

The set $S$ is called a cross-section of the flow $\Phi$; it is associated with a Poincaré map $F: S \to S$, where for any $x \in S$, $F(x) = \Phi^\tau(x)$, the function $\tau: S \to \mathbb{R}_+$ being the first return time on $S$.

In the following, given a proper family $\mathcal{R} = \{R_1, \ldots, R_m\}$, $m \geq 1$, for $*=s,u$, and for any $x \in R_i$, $i \in \{1, \ldots, m\}$, we will also set $W^*_F(x) = W^*_F,\text{loc}(x) := W^*_R(x)$.

Definition 2.7 (Markov family). Given $\epsilon > 0$ small and $m \geq 1$, a proper family $\mathcal{R} = \{R_1, \ldots, R_m\}$ of size $\epsilon$, with Poincaré map $F$, is called a Markov family if it satisfies the following Markov property: for any $x \in \text{int}(R_i) \cap F^{-1}(\text{int}(R_j))$, $i, j \in \{1, \ldots, m\}$, it holds

$$W^s_{R_i}(x) \subset F^{-1}(W^s_{R_j}(F(x))) \quad \text{and} \quad F(W^u_{R_i}(x)) \supset W^u_{R_j}(F(x))$$

Theorem 2.8 (see Theorem 4.2 in [C]). Any transitive Anosov flow has a Markov family of arbitrary small size; the same is true for the restriction of an Axiom A flow to any basic set.

Proposition 2.9 (see Proposition 4.6 in [C]). Let $p: M \to \mathbb{R}$ be a Hölder continuous function. Then there exists a unique equilibrium state $\mu_p$ for the potential $p$; in other words, $\mu_p$ is the unique $\Phi$-invariant measure which achieves the supremum

$$P_p := \sup_{\Phi_* \mu = \mu} \left( h_{\mu}(\Phi) + \int_M p \, d\mu \right) = h_{\mu_p}(\Phi) + \int_M p \, d\mu_p.$$ 

Here, the supremum is taken over all $\Phi$-invariant measures $\mu$ on $M$; we call $P_p$ the topological pressure of the potential $p$ with respect to the flow $\Phi$. 

Proposition 2.10 (see Proposition 4.7 in [C], and also Proposition 4.5 in [Bo] for the diffeomorphisms case). Two equilibrium states $\mu_{p_1}$ and $\mu_{p_2}$ associated to Hölder potentials $p_1, p_2: M \to \mathbb{R}$ coincide if and only if for any Markov family $\mathcal{R}$, the functions

$$G_i: x \mapsto \int_0^{\tau(x)} p_i(\Phi^t(x)) \, dt - P_{p_i} \times \tau(x), \quad i = 1, 2,$$

are cohomologous on $S$, where $S$ denotes the cross section associated to $\mathcal{R}$, and $\tau: S \to \mathbb{R}_+$ is the first return time on $S$. In other words, there exists a Hölder continuous function $u: S \to \mathbb{R}$ such that

$$G_2(x) - G_1(x) = u \circ F(x) - u(x), \quad \forall x \in S,$$

where $F: x \mapsto \Phi^{\tau(x)}(x)$ is the Poincaré map induced by $\Phi$ on $S$.

As a direct corollary of Proposition 2.10, we have:

Corollary 2.11. If two equilibrium states $\mu_{p_1}$ and $\mu_{p_2}$ associated to Hölder potentials $p_1, p_2: M \to \mathbb{R}$ coincide, then for any periodic orbit $O = \{\Phi^t(x)\}_{t \in [0, L(O)]}$ of period $L(O) = L(x) > 0$, we have

$$\int_0^{L(O)} p_1(\Phi^t(x)) \, dt - P_{p_1} \times L(O) = \int_0^{L(O)} p_2(\Phi^t(x)) \, dt - P_{p_2} \times L(O).$$

Let us recall that a Sinai-Ruelle-Bowen measure, or SRB measure for short, is a $\Phi$-invariant Borel probability measure $\mu$ that is characterized by the property that $\mu$ has absolutely continuous conditional measures on unstable manifolds (see for instance [Yo] for a reference). For an Anosov flow on some compact connected Riemannian manifold which preserves a smooth volume, the volume measure is the unique SRB measure. When volume is not preserved, SRB measures are the invariant measures most compatible with volume.

A measure of maximal entropy, or MME for short, is a $\Phi$-invariant probability measure $\nu$ which maximizes the metric entropy, i.e., such that $h(\Phi) = h_{\text{top}}(\Phi)$.

Let us recall that both the SRB measure and MME can be characterized as equilibrium states (see for instance [C] for a reference):

Proposition 2.12 (SRB measure/metric of maximal entropy).

- There exists a unique SRB measure for the flow $\Phi$; it is the unique equilibrium state associated to the geometric potential

$$p^\nu: x \mapsto -\frac{d}{dt}|_{t=0} \log J_x^\nu(t),$$

where $J_x^\nu(t)$ is the Jacobian of the map $D\Phi^t: E^u(x) \to E^u(\Phi^t(x))$. Moreover, the pressure for this potential vanishes, i.e., $P_{p^\nu} = 0$.

- There exists a unique MME for the flow $\Phi$; it is the unique equilibrium state for the zero potential $p = 0$. In particular, by the variational principle, the associated pressure is equal to the topological entropy, i.e., $P_0 = h_{\text{top}}(\Phi)$.

2.3. Anosov class and Birkhoff Normal Form. In this subsection, we recall some general notions about obstructions to the regularity of the dynamical foliations of Anosov flows on 3-manifolds, in particular, the notion of Anosov class; we follow the exposition of [HuKa].
Let $M$ some $C^\infty$ smooth Riemannian manifold $M$ of dimension three which supports a $C^k$ volume-preserving Anosov flow $\Phi = (\Phi^t)_{t \in \mathbb{R}}$, for some integer $k \geq 3$. As previously, we denote by $X_{\Phi} = X := \frac{d}{dt}|_{t=0} \Phi^t$ the flow vector field, and we let $dv := x_{\Phi} \text{Vol}$.

**Definition 2.13** (Adapted transverse coordinates, see [HuKa]). For some small $\varepsilon > 0$, we say that a $C^1$ map $\Psi: M \times (-\varepsilon, \varepsilon)^2 \to M$ defines $C^k$-adapted transverse coordinates for the flow $\Phi$ if for each $x \in M$:

1. the map $\Psi_x: (-\varepsilon, \varepsilon)^2 \to M$, $(\xi, \eta) \mapsto \Psi(x, \xi, \eta)$ is a $C^k$ diffeomorphism and the vectors $\partial_x \Psi_x, \partial_\eta \Psi_x$ are uniformly transverse to $X$; in particular, $S_x := \Psi_x((-\varepsilon, \varepsilon)^2)$ is a uniformly embedded transversal to the flow;
2. the maps $\Psi_x(\cdot, 0)$, $\Psi_x(0, \cdot)$ are coordinates respectively onto the stable manifold $W^s_{S_x}(x)$ and the unstable manifold $W^u_{S_x}(x)$ at $x$ and depend in a $C^1$ fashion on $x$, when considered as $C^k$ immersions of $(-\varepsilon, \varepsilon)$ into $M$;
3. the $C^1$ foliation $W^s_{S_x}$, resp. $W^u_{S_x}$, obtaining by restricting the weak stable foliation $W^s_{\Phi}$, resp. weak unstable foliation $W^u_{\Phi}$, to $S_x$ is $C^1$-tangent at $x$ to the linear foliation of $S_x$ by the coordinate lines parallel to the horizontal axis, resp. vertical axis, in the coordinates provided by $\Psi_x$;
4. the restriction of $dv$ to $S_x$ satisfies $\Psi_x^*(dv) = d\xi \wedge d\eta$.

**Proposition 2.14** (Proposition 4.2 in [HuKa]). For any $k \geq 3$, $C^{k-1}$-adapted transverse coordinates exist for a volume-preserving Anosov flow on a closed 3-manifold.

Let $V$ be a vector field on $M$. For each point $x \in M$, the restriction of $V$ to $S_x$ is projected onto $T S_x$, and then expressed in the local coordinates as $(\xi, \eta) \mapsto (V^1_\xi(\xi, \eta), V^2_\xi(\xi, \eta))$. We denote by $V_x := V(\cdot, 0)$ the restriction of this vector field to the horizontal axis.

We let $\hat{V}_x$ be the local vector field at $x$ along the stable manifold through $x$ obtained from $V_x$ by pointwise scaling so that in coordinates we have $\hat{V}_x: z \mapsto (a_{V,x}(z), 1)$. We consider the expansion of $a_{V,x}$ near 0:

$$a_{V,x}(z) = a^0_{V,x} + a^1_{V,x}z + z b_{V,x}(z) + o(z^2),$$

where $a^0_{V,x}, a^1_{V,x} \in \mathbb{R}$, and $b_{V,x}$ is continuous and vanishes at 0.

In the following, we let $V^*$ be a vector field such that $a^0_{V^*,x} = 0$ for any $x \in M$, which corresponds to the case of the weak unstable distribution. Let $\pi_X: TM \to TM$ be the fiberwise projection map onto the subbundle of vectors orthogonal to $X$, and for any $(x,t) \in M \times \mathbb{R}$, let $\lambda^x(t) \in \mathbb{R} \setminus \{0\}$ be defined as

$$\pi_X \circ D\Phi^t(V^*)(\Phi^t(x)) = \lambda^x(t)V^*(\Phi^t(x)).$$

Let us recall the notions of cocycle and coboundary over a flow.

**Definition 2.15** (Cocycle/coboundary). A map $C: M \times \mathbb{R} \to \mathbb{R}$ is a called a $C^1$ cocycle over the flow $\Phi$ if it is of class $C^1$ and satisfies

$$C(x, t + s) = C(x, t) + C(\Phi^t(x), s), \quad \forall x \in M, \forall t, s \in \mathbb{R}.$$

A $C^1$ cocycle $B: M \times \mathbb{R} \to \mathbb{R}$ over $\Phi$ is a $C^1$ coboundary if there exists a $C^1$ function $u: M \to \mathbb{R}$ such that

$$(2.1) \quad B(x, t) = u \circ \Phi^t(x) - u(x), \quad \forall x \in M, \forall t \in \mathbb{R}.$$

$^2$By Livsic’s theorem, it is sufficient to have a $C^0$ function $u: M \to \mathbb{R}$ such that (2.1) holds.
The $C^1$-cohomology class of a $C^1$ cocycle $C: M \times \mathbb{R} \to \mathbb{R}$ over $\Phi$ is the image of $C$ in the group of $C^1$ cocycles over $\Phi$ modulo the $C^1$ coboundaries.

**Lemma 2.16** (Anosov cocycle/class, see Lemma 5.1, Proposition 5.3 in [HuKa]). For any $(x, t) \in M \times \mathbb{R}$, we denote by $\tilde{V}^*_{x,t}$ the rescaled image of $V^*_{x,t}$ by the Poincaré map of $\Phi$ from $S_x$ to $S_{\Phi^t(x)}$, so that $\tilde{V}^*_{x,t}: z \mapsto (av^*_{x,t}(z), 1)$. For $|z| \ll 1$, we have
\[
a v^*_{x,t}(z) = (\lambda^*)^{-1} a_{\lambda^*}^* z + (\lambda^*)^{-1} z b v^*_{x,t}(\lambda^* z) + A_{\Phi}(x,t) z^2 + o(z^3),\]
where $\lambda^* = \lambda^*(x,t) \neq 0$, and $A_{\Phi}(x,t) \in \mathbb{R}$. Then, the map $A_{\Phi}: M \times \mathbb{R} \to \mathbb{R}$ is a $C^1$ cocycle over the flow $\Phi$, called the Anosov cocycle.

The Anosov class $[A_{\Phi}]$ is defined as the $C^1$-cohomology class of $A_{\Phi}$; it is independent of the choice of the Riemannian metric on $TM$ and $C^k$-adapted transverse coordinates.

Let us now consider the case where $x$ is a point in some periodic orbit $O$ for $\Phi$ of period $\mathcal{L}(O) = \mathcal{L}(x) > 0$. We let $\Psi$ be $C^k$-transverse coordinates for $\Phi$ according to Definition 2.13, and we let $S_x$ be the associated transverse section to $\Phi$ at $x$, endowed with local coordinates $(\xi, \eta)$, the point $x$ being identified with the origin $(0,0)$. The Poincaré map $\mathcal{F}$ induced by the flow $\Phi$ on $S_x$ is a local diffeomorphism defined in a neighbourhood of $(0,0)$, and preserves the volume $d\nu = i_x \text{Vol}$. It has a saddle fixed point at $(0,0)$ with eigenvalues $0 < \lambda < 1 < \lambda^{-1}$, and is written in coordinates as
\[
\mathcal{F}: (\xi, \eta) \mapsto (\lambda \xi + \mathcal{F}_1(\xi, \eta), \lambda^{-1} \eta + \mathcal{F}_2(\xi, \eta)).
\]
In fact, assuming that $S_x$ is chosen sufficiently small, then for $k = \infty$, by a result of Sternberg [Ste], there exists a $C^\infty$ volume-preserving change of coordinates $R_0: S_x \to \mathbb{R}^2$ which conjugates $\mathcal{F}$ to its Birkhoff Normal Form $N = R \circ \mathcal{F} \circ R^{-1}$:
\[
N = N_\Delta: (\xi, \eta) \mapsto (\Delta(\xi \eta) \cdot \xi, \Delta(\xi \eta)^{-1} \cdot \eta),
\]
for some (unique) function
\[
\Delta: z \mapsto \sum_{k=0}^{+\infty} a_k z^k, \quad a_0 = \lambda \neq 0.
\]
The numbers $(a_k)_{k \geq 0} = (a_k(O))_{k \geq 0}$ are called the Birkhoff invariants or coefficients at $O$ of $\mathcal{F}$.

This has later been generalized to the case of finite regularity $k \geq 3$ in several works (see for instance [GST] and [DGG]). In particular, there exists a $C^k$ change of coordinates $R: S_x \to \mathbb{R}^2$ under which $\mathcal{F}$ takes the form
\[
\mathcal{F}: (\xi, \eta) \mapsto (\lambda \xi + a_1 \xi^2 \eta + o(\xi^2), \lambda^{-1} \eta - a_1 \xi \eta^2 + o(\xi \eta^2)).
\]

By a direct calculation, we have the following identity between the Anosov cocycle and the first Birkhoff invariant at $O$: (see formula (16) in Hurder-Katok [HuKa])
\[
(2.2) \quad A_{\Phi}(x, \mathcal{L}(x)) = \frac{1}{2} \lambda \partial_{\xi \eta} \mathcal{F}_2(0,0) = -\frac{1}{2} \lambda^{-1} \partial_{\eta \xi} \mathcal{F}_1(0,0) = -\lambda^{-1} a_1.
\]

The following result of Hurder-Katok says that the Anosov class corresponds to certain obstructions to the smoothness of the weak stable/weak unstable distributions. Moreover, by Livsic’s Theorem, the Anosov class $[A_{\Phi}]$ vanishes if and only if $A_{\Phi}(x, \mathcal{L}(x)) = 0$ for any periodic point $x$ of period $\mathcal{L}(x) > 0$. In other words, it is sufficient to consider what happens at periodic points, and in view of (2.2), the periodic obstructions can be characterized in terms of the first Birkhoff invariant.
Theorem 2.17 (Theorem 3.4, Corollary 3.5, Proposition 5.5 in [HuKa]). Let us assume that \( k \geq 5 \). The following properties are equivalent:

- the Anosov class \([A_{\Phi}]\) vanishes;
- for any periodic orbit \( O \), the first Birkhoff invariant at \( O \) vanishes;
- the weak stable/weak unstable distributions \( E_{cs}^{\Phi}/E_{cu}^{\Phi} \) are \( C^{k-3} \).

Besides, by the work of Ghys, we know that high regularity of the dynamical distributions implies that the flow is orbit equivalent to an algebraic model:

Theorem 2.18 (Théorème 4.6 in [G2]). Let \( \Phi: M \to M \) be a \( C^k \) Anosov flow on some 3-manifold \( M \), for some integer \( k \geq 2 \). If \( W_{cu}^{\Phi} \) and \( W_{cs}^{\Phi} \) are of class \( C^{1,1} \), then \( \Phi \) is \( C^k \)-orbit equivalent to an algebraic flow.

3. Entropy rigidity for conservative Anosov flows on 3-manifolds

3.1. Periodic Lyapunov exponents when SRB=MME. Let \( M \) be a \( C^\infty \) smooth compact Riemannian manifold of dimension 3. Given an integer \( k \geq 2 \), we consider the restriction \( \Phi|_{\Lambda} \) of some \( C^k \) Axiom A flow \( \Phi: M \to M \) to some basic set \( \Lambda \subset M \) (or a \( C^k \) Anosov flow \( \Phi \)). Moreover, we assume that \( \Phi_*\mu = \mu \) for some smooth volume measure \( \mu \) (in particular, in the case where \( \Phi \) is Anosov, it is transitive). Equivalently\(^3\), for any periodic orbit \( O = \{ \Phi^t(x) \}_{t \in [0, L(O)]} \) of period \( L(O) = L(x) > 0 \), the map \( D_x \Phi^{L(x)}: T_xM \to T_xM \) has determinant one. In particular, the Lyapunov exponent of the orbit \( O \) is equal to

\[
\text{LE}(O) = \text{LE}(x) = \frac{1}{L(x)} \log J^u_x(L(x)).
\]

Moreover, by Proposition 2.12, there exist a unique SRB measure for \( \Phi|_{\Lambda} \) (when \( \Phi \) is Anosov, this SRB measure is equal to \( \mu \)) and a unique measure of maximal entropy (MME). Combining Corollary 2.11 and Proposition 2.12, we deduce:

**Proposition 3.1.** If the SRB measure is equal to the MME, then the Lyapunov exponents of periodic orbits are constant, i.e., for any periodic orbit \( O \), we have

\[
\text{LE}(O) = h_{\text{top}}(\Phi).
\]

Equivalently, for any \( x \in O \), and if \( L(O) = L(x) > 0 \) is the period of \( O \), it holds

\[
J^u_x(L(x)) = e^{h_{\text{top}}(\Phi)L(x)}.
\]

**Proof.** By Proposition 2.12, the SRB measure and the MME are respectively associated to the potentials \( p^u \) and \( \Phi \), and to the pressures 0 and \( h_{\text{top}}(\Phi) \). We deduce from Corollary 2.11 that for any periodic orbit \( O = \{ \Phi^t(x) \}_{t \in [0, L(O)]} \) of period \( L(O) = L(x) > 0 \), it holds \( \log J^u_x(L(x)) = h_{\text{top}}(\Phi)L(x) \), which concludes.

In Appendix A, we outline another approach for topologically mixing Anosov flows, based on the properties of the Bowen-Margulis measure.

---

\(^3\)See for instance Theorem 4.14 in [Bo].
3.2. Expansion of the Lyapunov exponents of periodic orbits in a horseshoe with prescribed combinatorics. Let $M$ and $\Phi$ be as in Subsection 3.1. The goal in this subsection is to derive asymptotics on the Lyapunov exponents of certain periodic orbits in the horseshoe associated to some homoclinic intersection between the weak stable and weak unstable manifolds of some reference periodic point. For this, we select a sequence of periodic orbits accumulating the given periodic point with a prescribed combinatorics.

In the following, we take a Markov family $R$ for $\Phi$ associated to some cross section $S$, and we denote by $F$ the Poincaré map induced by $\Phi$ on $S$. Let $x \in S$ be a point in some periodic orbit $O = \{\Phi^t(x)\}_{t \in [0,L(O)]}$ of period $L(O) = L(x) > 0$. We consider a point $x_\infty \in S$ such that $x \in W^s_\Phi(x) \cap W^u_\Phi(x)$. In particular, the orbit $h_\infty$ of $x_\infty$ is homoclinic to the periodic orbit $O$. It is well-known that this tranverse homoclinic intersection generates a horseshoe which admits a symbolic coding (see for instance [HaKa, Theorem 6.5.5]). Let $S_0 \subset S$ be a small neighbourhood of the periodic point $x$ encoded by the symbol 0, and let $S_1 \subset S$ be a small neighbourhood of the homoclinic point $x_\infty$ encoded by the symbol 1. After possibly replacing $F$ with some iterate $F^p$, $p \geq 1$, the symbolic coding associated to $x_\infty$ is

$$x_\infty \longleftrightarrow \ldots \uparrow 0000 \ldots$$

Let us select the sequence $(h_n)_{n \geq 1}$ of periodic orbits in the horseshoe whose (periodic) symbolic coding is given by

$$h_n \longleftrightarrow \ldots |0\ldots 01|0\ldots 01|0\ldots 01|\ldots$$

In particular, for each $n \geq 1$, $h_n$ is periodic for the Poincaré map $F$, of period $n + 1$.

After going to a chart, we endow $S_0$ with local coordinates. We denote by $x^1_\infty$, resp. $x^2_\infty$, the coordinates of the point of $h_\infty$ in $S_0$ encoded by the symbolic sequence

$$x^1_\infty \longleftrightarrow \ldots \uparrow 000010000\ldots, \quad \text{resp.} \quad x^2_\infty \longleftrightarrow \ldots \uparrow 000010000\ldots$$

Similarly, for any integer $n \geq 1$, we denote by $x^1_n$, resp. $x^2_n$, the coordinates of its periodic approximation in $h_n$, encoded by the symbolic sequence

$$x^1_n \longleftrightarrow \ldots |0\ldots 01|0\ldots 01|\ldots, \quad \text{resp.} \quad x^2_n \longleftrightarrow \ldots |0\ldots 01|0\ldots 01|\ldots$$

![Figure 1. Selection of the periodic orbits $h_n$.](image-url)
Note that the points $x_1^\infty, x_1^n$, resp. $x_2^\infty, x_2^n$ share the same symbolic past and future for $n - 1$ steps, hence by hyperbolicity, they are exponentially close in phase space for $n \gg 1$ large. See Figure 1 for an illustration.

The point $x$ is a saddle fixed point under $\mathcal{F}$, with eigenvalues $0 < \lambda < 1 < \lambda^{-1}$. The restriction of $\mathcal{F}$ to $S_0$ is a local volume-preserving diffeomorphism. As recalled in Subsection 2.3, if $S_0$ is chosen sufficiently small, then there exists a $C^k$ change of coordinates $R: S_0 \to \mathbb{R}^2$ under which $\mathcal{F}$ takes the form

$$N = N_\Delta: (\xi, \eta) \mapsto (\Delta(\eta)\xi, \Delta(\xi)\eta^{-1} \eta),$$

for some $C^k$ function $\Delta: \mathbb{R} \to \mathbb{R}$ such that $\Delta(z) = \lambda + a_1 z + o(z)$ for $|z| \ll 1$, where $a_1 = a_1(\mathcal{O})$ is the first Birkhoff invariant at $\mathcal{O}$ of $\mathcal{F}$. For $k = \infty$, $\Delta$ is $C^\infty$, and $N$ is the Birkhoff Normal Form of $\mathcal{F}$.

For simplicity, in the following, we only detail the case where $k = \infty$, but the case of finite regularity $k \geq 5$ is handled similarly.

**Lemma 3.2.** The conjugacy $R$ can be chosen in such a way that for all $n \geq 1$,

$$R(x_1^n) = (\eta_n, \xi_n) \in \Gamma_1, \quad R(x_2^n) = (\xi_n, \eta_n) \in \Gamma_2,$$

where $\Gamma_1, \Gamma_2$ are two smooth arcs which are mirror images of each other under the reflection with respect to the first bissectrix $\{\xi = \eta\}$.

**Proof.** Let $\tilde{R}$ be any $C^\infty$ volume-preserving map such that $N = \tilde{R} \circ \mathcal{F} \circ (\tilde{R})^{-1}$. Inside $S_0$, we have a foliation $\mathcal{H}$ by curves along which the motion happens, which corresponds to the preimage of the foliation by the hyperbolas $\{\xi \eta = \text{cst}\}$ under $\tilde{R}$.

Let us consider the square of the Poincaré map $\mathcal{F}$ restricted to a small neighbourhood $S_0^1 \subset S_0$ of $x_1^\infty$. It follows from the definition of $x_1^\infty, x_2^\infty$ that $\mathcal{F}^2$ maps $S_0^1 \subset S_0$ to a small neighbourhood $S_0^2 \subset S_0$ of $x_2^\infty$. The leaf of $\mathcal{H}$ through $x_1^\infty$ coincides with the local unstable leaf $W^u_{\mathcal{F}, \text{loc}}(x_1^\infty) \subset W^u\mathcal{F}(x)$, while the leaf of $\mathcal{H}$ through $x_2^\infty$ coincides with the local stable leaf $W^s_{\mathcal{F}, \text{loc}}(x_2^\infty) \subset W^s\mathcal{F}(x)$. In particular, locally, the leaves of the foliation $\mathcal{H} \cap S_0^1$ are close to the unstable leaf $W^u_{\mathcal{F}, \text{loc}}(x_1^\infty)$, while the leaves of $\mathcal{H} \cap S_0^2$ are close to the stable leaf $W^s_{\mathcal{F}, \text{loc}}(x_2^\infty)$. Besides, due to the presence of the homoclinic intersection between $W^u\mathcal{F}(x)$ and $W^s\mathcal{F}(x)$, the image under $\mathcal{F}^2$ of $W^u_{\mathcal{F}, \text{loc}}(x_1^\infty)$ intersects $W^s_{\mathcal{F}, \text{loc}}(x_2^\infty)$ transversally. We conclude that the foliation $\mathcal{F}^2(\mathcal{H} \cap S_0^1) = \{\mathcal{F}^2(\mathcal{H}_1^1)\}_t$ is transverse to the foliation $\mathcal{H} \cap S_0^2 = \{\mathcal{H}_2^2\}_t$, provided that $S_0^1, S_0^2$ are chosen sufficiently small, where for $|t| \ll 1$, $\mathcal{H}_1^1$ denotes the leaf of the foliation $\mathcal{H} \cap S_0^1$ coming from the hyperbola $\{\xi \eta = t\}$, and $\mathcal{H}_2^2$ denotes the leaf of the foliation $\mathcal{H} \cap S_0^2$ coming from the same hyperbola $\{\xi \eta = t\}$. Since the foliation $\mathcal{H}$ is smooth (it is the image under $\tilde{R}$ of the foliation $\{\xi \eta = \text{cst}\}$), the locus of intersection $\{\mathcal{F}^2(\mathcal{H}_1^1) \cap \mathcal{H}_2^2\}_{|t| \ll 1}$ is a $C^\infty$ curve $\tilde{\Gamma}_2$ containing the point $x_2^\infty$. Similarly, we denote by $\tilde{\Gamma}_1$ the locus of intersection of $\mathcal{F}^{-2}(\mathcal{H}_2^2)$ and $\mathcal{H}_1^1$ near the point $x_1^\infty$ (see Figure 1).

Let us denote by $\tilde{\Gamma}_1$ and $\tilde{\Gamma}_2$ the respective images of the arcs $\tilde{\Gamma}_1$ and $\tilde{\Gamma}_2$ under $\tilde{R}$. For any $C^\infty$ function $D$, the map $N_D: (\xi, \eta) \mapsto (D(\xi \eta) \cdot \xi, D(\xi \eta)^{-1} \cdot \eta)$ commutes with $N$, hence $N_D \circ \tilde{R}$ also conjugates $\mathcal{F}$ with its Birkhoff Normal Form. By replacing $\tilde{R}$ with $N_D \circ \tilde{R}$ for some suitable function $D$, without loss of generality, we may assume that locally, $\tilde{\Gamma}_1 = \{(\xi, \tilde{\gamma}_1(\xi))_\xi, \text{ resp. } \tilde{\Gamma}_2 = \{(\xi, \tilde{\gamma}_2(\xi))_\xi, \text{ is a graph near } \tilde{R}(x_1^\infty) =: (0, \tilde{\xi}_1^\infty), \text{ resp. } \tilde{R}(x_2^\infty) =: (\tilde{\xi}_2^\infty, 0). \text{ Let us look for } D \text{ such that } N_D(\tilde{\Gamma}_1) = \{(D(\xi \tilde{\gamma}_1(\xi))_\xi, D(\xi \tilde{\gamma}_1(\xi))^{-1} \tilde{\gamma}_1(\xi))_\xi \text{ and } N_D(\tilde{\Gamma}_2) = \{(D(\xi \tilde{\gamma}_2(\xi))_\xi, D(\xi \tilde{\gamma}_2(\xi))^{-1} \tilde{\gamma}_2(\xi))_\xi \text{ for some suitable function } D. \}.$
\{(D(\xi_2(\xi))\xi, D(\xi_2(\xi))^{-1}(\xi_2(\xi))\}\xi are mirror images of each other under the involution \(I_0: (\xi, \eta) \mapsto (\eta, \xi)\). As the latter preserves hyperbolas \(\{\xi \eta = \text{cst}\}\), this happens if and only if

\[ D(\xi_1(\xi))^{-1}(\xi_1(\xi)) = D(\xi_2(\xi))\hat{\xi}, \]

where \(\hat{\xi} = \xi(\xi)\) is the unique number such that \(\hat{\xi}^2(\xi) = \xi_1^1(\xi)\). Note that for \(|\xi|\) small, i.e., for \((\xi, \xi_1^1(\xi))\) close to \(R(x_1^\infty) = (0, \xi_1^\infty)\), the existence of \(\hat{\xi}(\xi)\) is guaranteed by the implicit function theorem. Indeed, by the transverse intersection between the stable and the unstable manifolds at \(x_2^\infty\), we have \(\hat{\xi}_1^2(\xi_2^\infty) \neq 0\); moreover, the map \(\xi \mapsto \hat{\xi}(\xi)\) is smooth. The previous equation thus yields

\[ D(\xi_1(\xi)) = \frac{\hat{\xi}_1(\xi)}{\xi(\xi)}. \]

As \(\lim_{\xi \to 0} \hat{\xi}_1(\xi) = \xi_1^\infty \neq 0\) and \(\lim_{\xi \to 0} \hat{\xi}(\xi) = \xi_2^\infty \neq 0\), and since \(\hat{\xi}_1'(0) \neq 0\), the function \(\xi \mapsto D(\xi)\) it defines is smooth near \(0\), and the associated change of coordinates \(R := N_D \circ R\) satisfies the desired conditions. \(\square\)

![Figure 2. Periodic orbits in Birkhoff coordinates.](image-url)

In the following, we fix a conjugacy map \(R\) as given by Lemma 3.2. We denote by \(W_1^2 \subset R(S_1^2)\) the arc of the stable manifold through \(R(x_1^1) = (0, \xi_1^\infty)\), and we let \(W_2^2 \subset R(S_2^2)\) be the arc of the unstable manifold through \(R(x_2^2) = (\xi_2^\infty, 0)\). See Figure 2 for an illustration.

**Lemma 3.3.** The arcs \(\Gamma_1, W_1^1\) and \(\{(0, \xi_1^\infty + \eta) : |\eta| \ll 1\}\) are pairwise transverse at \((0, \xi_1^\infty)\).

**Proof.** The last two arcs are transverse because they are pieces respectively of the stable and of the unstable manifold of the origin. In the following, we assume that \(\Gamma_1 = \{(\eta, \gamma(\eta)) : |\eta| \ll 1\}\) is the graph of some smooth function \(\gamma\) and show that it is transverse to \(W_1^1\) at \((0, \xi_1^\infty)\). The other case is handled similarly.
Lemma 3.7. As \( n \to +\infty \), we have the asymptotic expansion
\[
\text{tr}(D\mathcal{F}^{n+1}_{x_n}) = C_0 \lambda^{-n} + nC_1 a_1 + O(1),
\]
where \( C_0, C_1 \in \mathbb{R}^* \) are nonzero constants, and \( a_1 \in \mathbb{R} \) is the first Birkhoff invariant at \( \mathcal{O} \) of \( \mathcal{F} \).

\footnote{They are also equal to the eigenvalues of \( D\mathcal{F}^{n+1}_{x_n} \), see for instance Lemma 1 on p.111 of [HZ].}
Proof. We use the fact that the trace $\text{tr}(DF_{x}^{n+1})$ is invariant under the change of coordinates $R$. Therefore, we can replace the dynamics of $F$ with that of the Birkhoff Normal Form $N$ and some gluing map $\mathcal{G} = R \circ F^{2} \circ R^{-1}$ from an open subset of $R(S^{2}_{\infty})$ to $R(S^{2}_{\infty})$. In particular, for any integer $n \geq 1$, it holds

$$N^{n-1} \circ \mathcal{G}(\eta_{n}, \xi_{n}) = N^{n-1}(\xi_{n}, \eta_{n}) = (\Delta(\xi_{n})\eta_{n})^{n-1} \xi_{n}, \Delta(\xi_{n})^{-n} \eta_{n}) = (\eta_{n}, \xi_{n}),$$

and $\text{tr}(DF_{x}^{n+1}) = \text{tr}(D(N^{n-1} \circ \mathcal{G})(\eta_{n}, \xi_{n}))$. Moreover, the expansion in (3.4) of the first order terms of $\text{tr}(DF_{x}^{n+1})$ follows from Lemma 4.10 of [DKL]. In particular, the constant $C_{1} \in \mathbb{R}$ in (3.4) is given by

$$C_{1} := -2\lambda^{-1}\xi_{\infty}^{2}g_{0},$$

where the constant $g_{0} \in \mathbb{R}$ is defined by: (see formula (4.4) in [DKL])

$$DG_{(0,\xi_{\infty})} = \begin{bmatrix} \gamma_{1}(2 - \gamma_{1}g_{0}) & \gamma_{1}g_{0} - 1 \\ 1 - \gamma_{1}g_{0} & g_{0} \end{bmatrix},$$

where $\gamma_{1} := \gamma'(0)$ is the derivative at 0 of the function $\gamma$ such that $\Gamma_{1} = \{(\eta, \gamma(\eta)) : |\eta| < 1\}$. As the gluing map $\mathcal{G}$ is dynamically defined, the vector $(1, w_{1})$ tangent to $W_{\infty}^{s}$ at $(0, \xi_{\infty})$ is mapped to a vector $(1, 1 - g_{0}(\gamma_{1} - w_{1}))$ in the stable subspace at $(\xi_{\infty}, 0)$, which is horizontal in our coordinate system. We deduce that $g_{0}(\gamma_{1} - w_{1}) = 1$, and by Lemma 3.3, $w_{1} \neq \gamma_{1} \neq \infty$, so that

$$g_{0} = (\gamma_{1} - w_{1})^{-1} \neq 0,$$

hence $C_{1} \neq 0$. \hfill $\Box$

Corollary 3.8. If the SRB measure is equal to the MME, then for any periodic orbit $O$, the first Birkhoff invariant at $O$ of the Poincaré map $F$ vanishes.

Proof. Let us consider the periodic point $x$ as above; we use the notations introduced previously. By equating the expressions obtained in (3.3) and (3.4), we obtain

$$\text{tr}(DF_{x}^{n+1}) = C_{-1}^{n}\lambda^{-n} + O(1) = C_{0}\lambda^{-n} + nC_{1}a_{1} + O(1).$$

Since $C_{1} \neq 0$, we deduce that $a_{1} = 0$, as desired. \hfill $\Box$

By Theorem 2.17, we deduce:

Corollary 3.9. If the SRB measure is equal to the MME, then the Anosov class $[A_{\Phi}]$ vanishes.

Gathering the previous observations, we thus obtain:

Corollary 3.10. Let $k \geq 5$ be some integer, and let $\Phi$ be a volume-preserving $C^{k}$ Anosov flow on some 3-dimensional compact connected Riemannian manifold $M$.

(1) If the MME of $\Phi$ is equal to the volume measure, then the weak stable/unstable distributions $E^{s}_{\Phi}/E^{u}_{\Phi}$ are $C^{k-3}$.

(2) If the MME of $\Phi$ is equal to the volume measure, then $\Phi$ is $C^{k}$-orbit equivalent to an algebraic flow.

(3) If $\Phi$ is obtained by suspending an Anosov diffeomorphism $F$ of the 2-torus $T^{2}$, then the MME of $\Phi$ is equal to the volume measure if and only if $F$ is $C^{k-3}$ conjugate to a linear automorphism.

Proof. Item 1, resp. 3, follows from Corollary 3.9 and Theorem 2.17 (Theorem 3.4/Corollary 3.5 in [HuKa]), resp. Corollary 3.6 of Hurder-Katok [HuKa]. Besides, Item 2 follows from Item 1 and Theorem 2.18 (Théorème 4.6 in Ghys [G2]). \hfill $\Box$
3.3. From smooth orbit equivalence to smooth flow conjugacy. In this subsection, as in Corollary 3.10, let \( k \geq 5 \), and let \( \Phi \) be a \( C^k \) Anosov flow on some 3-dimensional Riemannian manifold \( M \) which preserves a smooth volume \( \mu \).

The following result explains how we can upgrade the smooth equivalence obtained in Corollary 3.10 to a smooth flow conjugacy.

**Proposition 3.11.** If the MME of \( \Phi \) is equal to the volume measure \( \mu \), then for any \( \varepsilon > 0 \), \( \Phi \) is \( C^{k-\varepsilon} \) conjugate to an algebraic flow.

**Proof.** Since the MME is equal to the volume measure \( \mu \), by Corollary 3.10, we know that \( W^s_\Phi \) and \( W^u_\Phi \) are \( C^{k-3} \) foliations, and the flow \( \Phi \) is orbit equivalent to an algebraic flow \( \Psi \) through a \( C^k \) map \( \mathcal{H} \). Up to a linear time change, without loss of generality, we can assume that the topological entropies of \( \Phi \), \( \Psi \) coincide, i.e., \( h_{\text{top}}(\Phi) = h_{\text{top}}(\Psi) = h > 0 \). Moreover, up to a \( C^k \) conjugacy, the flow \( \Phi \) can be seen as a reparametrization of \( \Psi \), the two flows induce the same Poincaré map on \( S \).

Let \( x \in M \) be a point in some periodic orbit \( \mathcal{O} \) of \( \Phi \), of period \( \mathcal{L}_\Phi(\mathcal{O}) = \mathcal{L}_\Phi(x) > 0 \). The orbit \( \mathcal{O} \) is also periodic for \( \Psi \), of period \( \mathcal{L}_\Psi(\mathcal{O}) = \mathcal{L}_\Psi(x) > 0 \). As the MME is equal to the volume measure \( \mu \), Proposition 3.1 yields

\[
J^u_{\Phi,x}(\mathcal{L}_\Phi(x)) = e^{h\mathcal{L}_\Phi(x)},
\]

where \( J^u_{\Phi,x}(\mathcal{L}_\Phi(x)) > 1 \) is the unstable Jacobian of \( \Phi \) at \( x \).

Similarly, for the algebraic flow \( \Psi \), we have

\[
J^u_{\Psi,x}(\mathcal{L}_\Psi(x)) = e^{h\mathcal{L}_\Psi(x)}.
\]

Let us take a smooth section \( S_x \) transverse to the flows \( \Phi, \Psi \) at \( x \). As \( \Phi \) is a smooth reparametrization of \( \Psi \), the two flows induce the same Poincaré map on \( S_x \), which we denote by \( \mathcal{F} \). When \( \mathcal{F} \) is seen as the Poincaré map of \( \Phi \), resp. \( \Psi \), the eigenvalues of its differential \( D\mathcal{F}_x \) (which are independent of the choice of the point \( x \) and of the transverse section at \( x \)) are equal to \( (J^u_{\Phi,x}(\mathcal{L}_\Phi(x)))^{\pm 1} \), resp. \( (J^u_{\Psi,x}(\mathcal{L}_\Psi(x)))^{-1} \), hence \( J^u_{\Phi,x}(\mathcal{L}_\Phi(x)) = J^u_{\Psi,x}(\mathcal{L}_\Psi(x)) \). Together with (3.6) and (3.7), we conclude that for any periodic orbit \( \mathcal{O} \), the associated periods for \( \Phi \) and \( \Psi \) are equal, i.e.,

\[
\mathcal{L}_\Phi(\mathcal{O}) = \mathcal{L}_\Psi(\mathcal{O}).
\]

Based on (3.8), we can produce a continuous flow conjugacy following a classical “synchronization” procedure, which we now recall.

Let us denote by \( X_\Phi \cdot \mathcal{H} \) the derivative of \( \mathcal{H} \) with respect to the flow vector field \( X_\Phi \); then for any \( x \in M \), it holds

\[
X_\Phi \cdot \mathcal{H}(x) = w_\mathcal{H}(x)X_\Psi(\mathcal{H}(x)),
\]

for some function \( w_\mathcal{H} : M \to \mathbb{R} \) which measures the “speed” of \( \mathcal{H} \) along the flow direction. By (3.8), the function \( w_\mathcal{H} - 1 \) integrates to 0 over all periodic orbits. By Livsic’s theorem (see [HaKa], Subsection 9.2), we deduce that there exists a continuous function \( u : M \to \mathbb{R} \) differentiable along the direction of the flow \( \Phi \) such that \( w_\mathcal{H} - 1 = X_\Phi \cdot u \). Now, let \( \mathcal{H}_0 : x \mapsto \Psi^{-u(x)} \circ \mathcal{H}(x) \). Given any \( x \in M \), we compute

\[
w_{\mathcal{H}_0}(x)X_\Psi(\mathcal{H}_0(x)) = X_\Phi \cdot (\Psi^{-u(x)} \circ \mathcal{H})(x)
= (w_\mathcal{H}(x) - X_\Phi \cdot u(x))X_\Psi(\Psi^{-u(x)} \circ \mathcal{H}(x)) = X_\Psi(\mathcal{H}_0(x)),
\]
i.e., \( w_{\mathcal{H}_0} \equiv 1 \). It follows that the homeomorphism \( \mathcal{H}_0 \) conjugates the flows \( \Phi \) and \( \Psi \):

\[
\mathcal{H}_0 \circ \Phi^t = \Psi^t \circ \mathcal{H}_0, \quad \forall t \in \mathbb{R}.
\]

Besides, the Lyapunov exponents of corresponding periodic orbits of \( \Phi \) and \( \Psi \) coincide (by Proposition 3.1, they are all equal to \( h_{\text{top}}(\Phi) = h_{\text{top}}(\Psi) = h \)). We conclude from a rigidity result of de la Llave (Theorem 1.1 in [dlL], see also [dlLM] where the \( C^\infty \) case was considered) that the conjugacy \( \mathcal{H}_0 \) is in fact \( C^k - \varepsilon \), for any \( \varepsilon > 0 \). □

Let us now conclude the proof of Theorem A. Given \( k \geq 5 \) and a \( C^k \) Anosov flow \( \Phi \) on some 3-manifold preserving a smooth volume measure \( \mu \), if the MME of \( \Phi \) is equal to \( \mu \), then Proposition 3.11 says that \( \Phi \) is \( C^k - \varepsilon \) conjugate to an algebraic flow, for any \( \varepsilon > 0 \). Conversely, assume that \( \Phi \) is a volume-preserving Anosov flow on some 3-manifold that is conjugate to an algebraic flow \( \Psi \) through a smooth map \( \mathcal{H} \). As the MME of \( \Psi \) coincides with the SRB measure, and the smooth conjugacy \( \mathcal{H} \) takes the MME, resp. the SRB of \( \Phi \) to the MME, resp. the SRB of \( \Psi \), we conclude that the MME of \( \Phi \) coincides with the volume measure, as desired. □

### 3.4. Entropy Flexibility

Theorem A has shown that for an Anosov flow \( \Phi \) on some 3-manifold preserving a smooth volume \( \mu \), \( h_{\text{top}}(\Phi) = h_{\mu}(\Phi) \) if and only if \( \Phi \) is an algebraic flow up to smooth conjugacy. In particular, the topological entropy \( h_{\text{top}}(\Phi) \) and the measure-theoretic entropy \( h_{\mu}(\Phi) \) of the volume measure have to be the same for algebraic flows. It is then natural to ask: what about non-algebraic flows? Here we show that the numbers of the topological entropy \( h_{\text{top}}(\Phi) \) and the measure-theoretic entropy \( h_{\mu}(\Phi) \) of the volume measure for the suspension flows over Anosov diffeomorphisms are quite flexible for non-algebraic flows.

We normalize the total volume of the suspension space to 1 (equivalently, we normalize the integral of \( r \) with respect to Lebesgue to be 1), i.e., \( \int r \, d\mu = 1 \). One may also think of this as finding a canonical linear time change of an arbitrary flow, and is analogous to fixing the volume of a surface when considering geodesic flows. There are three natural restrictions on \( h_{\text{top}}(\Phi) \) and \( h_{\mu}(\Phi) \). The Pesin entropy formula and positivity of Lyapunov exponents imply that \( h_{\mu}(\Phi) > 0 \). Moreover, the Variational Principle implies

\[
\begin{align*}
\frac{\int r \, d\mu}{\int r \, df} &= h_{\mu}(f) \leq h_{\text{top}}(f) := h.
\end{align*}
\]

Finally, the Abramov formula gives

\[
\begin{align*}
h_{\mu}(\Phi) &= \frac{\int r \, d\mu}{\int r \, df} = h_{\mu}(f) \leq h_{\text{top}}(f) := h.
\end{align*}
\]

Here we denote by \( h \) the topological entropy of the torus automorphism with the same homotopy type as \( f \). Since any Anosov diffeomorphisms in the same homotopy type are conjugated with each other [Fr], we have \( h = h_{\text{top}}(g) \), for any \( g \) in the same homotopy type as \( f \).

In this section, we shall prove Theorem D which says that the pair of values of entropy under the three natural restrictions mentioned above can all be achieved. Let \( A \in \text{SL}(2, \mathbb{Z}) \) be a hyperbolic matrix whose induced torus automorphism has topological entropy \( h \). Let \( \mu \) be the volume measure on \( \mathbb{T}^2 \). Then for any \( c_{\text{top}} > c_{\mu} > 0 \) such that \( c_{\mu} \leq h \), we shall find a volume-preserving Anosov diffeomorphism \( f: \mathbb{T}^2 \to \mathbb{T}^2 \) homotopic to \( A \) and a \( C^\infty \) function \( r: \mathbb{T}^2 \to \mathbb{R}^+ \) with integral 1 with respect to the volume measure such that if \( \Phi \) is the suspension flow induced by \( f \) and \( r \), \( h_{\text{top}}(\Phi) = c_{\text{top}} \) and \( h_{\mu}(\Phi) = c_{\mu} \).
The figure to the right shows the content of Theorem D, where the horizontal axis is $h_\mu$ and the vertical axis is $h_{\text{top}}$. The dashed area can be achieved by some suspension flow. The corner point represents the unique flow up to $C^\infty$ conjugacy, namely the algebraic flow. The boundaries are not achievable, with the exception of the right boundary. If we relax the regularity to $C^{1+\alpha}$ the bottom boundary is achievable.

To prove Theorem D, we shall use the following lemma, which follows immediately from the variational principle and Abramov formula.

**Lemma 3.12** ([KKW], Theorem 2). Suppose that $f: M \to M$ is an Anosov diffeomorphism of a smooth manifold, and $\Phi_r$ is the suspension flow of $f$ with $C^\infty$ roof function $r$. Then $r \mapsto h_{\text{top}}(\Phi_r)$ is continuous.

Now we are ready to give the proof of Theorem D.

**Proof of Theorem D.** We first realize $c_{\text{top}} \geq h$. By [HJJ], for any $h \geq c_\mu > 0$, there exists a volume-preserving $f: \mathbb{T}^2 \to \mathbb{T}^2$ of homotopy type $A$ such that $h_\mu(f) = c_\mu$. Taking the roof function $r \equiv 1$ gives the case of $c_{\text{top}} = h$. To produce more topological entropy (i.e., fill in region II), we follow the approach of [EK]. Since we may homotope the roof function to a constant, it suffices to show that $h_{\text{top}}(\Phi_r)$ can be made arbitrarily large while keeping $\int r = 1$, by Lemma 3.12. Given $\varepsilon, \delta > 0$, let $r: \mathbb{R}^2 \to \mathbb{R}^+$ be a $C^\infty$ function satisfying $r \geq \delta$, $\int r \, d\mu = 1$ and $r|_{\mathbb{T}^2 \setminus B_\varepsilon(0)} \equiv \delta$.

It is clear that such functions exist. Let $\sigma: \Sigma_0 \to \Sigma_0$ be a Markov shift coding $f$, with coding map $\pi: \Sigma_0 \to \mathbb{T}^2$. By choosing $\varepsilon$ sufficiently small, and a sufficient refinement of a Markov partition for $f$, we can find a subshift $\Sigma \subset \Sigma_0$ such that $\pi(\Sigma) \cap B_\varepsilon(0) = \emptyset$ and $h_{\text{top}}(\sigma|_{\Sigma}) > 0$. This can be constructed easily symbolically by increasing the “memory” of $\Sigma_0$ and disallowing the blocks containing 0, but a more geometric construction can be found in [K2, Corollary 4.3]. Hence the topological entropy of the flow is at least the topological entropy of the flow restricted to the suspension of this subshift. Since $r$ is identically $\delta$ on $\pi(\Sigma)$, $h_{\text{top}}(\Phi_r) \geq h_{\text{top}}(\sigma|_{\Sigma})/\delta$. Since $\delta$ can be arbitrarily small, we get the result.

Now we consider the case where $c_\mu < c_{\text{top}} < h$ (i.e., region I). We start by again taking an Anosov diffeomorphism $f: \mathbb{T}^2 \to \mathbb{T}^2$ such that $h_\mu(f) = c_\mu$. If we choose the $C^{1+\alpha}$ roof function $x \mapsto \|Df_x|_{E^u}\|$ (normalized to have integral one), we obtain a flow such that $h_{\text{top}}(\Phi_r) = h_\mu(f) = c_\mu$. By perturbing $r$ to a $C^\infty$ roof function $C^1$-close to $r$, we can get a $C^\infty$ roof function with topological entropy arbitrarily close to $c_\mu$. Then taking a linear homotopy of the roof function to a constant gives all intermediate values. \hfill $\Box$

4. Some results towards entropy rigidity for dispersing billiards
4.1. Preliminaries on dispersing billiards. In the following, we consider dispersing billiards of two types:

1. open dispersing billiard tables \( \mathcal{D} := \mathbb{R}^2 \setminus \bigcup_{i=1}^{m} \mathcal{O}_i \), for some integer \( m \geq 3 \), where \( \mathcal{O}_1, \ldots, \mathcal{O}_m \) are pairwise disjoint closed domains with \( C^\infty \) boundary having strictly positive curvature (in particular, they are strictly convex) and satisfying the non-eclipse condition, i.e., that the convex hull of any two \( \mathcal{O}_i, \mathcal{O}_j, i \neq j \), is disjoint from the remaining \( m-2 \) domains;

2. Sinai billiard tables \( \mathcal{D} \subset \mathbb{T}^2 \) given by \( \mathcal{D} = \mathbb{T}^2 \setminus \bigcup_{i=1}^{m} \mathcal{O}_i \), for some integer \( m \geq 1 \), where \( \mathcal{O}_1, \ldots, \mathcal{O}_m \) are pairwise disjoint closed obstacles with \( C^\infty \) boundary having strictly positive curvature.

In either case, we refer to each of the \( \mathcal{O}_i \)'s as obstacle or scatterer. We let \( \ell_i := |\partial \mathcal{O}_i| \) be the corresponding lengths, and set \( T_i := \mathbb{R}/\ell_i \mathbb{Z} \). We also denote by \( |\partial \mathcal{D}| := \sum_{i=1}^{m} \ell_i \) the total perimeter of the boundary of \( \mathcal{D} \).

For a fixed integer \( m \geq 1 \), the set of all billiard tables of type (1) or (2) will be denoted by \( \mathcal{B}^{(1)}(m), \mathcal{B}^{(2)}(m) \) respectively. Let \( i \in \{1, 2\} \) and let \( \mathcal{D} \in \mathcal{B}^{(i)}(m) \). We denote by \( \mathcal{O}_1, \ldots, \mathcal{O}_m \) the collision, and we introduce the collision space

\[ \mathcal{M} = \bigcup_i \mathcal{M}_i, \quad \mathcal{M}_i = \{(q, v), q \in \partial \mathcal{O}_i, v \in \mathbb{R}^2, ||v|| = 1, \langle v, n \rangle \geq 0\}, \]

where \( n \) is the unit normal vector to \( \partial \mathcal{O}_i \) pointing inside \( \mathcal{D} \). For each \( x = (q, v) \in \mathcal{M} \), \( q \) is associated with the arclength parameter \( s \in [0, \ell_i] \) for some \( i \in \{1, \ldots, m\} \), and we let \( \phi \in [-\frac{\pi}{2}, \frac{\pi}{2}] \) be the oriented angle between \( n \) and \( v \). In other words, each \( \mathcal{M}_i \) can be seen as a cylinder \( \mathbb{T}_i \times [-\frac{\pi}{2}, \frac{\pi}{2}] \) endowed with coordinates \( x = (s, \phi) \).

Set \( \Omega := \{(q, v) \in \mathcal{D} \times \mathbb{S}^1\} \). The billiard flow \( \Phi = (\Phi_t)_{t \in \mathbb{R}} \) on \( \Omega \) is the motion of a point particle traveling in \( \mathcal{D} \) at unit speed and undergoing elastic reflections at the boundary of the scatterers (by definition, at a grazing collision, the reflection does not change the direction of the particle). A key feature is that, although the billiard flow is continuous if one identifies outgoing and incoming angles, the tangential collisions give rise to singularities in the derivative [CM]. Let

\[ \mathcal{F} = \mathcal{F}(\mathcal{D}) : \mathcal{M} \rightarrow \mathcal{M}, \quad x \mapsto \Phi^T_x + \tau(x) \]

be the associated billiard map, where \( \tau: \mathcal{M} \rightarrow \mathbb{R}_+ \cup \{+\infty\} \) is the first return time.

A periodic orbit is called regular if it does not experience grazing collisions. For any regular periodic orbit \( \sigma = (x_1, \ldots, x_p) \) of period \( p \geq 2 \), we have \( D_{x_j} \mathcal{F}^p \in \text{SL}(2, \mathbb{R}) \), for \( j \in \{1, \ldots, p\} \).\(^5\) Due to the strict convexity of the obstacles, \( D_{x_j} \mathcal{F}^p \) is hyperbolic, and we let \( 0 < \lambda < 1 < \lambda^{-1} \) be its eigenvalues. The Lyapunov exponent of this orbit is defined as

\[ \text{LE}(\sigma) := -\frac{1}{p} \log \lambda > 0. \]

4.2. Open dispersing billiards. We consider a table \( \mathcal{D} = \mathbb{R}^2 \setminus \bigcup_{i=1}^{m} \mathcal{O}_i \in \mathcal{B}^{(1)}(m) \), for some integer \( m \geq 3 \). The nonwandering set \( \Omega \) is homeomorphic to a Cantor set. The restriction of the billiard map \( \mathcal{F} \) to \( \Omega \) is conjugated to a subshift of finite type associated with the transition matrix \( (1 - \delta_{ij})_{1 \leq i, j \leq m} \), where \( \delta_{ij} = 1 \) if \( i = j \), and \( \delta_{ij} = 0 \) otherwise. In other words, any word \( \langle s_j \rangle_j \in \{1, \ldots, m\}^\mathbb{Z} \) such that \( s_{j+1} \neq s_j \) for all \( j \in \mathbb{Z} \) can be realized by a unique orbit, where the different

---

\(^5\)Recall that for \( x = (s, \phi) \in \mathcal{M} \) and \( x' = (s', \phi') := \mathcal{F}(s, \phi) \), we have \( \det D_x \mathcal{F} = \frac{\cos \phi}{\cos \phi'} \). Thus, for any periodic orbit \( \mathcal{O} = (x_1, x_2, \ldots, x_p) \) of period \( p \geq 2 \), we have \( \det D_{x_j} \mathcal{F}^p = 1 \), for \( j \in \{1, \ldots, p\} \).
symbols represent the obstacles on which the successive collisions happen. Such a word is called *admissible*. In particular, any periodic orbit of period $p$ (observe that necessarily $p \geq 2$) can be labeled by a periodic admissible word $\sigma^\infty := \ldots \sigma \sigma \sigma \ldots$, for some finite word $\sigma = (\sigma_1 \sigma_2 \ldots \sigma_p) \in \{1, \ldots, m\}^p$. For more regarding open dispersing billiards, we refer the reader to [BDKL].

The symbolic coding gives a convenient way to identify homoclinic orbits. Indeed, let us consider any periodic point $x \leftarrow \ldots \sigma_p | \sigma_1 \sigma_2 \ldots \sigma_p | \sigma_1 \sigma_2 \ldots \sigma_p | \sigma_1 | \sigma_1 \ldots \leftarrow \uparrow$ for some finite word $\sigma = (\sigma_1 \sigma_2 \ldots \sigma_p) \in \{1, \ldots, m\}^p$, $p \geq 2$.

Let us take a word $\tau = (\tau_1 \tau_2 \ldots \tau_p) \in \{1, \ldots, m\}^p$ such that the following word is admissible and defines a point $x_\infty$ homoclinic to $x$:

$$x_\infty \leftarrow \ldots \sigma_p | \sigma_1 \sigma_2 \ldots \sigma_p | \tau_1 \ldots \tau_p | \sigma_1 \sigma_2 \ldots \sigma_p | \sigma_1 \sigma_2 \ldots \sigma_p | \sigma_1 \ldots \sigma_1 \ldots \leftarrow \uparrow$$

In particular, the dynamics is Axiom A, and the nonwandering set $\Omega$ is reduced to one basic set. Moreover, orbits in $\Omega$ are far from the singularities; in particular, every periodic orbit is regular. By Proposition 2.12, we know that the restriction $\Phi|_\Omega$ has a unique SRB measure and a unique MME. Moreover, by Proposition 3.1, equality of the SRB measure and of the MME forces the Lyapunov exponents of periodic points to be equal, and arguing as in Subsection 3.2, thanks to Corollary 3.8, we conclude:

**Theorem 4.1.** If the MME is equal to the SRB measure, then the first Birkhoff invariant of each periodic orbit vanishes, i.e., $a_1(\sigma) = 0$, for any periodic orbit $\sigma$.

### 4.3. Sinai billiards

We consider a Sinai billiard table $\mathcal{D} = \mathbb{T}^2 \setminus \bigcup_{i=1}^{m} O_i \in B^{(2)}(m)$, for some integer $m \geq 1$. We assume the boundary of each scatterer $O_1, \ldots, O_m$ is of class $C^\infty$, and that $\mathcal{D}$ has *finite horizon*, i.e., that no trajectory makes only tangential collisions. As previously, we denote by $\mathcal{F} = \mathcal{F}(\mathcal{D})$: $(s, \varphi) \mapsto (s', \varphi')$ the billiard map. It is a local $C^\infty$ diffeomorphism. Let us also recall that $\mathcal{F}$ preserves a smooth invariant SRB probability measure $\mu = \frac{1}{2|\partial \mathcal{D}|} \cos \varphi \, dsd\varphi$ with respect to which the dynamics is ergodic, K-mixing, and Bernoulli.

Due to the existence of grazing collisions, the billiard map $\mathcal{F}$ has singularities, yet in [BD], Baladi and Demers are able to define a suitable notion of topological entropy $h_*$ for $\mathcal{F}$. They need some quantitative control on the recurrence to the set of singularities, which we recall now. Let $\varphi_0 \in \mathbb{R}$ be a number close to $\pi/2$, and let $n_0 \in \mathbb{N}$ be some integer; a collision is called $\varphi_0$-grazing if the absolute value of its angle with the normal is larger than $\varphi_0$. Let $s_0 = s_0(\varphi_0, n_0) \in (0, 1]$ be the smallest number such that

any orbit of length $n_0$ has at most $s_0 n_0$ collisions which are $\varphi_0$ grazing.

The condition that the authors require in [BD] is that for a certain choice of $\varphi_0, n_0$, it holds

$$h_* > s_0 \log 2.$$  

In the following, we assume that (4.1) holds. Let us recall some of the main results of the work [BD]:

---

6Indeed, thanks to the finite horizon assumption, we can choose $\varphi_0, n_0$ such that $s_0 < 1$. 
Theorem 4.2 (Theorem 2.4, Proposition 7.13 in [BD]). The billiard map $\mathcal{F}$ admits a unique invariant Borel probability measure $\mu_*$ of maximal entropy, i.e., $h_{\mu_*}(\mathcal{F}) = h_*$. Moreover, if $\mu_*$ is equal to the SRB measure, i.e., $\mu_* = \mu$, then all the regular periodic orbits have the same Lyapunov exponent, i.e.,

$$\text{LE}(\sigma) = h_* , \quad \text{for any regular periodic orbit } \sigma.$$

Let us note that (4.2) is the exact analogue of the result obtained in Proposition 3.1 in the case of an Axiom A flow restricted to some basic set.

Let $x$ be a point in a regular periodic orbit for the billiard map $\mathcal{F}$; replacing $\mathcal{F}$ with some iterate, without loss of generality, we may assume that $x$ is a saddle fixed point, i.e., $\mathcal{F}(x) = x$, and we denote by $0 < \lambda < 1 < \lambda^{-1}$ the eigenvalues of $D\mathcal{F}_x$. Let us assume that there exists a homoclinic point $x_\infty \in W^u_\mathcal{F}(x) \cap W^s_\mathcal{F}(x)$. As in Subsection 3.2, we let $S_0 \subset S$ be a small neighbourhood of the periodic point $x$ encoded by the symbol 0, and let $S_1 \subset S$ be a small neighbourhood of the homoclinic point $x_\infty$ encoded by the symbol 1, so that the symbolic coding associated to $x_\infty$ is

$$x_\infty \leftrightarrow \ldots 0001000\ldots$$

We select the sequence $(h_n)_{n \geq 1}$ of periodic orbits in the horseshoe associated to the homoclinic intersection, whose symbolic coding is given by

$$h_n \leftrightarrow \ldots |0 \ldots 01|0 \ldots 01|0 \ldots 01|\ldots$$

For each $n \geq 1$, $h_n$ has period $n + 2$. We denote by $x_n^1$, resp. $x_n^2$, the coordinates of its periodic approximation in $h_n$, encoded by the symbolic sequence

$$x_n^1 \leftrightarrow \ldots |0 \ldots 001|0 \ldots 01|\ldots , \quad \text{resp. } x_n^2 \leftrightarrow \ldots |0 \ldots 01|0 \ldots 01|\ldots$$

As recalled in Subsection 2.3, if $S_0$ is taken sufficiently small, there exists a $C^\infty$ volume-preserving change of coordinates $R_0: S_0 \to \mathbb{R}^2$ which conjugates $\mathcal{F}$ to its Birkhoff Normal Form $N = R \circ \mathcal{F} \circ R^{-1}$:

$$N = N_\Delta: (\xi, \eta) \mapsto (\Delta(\xi \eta) \cdot \xi, \Delta(\xi \eta)^{-1} \cdot \eta),$$

for some function $\Delta: z \mapsto \sum_{k=0}^{+\infty} a_k z^k$, with $a_0 = \lambda \neq 0$. Moreover, by Lemma 3.2, the conjugacy $R$ can be chosen in such a way that for all $n \geq 1$,

$$R(x_n^1) = (\eta_n, \xi_n) \in \Gamma_1 , \quad R(x_n^2) = (\xi_n, \eta_n) \in \Gamma_2,$$

where $\Gamma_1 = \{ (\eta, \gamma(\eta)) : |\eta| \ll 1 \}$, $\Gamma_2 = \{ (\gamma(\eta), \eta) : |\eta| \ll 1 \}$, are two smooth arcs which are mirror images of each other under the reflection with respect to the first bissectrix $\{ \xi = \eta \}$. We denote by $\sum_{k=0}^{+\infty} \gamma_k \eta^k$ the jet of $\gamma$ at 0. When $n \to \infty$, we have $(\eta_n, \xi_n) \to (0, \xi_\infty)$, with $\xi_\infty = \gamma_0 \neq 0$.

Let $G = R \circ \mathcal{F}^2 \circ R^{-1}$ be the gluing map from a neighbourhood of $(0, \xi_\infty)$ to a neighbourhood of $(\xi_\infty, 0)$. For $|\eta|$ sufficiently small, according to formula (4.4) in [DKL], it holds

$$D_{(\eta, \gamma(\eta))}G = \begin{bmatrix} \gamma'(\eta)(2 - \gamma'(\eta)g(\eta)) & \gamma'(\eta)g(\eta) - 1 \\ 1 - \gamma'(\eta)g(\eta) & g(\eta) \end{bmatrix},$$

for some $C^\infty$ function $g: \mathbb{R} \to \mathbb{R}$ whose jet at 0 is denoted by $\sum_{k=0}^{+\infty} g_k \eta^k$.

For any integer $n \geq 1$, set $\zeta_n := \xi_n \eta_n$, and

$$\Delta_n := \Delta(\zeta_n) , \quad \Delta'_n := \Delta'(\zeta_n) \zeta_n.$$
As an immediate consequence of (4.3) and (4.4), we have

\[ \eta_n = \Delta_n^+ \xi_n = \Delta_n^\gamma(\eta_n). \]

For any integer \( k \geq 0 \), we introduce scaled coefficients

\[ \bar{a}_k := \lambda^{-k} a_k \xi_\infty^k, \quad \bar{\gamma}_k := \gamma_k \xi_\infty^k, \quad \text{and} \quad \bar{g}_k := g_k \xi_\infty^k, \]

with \( a_0 = \lambda \) and \( \gamma_0 = \xi_\infty \). Note that \( \bar{a}_0 = \bar{\gamma}_0 = 1 \) and \( \bar{g}_0 = g_0 \neq 0 \) (see (3.5)).

In the following, for any integer \( n \geq n_0 \), we also let

\[ \bar{\eta}_n := (\xi_\infty \lambda^n)^{-1} \eta_n. \]

Note that (4.6) can be rewritten as

\[ \bar{\eta}_n = \bar{\Delta}(\lambda^n \bar{\eta}_n \bar{\gamma}(\lambda^n \bar{\eta}_n)) \bar{\gamma}(\lambda^n \bar{\eta}_n), \]

where the jets of \( \bar{\Delta} \) and \( \bar{\gamma} \) are respectively

\[ \bar{\Delta}(z) = 1 + \sum_{k=1}^{+\infty} \bar{a}_k z^k, \quad \text{and} \quad \bar{\gamma}(z) = 1 + \sum_{k=1}^{+\infty} \bar{\gamma}_k z^k. \]

Following [DKL], the Lyapunov exponents of the periodic orbits \((h_n)_{n \geq 1}\) can be expressed in terms of the new coordinates; the triangular structure of the following expansion follows from (4.9).

**Lemma 4.3** (Lemma 4.8 and Lemma 4.20 in [DKL]). As \( n \to +\infty \), the asymptotics of the Lyapunov exponent of the periodic orbit \( h_n \) is

\[ 2 \lambda^n \cosh((n + 2)\text{LE}(h_n)) = I_n + \lambda^n \Pi_n + \lambda^{2n} \Pi_n, \]

where

\[ I_n := \lambda^n \Delta_n^{-n}(1 - n \Delta_n \Delta_n^{-1}) g(\eta_n), \]

\[ \Pi_n := 2n \Delta_n \Delta_n^{-1}(1 - \gamma'(\eta_n) g(\eta_n)), \]

\[ \Pi_n := -2n \Delta_n^{-n}(1 + n \Delta_n \Delta_n^{-1}) \gamma'(\eta_n)(2 - \gamma'(\eta_n) g(\eta_n)). \]

Moreover, there exists a sequence of real numbers \((L_{q,p})_{p=0,\ldots,+\infty}^{q=0,\ldots} \) such that

\[ 2 \lambda^n \cosh((n + 2)\text{LE}(h_n)) = \sum_{p=0}^{+\infty} \sum_{q=0}^{p} L_{q,p} \lambda^{q+p}. \]

Let us now assume that the measure of maximal entropy \( \mu_* \) is equal to the SRB measure \( \mu \). In particular, by Theorem 4.2, for any integer \( n \geq 1 \), we have

\[ \text{LE}(h_n) = h_* \]

By (4.11), we deduce that

\[ L_{q,p} = 0, \quad \forall (q, p) \neq (0, 0), (0, 2), \]

while \( L_{0,0} = \lambda^{-2} \) and \( L_{0,2} = \lambda^2 \).

As a consequence, we are able to conclude the proof of Theorem E.\(^7\)

**Corollary 4.4.** If \( \mu_* = \mu \), then the Birkhoff Normal Form \( N \) is linear, i.e.,

\[ a_k = 0, \quad \forall k \geq 1. \]

\(^7\)A similar result also holds in the case of open dispersing billiards.
Proof. Assume by contradiction that $N$ is not linear, and let $k_0 \geq 1$ be smallest such that $a_{k_0} \neq 0$. By (4.9), we have
\[
\eta_n = \xi_\infty \lambda^n + O(n \lambda^{2n}),
\]
and as $z \Delta'(z) = k_0 a_{k_0} z^{k_0} + O(z^{k_0+1})$, we also get
\[
(4.13) \quad \Delta'_n = \zeta_n \Delta' = k_0 a_{k_0} \xi_\infty^2 \lambda^{2k_0} + O(n \lambda^{n(k_0+1)}).
\]
For any series of the form
\[
(T) \quad \sum_{k,l \geq 0} \alpha_{k,l} n^k \lambda^{nl}, \text{ for some coefficients } (\alpha_{k,l})_{k,l \geq 0},
\]
we let
\[
\mathbb{P}_1 \left( \sum_{k,l \geq 0} \alpha_{k,l} n^k \lambda^{nl} \right) := \sum_{l \geq 0} \alpha_{1,l} n^{nl}.
\]
It follows from (4.9) that $\eta_n$ has an expansion of the form (T) (see [DKL] for more details), and
\[
\mathbb{P}_1(\eta_n) = \xi_\infty a_{k_0} n \lambda^{n(k_0+1)} + \text{H.O.T.}
\]
Similarly, as $\Delta_n^{-n} = (\Delta(\zeta_n))^{-n}$, we obtain
\[
\mathbb{P}_1(\Delta_n^{-n}) = -a_{k_0} n \lambda^{n(k_0-1)} + \text{H.O.T.}
\]
Besides, by (4.13), we have
\[
\mathbb{P}_1(n \Delta'_n \Delta_n^{-1}) = k_0 a_{k_0} n \lambda^{n(k_0-1)} + \text{H.O.T.}
\]
If we look at (4.10), as $g_0 \neq 0$ (by (3.5)), and because of the different weights of $I_n$, $\Pi_n$ and $\Pi_3$ in (4.10), we obtain
\[
\begin{align*}
\mathbb{P}_1 \left( 2 \lambda^n \cosh((n + 2) \Lambda(h_n)) \right) &= \mathbb{P}_1(I_n) + \text{H.O.T.} \\
&= \lambda^n \left( \mathbb{P}_1(\Delta_n^{-n}) \cdot 1 \cdot g_0 - \lambda^{-n} \cdot \mathbb{P}_1(n \Delta'_n \Delta_n^{-1}) \cdot g_0 + \lambda^{-n} \cdot 1 \cdot \mathbb{P}_1(g_1 \eta_n) \right) + \text{H.O.T.} \\
&= \lambda^n \left( -g_0 a_{k_0} n \lambda^{n(k_0-1)} - g_0 k_0 a_{k_0} n \lambda^{n(k_0-1)} \right) + \text{H.O.T.} \\
&= -g_0 (k_0 + 1) a_{k_0} n \lambda^{n(k_0)} + \text{H.O.T.}
\end{align*}
\]
As a result, we deduce that
\[
L_{1,k_0} = -g_0 (k_0 + 1) a_{k_0} \neq 0,
\]
which contradicts (4.12). \qed

Remark 4.5. Note that when the conclusion of Corollary 4.4 is true, some of the above expressions can be simplified. Equation (4.6) becomes
\[
\eta_n = \lambda^n \gamma' \eta_n,
\]
so that $\eta_n$ can be expressed only in terms of the jet of $\gamma$. Besides, (4.10) becomes
\[
\lambda^{-n-2} + \lambda^{n+2} = \lambda^{-n} g(\eta_n) + \lambda^n \gamma' \eta_n (2 - \gamma'(\eta_n) g(\eta_n)).
\]
In particular, the jets of $\gamma$ and $g$ are strongly correlated.

We note the following is the natural question in view of these results, and the fact that the Birkhoff Normal Form is determined locally for periodic orbits:
Question 2. Do there exist curves \( \gamma, \delta : [-\varepsilon, \varepsilon] \to \mathbb{R} \) such that \( \gamma(0) = 0, \delta(0) = 1, \gamma'(0) = \delta'(0) = 0 \) and \( \gamma''(0) < 0 < \delta''(0) \) such that the 2-periodic orbit of the local billiard between the graphs of \( \gamma \) and \( \delta \) has linear Birkhoff Normal Form?

A solution to this question would give a candidate for the local behavior of a “homogeneous” hyperbolic billiard. A negative answer would suggest that no such billiard exists.

Remark 4.6. Given a periodic orbit with Birkhoff Normal Form \( N \) and Birkhoff invariants \((a_k)_{k \geq 0}, |a_0| = | \lambda | \in (0, 1) \), for \((\xi, \eta)\) close to \((0, 0)\), we have the expansion

\[
DN(\xi, \eta) = \begin{bmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{bmatrix} - \lambda^{-1} a_1 \begin{bmatrix} -2\lambda \xi \eta & -\lambda \xi^2 \\ \lambda^{-1} \eta^2 & 2\lambda^{-1} \xi \eta \end{bmatrix} + \text{H.O.T.},
\]

where for \( \xi \eta \neq 0 \), the determinant \(-3\lambda^2 \eta^2\) of the second matrix is non-zero. In particular, \( a_1 \) vanishes if and only if the quadratic part in the expansion of \( DN \) is degenerate.

In the case of a 2-periodic orbit, one possibility to show that \( a_1 \neq 0 \) would thus be to compute the quadratic part in the expansion of \( DF^2 \) and show that it is non-degenerate (possibly due to the strict convexity of the obstacles).

Appendix A. Bowen-Margulis measure

In this appendix, we assume that \( \Phi \) is a topologically mixing smooth Anosov flow on some compact 3-manifold \( M \). Let us recall that by a result of Plante [Pl], \( \Phi \) is topologically mixing if and only if \( E^s_\Phi \) and \( E^u_\Phi \) are not jointly integrable. As the measure of maximal entropy is unique, it is given by the construction introduced by Margulis, which we now recall. It is first done by constructing a family of measures \( \nu^{cu} \) and \( \nu^s \) defined on leaves of the unstable foliation \( W^u_\Phi \) and of the stable foliation \( W^s_\Phi \), respectively, such that:

\[
(\Phi^t)_* \nu^u = e^{ht} \nu^u, \quad (\Phi^t)_* \nu^s = e^{-ht} \nu^s,
\]

where \( h := h_{\text{top}}(\Phi) > 0 \) is the topological entropy of \( \Phi \). Moreover, \( \nu^u \) is invariant by holonomies along the leaves of \( W^u_\Phi \), while \( \nu^s \) is invariant by holonomies along the leaves of \( W^s_\Phi \). Notice that (A.1) allows \( \nu^u \) and \( \nu^s \) to be easily extended to measures \( \nu^{cu} \) and \( \nu^{cs} \) on leaves of the weak unstable foliation \( W^{cu}_\Phi \) and of the weak stable foliation \( W^{cs}_\Phi \), respectively.

The Bowen-Margulis measure \( \mu \) of \( \Phi \) on \( M \) is then constructed locally using the local product structure of the manifold. That is, at \( x \in M \), choose open neighbourhoods of \( U(x) \subset W^{cu}_\Phi(x) \) and \( V(x) \subset W^s_\Phi(x) \), so that there is a well-defined map \( \varphi : O(x) \to M \) which gives Hölder coordinates on the local product cube \( O(x) := U(x) \times V(x) \subset M \). Fix an arbitrary \( y \in U(x) \). For any open set \( \Omega \subset O(x) \), we let

\[
\mu(\Omega) := \int_{z \in V(x)} \nu^{cu}(U(x) \times \{z\} \cap \Omega) \, d\nu(y)(z),
\]

where for any \( \Omega' \subset V(x) \), we set \( \nu_y(\Omega') := \nu^s(\{y\} \times \Omega') \). By the invariance of \( \nu^s \) under weak unstable holonomies, the previous definition is independent of the choice of \( y \in U(x) \) and defines locally the Bowen-Margulis measure \( \mu = \nu^{cu} \times \nu^s \).
where \( \{ \text{foliation } W_q \} \) for almost every continuous with respect to the Lebesgue measure on the leaf \( W_0(x) \). Furthermore, the density \( e^{\psi} \) is Hölder continuous and smooth within the leaf \( W_0(x) \), and

\[
\psi(\Phi^t(y)) - \psi(y) + ht = \log J_y^u(t), \quad \forall y \in W_0(x),
\]

where \( J_y^u(t) \) is the Jacobian of the map \( D\Phi^t|_{E_y}(y): E_y(y) \to E_y(\Phi^t(y)) \).

**Proof.** Fix \( x \in M \) and choose a neighbourhood \( O(x) = U(x) \times V(x) \) with local product structure and let \( \varphi \) be coordinates on \( O(x) \) as described above. Fix a point \( p = \varphi(y, z) \in O(x) \). On the one hand, by the construction recalled previously, we have

\[
d\mu(p) = d\nu^{cu}(y) \otimes d\nu^s(z).
\]

On the other hand, the measure \( \mu \) has local product structure, hence there exists a positive Borel function \( \rho: U(x) \times V(x) \) such that

\[
d\mu(p) = \rho(y, z) d\mu_x^{cu}(y) \otimes d\mu_z^s(z),
\]

where \( \{ \mu_x^{cu} \}_{q \in O(x)} \), resp. \( \{ \mu_y^s \}_{q \in O(x)} \) is a a system of conditional measures of \( \mu \) for the foliation \( W_0^{cu} \), resp. \( W_0^s \). As the foliations \( W_0^{cu} \) and \( W_0^s \) are absolutely continuous, for almost every \( q \in O(x) \), the conditional measure \( \mu_q^{cu} \), resp. \( \mu_q^s \) is absolutely continuous with respect to the Lebesgue measure on the leaf \( W_0^{cu}(q) \), resp. \( W_0^s(q) \). If we fix \( z \in V(x) \), we deduce from (A.3)-(A.4) and the previous discussion that

\[
d\nu^{cu}(y) = e^{\psi(y)} dy,
\]

where \( dy \) denotes the Lebesgue measure on \( U(x) \subset W_0^s(x) \). Applying \( (\Phi^t)_* \), it follows from (A.1) and (A.5) that

\[
e^{ht} d\nu^{cu}(\Phi^t(y)) = e^{ht + \psi(\Phi^t(y))} dy = e^{\psi(y)}(\Phi^t)_* dy = e^{\psi(y)} J_y^u(t) dy,
\]

for some measurable function \( \psi: M \to \mathbb{R} \), where \( J_y^u(t) \) is the unstable Jacobian of \( D\Phi^t \) at \( y \). Thus, for almost every \( y \), it holds

\[
\psi(\Phi^t(y)) - \psi(y) + ht = \log J_y^u(t).
\]

In other words, \( \psi \) is a measurable transfer function making \( \log J^u \) cohomologous to a constant. By Livsic’s theorem, \( \psi \) coincides almost everywhere with a Hölder solution which is smooth along the unstable leaves and Hölder transversally. With the upgraded regularity, we define an a priori new family of conditionals along the unstable leaves at every point. By uniqueness of the family of measures satisfying (A.1) (up to multiplicative constant), these must coincide with \( \nu^{cu} \) up to fixed scalar. Therefore, \( \nu^{cu} \) is absolutely continuous with smooth density. \( \square \)

**Remark A.2.** By Proposition A.1, for any periodic point \( y \) of period \( L(y) > 0 \), taking \( t = L(y) \) in (A.2), we obtain another proof of Proposition 3.1 when \( \Phi \) is topologically mixing. Conversely, if (3.1) holds for any periodic orbit, then by Livsic’s theorem, the \( C^1 \) cocycle

\[
C: (y, t) \mapsto \log J_y^u(t) - ht
\]

over \( \Phi \) is a coboundary, and (A.2) follows.
