The Schwarzschild solution in a Kaluza-Klein theory with two times

J. Kociński and M. Wierzbicki
Faculty of Physics, Warsaw University of Technology
Koszykowa 75, 00-662 Warszawa, Poland

A new spherically-symmetric solution is determined in a noncompactified Kaluza-Klein theory in which a time character is ascribed to the fifth coordinate. This solution contains two independent parameters which are related with mass and electric charge. The solution exhibits a Schwarzschild radius and represents a generalization of the Schwarzschild solution in four dimensions. The parameter of the solution connected with the electric charge depends on the derivative of the fifth (second time) coordinate with respect to the ordinary time coordinate. It is shown that the perihelic motion in four-dimensional relativity has a counterpart in five dimensions in the perinucleic motion of a negatively-charged particle. If the quantization conditions of the older quantum theory are applied to that motion, an analogue of the fine-structure formula of atomic spectra is obtained.

I. INTRODUCTION

The idea of two times in a physical theory gained an impetus with the investigations of I. Bars and his coworkers [1, 2, 3, 4, 5]; two-times physics provides a new perspective for understanding the one-time dynamics from a higher-dimensional point of view. From a single action formula of two-time physics, with the application of gauge theory, diverse one-time dynamical systems can be obtained.

In general relativity the second time variable was introduced and discussed in the quality of a universal parametric “historical time” by Horwitz and Piron [6], or as its generalization by Burakovskiy and Horwitz [7].

In the Kaluza-Klein theory three objections were raised against the timelike signature of the fifth coordinate [8, 9, 10, 11]. (1) When in the five-dimensional action the integration over the fifth coordinate is performed, provided that all the derivatives with respect to $x_5$ are omitted and the cylinder condition is accepted, the Maxwell action comes out with an opposite sign to that of the Einstein action which is incorrect. (2) The existence of tachyons follows from the accepted cylinder condition. (3) There would appear closed time curves.

The problem of closed time curves in four-dimensional gravity was investigated in a series of papers of Friedman, Thorne and their coworkers [12, 13, 14]. A particular attention was paid to the question whether closed time curves violate the causality principle. The present answer does not seem to be conclusive in that respect. In the case of the five-dimensional gravity with two time variables an analogous investigation has not been undertaken. It is an open question whether the second objection is relevant in noncompactified Kaluza-Klein theories to which this paper refers. The first objection would be relevant in a noncompactified Kaluza-Klein theory if it were confirmed. The attitude towards a timelike signature of the fifth coordinate is less restrained in [15] where spacelike or timelike signature of the fifth coordinate is admitted depending on the physical problem in question.

In Section 2 we start from the line element which formally is identical with that of Chodos and Detweiler [16]. The difference consists in the spatial character of the fifth coordinate $x^5$ in [16] and the time character ascribed to this coordinate in the present case. We determine a static five-dimensional spherically-symmetric solution on the basis of the line element in which there are two time coordinates. This solution exhibits a Schwarzschild radius and represents a generalization of the four-dimensional Schwarzschild solution. The solution depends on four parameters of which two are independent and can be related with gravitational mass and electric charge. This is accomplished in Section 3 where we discuss the geodesic equation in a nearly flat space. From the geodesic equation there follows a linear relation between the ordinary time $t$ and the second time variable $u$. In Section 4 we solve the problem of the perinucleic motion of a negatively charged test particle (electron) moving in the field of the central positively charged mass. Including into the five-dimensional geometry the quantization conditions of the older quantum theory [17] we derive an analogue of Sommerfeld’s relativistic energy-level formula [17].

II. A SPHERICALLY-SYMMETRIC SOLUTION FOR A TWO-TIME LINE ELEMENT

We consider the line element in a five-dimensional Riemann space:

$$dS^2 = \gamma_{ab}dx^a dx^b$$

(1)
where $a, b = 1, \ldots, 5$ and $\gamma_{ab}$ denote the elements of the metric tensor.

In a flat space we introduce the Cartesian coordinates $x^1, x^2, x^3 = x, y, z, x^4 = ct, x^5 = cu$ where $c$ denotes the speed of light in the vacuum while $t$ and $u$ are expressed in the units of time. The non-zero components of the metric tensor are: $\gamma_{11} = \gamma_{22} = \gamma_{33} = -1, \gamma_{44} = 1$ and $\gamma_{55} = 1$ since time character is ascribed to the fifth coordinate.

With

$$(x^1, x^2, x^3, x^4, x^5) = (r, \theta, \varphi, ct, cu) \quad (2)$$

the spherically-symmetric line element in a flat space has the form

$$dS^2 = -dr^2 - r^2(d\theta^2 + \sin^2 \theta \, d\varphi^2) + c^2 dt^2 + c^2 du^2 \quad (3)$$

A general form of the spherically symmetric line element in a curved space is the following:

$$dS^2 = A(r, t, u) \, c^2 dt^2 + B(r, t, u) \, dr^2 + C(r, t, u) \, cd\!r\!d\!t + + D(r, t, u) \, (d\theta^2 + \sin^2 \theta \, d\varphi^2) + E(r, t, u) \, c^2 du^2$$

$$+ F(r, t, u) \, cd\!r\!d\!u + G(r, t, u) \, c^2 d\!t\!d\!u \quad (4)$$

In an appropriate coordinate system $r', t', u'$ we can assume that

$$C(r', t', u') = F(r', t', u') = 0 \quad (5)$$

and

$$D(r', t', u') = -r'^2 \quad (6)$$

In the following we shall omit the "prime" of the new coordinates $r', t'$ and $u'$ and we assume that the functions $A, B, E$, and $G$ in Eq. (4) are of the form:

$$A(r, t, u) = e^{\nu(r)} \quad B(r, t, u) = -e^{\lambda(r)}$$
$$E(r, t, u) = e^{\mu(r)} \quad G(r, t, u) = \sigma(r) \quad (7)$$

with $\mu, \nu, \lambda, \sigma \to 0$ when $r \to \infty$. The line element in Eq. (4) now takes the form:

$$dS^2 = -e^{\lambda} \, dr^2 - r^2(d\theta^2 + \sin^2 \theta \, d\varphi^2) + e^{\nu} \, c^2 dt^2 + e^{\mu} \, c^2 du^2 + \sigma \, c^2 d\!t\!d\!u \quad (8)$$

With the speed of light in the vacuum $c$ absorbed by the variables $t$ and $u$, the respective metric tensor components are

$$\gamma_{11} = -e^\lambda, \quad \gamma_{22} = -r^2, \quad \gamma_{33} = -r^2 \sin^2 \theta, \quad \gamma_{44} = e^\nu, \quad \gamma_{55} = e^\mu, \quad \gamma_{45} = \gamma_{54} = \sigma \quad (9)$$

The determinant $\gamma$ of this metric tensor is given by

$$\gamma = r^4 \, e^{\lambda} \, \sin^2 \theta \, (\sigma^2 - e^{\mu+\nu}) \quad (10)$$

The line element in Eq. (8) is analogous to that considered by Chodos and Detweiler in Eq. (17) of [16], however, in that paper the fifth coordinate is a space coordinate, while we assign a time character to the fifth coordinate. Consequently, the spherically symmetric solution connected with the line element in Eq. (8) will be of a different form than in [16].

When all derivatives with respect to the times $t$ and $u$ are omitted, denoting by a "prime", the derivative $d/dr$ we obtain the following non-zero components of the contracted Riemann tensor
The parameters $\mathcal{G}$ and $\mathcal{C}$ will be related with gravitational mass and electric charge, respectively, on the basis of the linearized form of the geodesic equation.
III. THE PARAMETERS IN THE SPHERICALLY-SYMMETRIC SOLUTION

We consider the two-times-independent metric tensor of the form:

$$\gamma_{ab} = \gamma_{(5)}^{ab} + \eta_{ab}, \quad a, b = 1, \ldots, 5$$ (20)

where $\gamma_{(5)}^{ab}$ is the five-dimensional flat-space metric tensor specified after Eq. (1), and $\eta_{ab}$ represents a small perturbation, due to the presence of a gravitating body with an electric charge. The perturbation vanishes very far from the body. To show that the $\eta_{ab}$ terms are the agents of gravitational and electrostatic forces we consider the geodesic equation of motion in the Riemann space with the above metric. We assume that the velocity of a test particle (with mass and electric charge) along the geodesic line is much smaller than the speed of light $c$. Using the nearly flat-space metric tensor in Eq. (20) we then obtain the line element

$$dS^2 = -(dx^1)^2 - (dx^2)^2 - (dx^3)^2 + (dx^4)^2 + (dx^5)^2 + \eta_{ab}dx^a dx^b$$ (21)

from which we obtain:

$$\left(\frac{dS}{dt}\right)^2 = c^2 \left[ 1 - \frac{v^2}{c^2} \left( \frac{du}{dt} \right)^2 + \frac{1}{c^2} \eta_{ab} \frac{dx^a}{dt} \frac{dx^b}{dt} \right]$$ (22)

where $v^j = dx^j / dt$, $j = 1, 2, 3$. Retaining in Eq. (22) the terms of the first order in $v/c$ we obtain:

$$\left(\frac{dS}{dt}\right)^2 \approx c^2 \left[ 1 + \left( \frac{du}{dt} \right)^2 (1 + \eta_{55}) + \eta_{44} + 2 \eta_{45} \frac{du}{dt} \right]$$ (23)

We had to assume that $v^2/c^2 \ll (du/dt)^2$, since otherwise we would have to omit $(du/dt)^2$ together with $v^2/c^2$.

We next apply the same approximations to the geodesic equation

$$\frac{d^2x^a}{dS^2} + \Gamma^a_{bc} \frac{dx^b}{dS} \frac{dx^c}{dS} = 0$$ (24)

From the form of the metric in Eq. (21) follows that each Christoffel symbol linearly depends on the perturbation $\eta_{ab}$. With the accuracy to terms of order $v/c$ we obtain the equality

$$\Gamma^a_{bc} \frac{dx^b}{dS} \frac{dx^c}{dS} = c^2 \left[ \Gamma^a_{44} + 2 \frac{du}{dt} \Gamma^a_{45} + \left( \frac{du}{dt} \right)^2 \Gamma^a_{55} \right] \left( \frac{dt}{dS} \right)^2$$ (25)

From Eq. (24) and (25) follows the equation

$$\frac{d^2x^a}{dt^2} = c^2 \left[ \Gamma^a_{44} + 2 \frac{du}{dt} \Gamma^a_{45} + \left( \frac{du}{dt} \right)^2 \Gamma^a_{55} \right]$$ (26)

Since $\eta_{ab}$ are independent of $t$ and $u$ the Christoffel symbols in Eq. (25) vanish for $a = 4, 5$. For $a = 1, 2, 3$ we have

$$\Gamma^a_{44} = \frac{1}{2} \frac{\partial \eta_{44}}{\partial x^a}, \quad \Gamma^a_{45} = \frac{1}{2} \frac{\partial \eta_{45}}{\partial x^a}, \quad \Gamma^a_{55} = -\frac{1}{2} \frac{\partial \eta_{55}}{\partial x^a}$$ (27)

and from Eq. (26), for $a = 5$ we find that $d^2u/dt^2 = 0$, hence

$$u = wt + u_0$$ (28)

where $w$ and $u_0$ are constants. With $u_0 = 0$, $w > 0$, considering Eqs. (27), and with $w = du/dt$ we obtain from Eq. (26) the equation
\[
\frac{d^2 x^a}{dt^2} = -\frac{c^2}{2} \left[ \frac{\partial \eta_{44}}{\partial x^a} + 2w \frac{\partial \eta_{45}}{\partial x^a} + w^2 \frac{\partial \eta_{55}}{\partial x^a} \right]
\]  
(29)

On the basis of this equation we will determine the parameters \(G\) and \(C\) in Eqs. (18) and (19).

We assume that the test particle is an electron with mass \(m\). Multiplying both sides of Eq. (29) with \(m\), we can identify the first term on the r.h.s. with the gravitational force acting on the electron mass \(m\), and to one of the two remaining terms we can ascribe the meaning of the Coulomb force acting on the electron charge \(e\). It will appear that we have to relate the third term on the r.h.s. of Eq. (29) with the Coulomb force.

We begin with the first term on the r.h.s. of Eq. (29) and write:

\[
\left( m \frac{d^2 x^a}{dt^2} \right)_{\text{mechanical}} = -m \frac{c^2}{2} \frac{\partial \eta_{44}}{\partial x^a} = -m \frac{\partial \psi}{\partial x^a}
\]  
(30)

with \(\psi\) denoting the gravitational potential of the mass \(M\), where \(\kappa\) is the gravitational constant,

\[
\psi = -\kappa \frac{M}{r}
\]  
(31)

thus obtaining the equality

\[
\eta_{44} = \frac{2}{c^2} \psi
\]  
(32)

and from this and from Eq. (21), the equality

\[
\gamma_{44} = 1 + \eta_{44}
\]  
(33)

From the first of Eqs. (18) and from Eqs. (31), (32) and (33) we then find that

\[
G = \frac{2\kappa M}{c^2}
\]  
(34)

as in the case of the Schwarzschild solution in 4 dimensions.

We next consider the third term on the r.h.s of Eq. (29). Let \(M\) denote the proton mass and let \(\varphi\) denote the electrostatic potential of the proton charge \(Q\)

\[
\varphi = \frac{Q}{4\pi \varepsilon_0 r}
\]  
(35)

where \(\varepsilon_0\) denotes the vacuum electric permeability. On the basis of Eq. (29) we write

\[
\left( m \frac{d^2 x^a}{dt^2} \right)_{\text{electrical}} = -\frac{1}{2} mc^2 w^2 \frac{\partial \eta_{55}}{\partial x^a} = -e \frac{\partial \varphi}{\partial x^a}
\]  
(36)

for the electrostatic force acting on the electric charge \(e\) connected with the mass \(m\). From Eq. (36) and (37) we obtain

\[
\frac{1}{2} c^2 w^2 \eta_{55} = \frac{e}{m} \varphi = \frac{Q e}{4\pi \varepsilon_0 r m}
\]  
(37)

and hence

\[
\eta_{55} = \frac{2 e Q}{4\pi \varepsilon_0 m c^2 w^2 r}
\]  
(38)
On the other hand from the second of Eqs. (18) and from Eq. (21) we obtain

\[ \gamma_{55} = 1 + \eta_{55} = 1 - \frac{C}{r} \]  

(39)

From Eqs. (18) and (39) we find that

\[ C = -\frac{2eQ}{4\pi\varepsilon_0 mc^2w^2} \]  

(40)

From the second of Eqs. (19) and from Eq. (35) follows that \( C \) must be positive. This implies that when the charge \( Q \) is assumed positive, the charge \( e \) must be negative and vice versa. When \( e \) and \( Q \) are of the same sign the second condition in Eq. (19) cannot be fulfilled. This formula depends on the parameter \( w^2 = \left(\frac{du}{dt}\right)^2 \), which in connection with Eq. (23) has to be much larger than \( v^2/c^2 \).

We now can determine the parameter \( \mathcal{P} \) in Eq. (19). Owing to Eq. (40) we obtain

\[ \mathcal{P} = \sqrt{G} = \frac{1}{wc^2} \sqrt{\frac{\kappa M|eQ|}{\pi\varepsilon_0 m}} \]  

(41)

where \(-eQ\) in Eq. (40) has been replaced by \(|eQ|\), since \( e \) and \( Q \) must have opposite signs. With the gravitational constant \( \kappa = 6.673 \times 10^{-11} \text{ N \cdot m}^2/\text{kg}^2 \), the vacuum electric permeability \( \varepsilon_0 = 8.85 \times 10^{-12} \text{ N \cdot m} \cdot \text{C}^{-2} \cdot \text{V}^{-1} \cdot \text{m}^{-1} \), with \( e/m = 1.76 \times 10^{11} \text{ Q \cdot K} \), and the absolute value of electron charge \( |e| = 1.6 \times 10^{-19} \text{ Q} \), where N=newton, M=meter, K=kilogram, Q=coulomb, V=volt [18] identifying the mass \( M \) in Eq. (34) with the proton mass we find from Eq. (34) that

\[ G \approx 2.4 \times 10^{-54} \text{ M} \]  

(42)

With \( Q \) denoting the proton charge, from Eq. (40) we find that

\[ C \approx 5.6 w^{-2} \times 10^{-15} \text{ M} \]  

(43)

and then with \( Q = |e| \) from Eq. (41) we obtain

\[ \mathcal{P} \approx 1.2 w^{-1} \times 10^{-34} \text{ M} \]  

(44)

We now can answer the question for the Schwarzschild radius. From Eqs. (19), (34) and (40) we find that in Eq. (19)

\[ \mathcal{R} = G + C = 2.4 \times 10^{-54} \text{ M} + 5.6 w^{-2} \times 10^{-15} \text{ M} \]  

(45)

If \( w^{-2} \) is not extremely small, the Schwarzschild radius is determined by the parameter \( C \) connected with the electric charge of the proton.

We now explain why it is not possible to relate the term \( \mathcal{P}/r \) with the Coulomb potential. If \( \mathcal{P}/r \) were related with the Coulomb potential, from Eq. (29) we then would obtain:

\[ \left( m \frac{d^2 x^a}{dt^2} \right)_{\text{electrical}} = -mc^2 \frac{\partial \eta_{45}}{\partial x^a} = -e \frac{\partial \varphi}{\partial x^a} \]  

(46)

with \( \varphi \) defined in Eq. (35). From Eqs. (35) and (46) we would obtain:

\[ \eta_{45} = \frac{eQ}{4\pi\varepsilon_0 r mc^2w} \]  

(47)

and since from Eqs. (8) and (21) we have

\[ \gamma_{45} = \eta_{45} = \frac{\mathcal{P}}{r} \]  

(48)
we would find

\[ P = \frac{eQ}{4\pi \varepsilon_0mc^2w} \]  

(49)

The parameter \( C \) now is obtained from Eq. (49)

\[ C = P^2G^{-1} \]  

(50)

The parameter \( R \) is determined in Eq. (19). Inserting into Eq. (50) the numerical values for \( P \) and \( G \) given in Eqs. (44) and (42) we find that \( C \approx 3w^{-2} \times 10^{24} \text{M} \), hence, unless \( w^{-2} \) is extremely small, the respective \( R = G + C \) is unacceptable as a candidate for the Schwarzschild radius of the proton. This seems to indicate that we cannot identify the force connected with \( \eta_{45} \) with the Coulomb force between the central charge \( Q \) and the charge \( e \) of a test particle.

IV. THE RELATIVISTIC ENERGY-LEVEL FORMULA

We set up the variational problem for the square of the interval in Eq. (8) (see for example [19]) in the form

\[ \delta \int \left[ \left( 1 - \frac{G}{r} \right)c^2 \dot{t}^2 + \left( 1 - \frac{C}{r} \right)c^2 \dot{u}^2 + \frac{\sqrt{GC}}{r}c^2 \dot{t} \dot{u} - \left( 1 - \frac{G + C}{r} \right)^{-1} \dot{r}^2 - r^2 (\dot{\theta}^2 + \dot{\varphi}^2 \sin^2 \theta) \right] dS = 0 \]  

(51)

where the "dot" denotes \( d/dS \). The Euler-Lagrange equations for \( \theta, \varphi, t \) and \( u \) yield the equalities:

\[ \frac{d}{dS}(r^2 \dot{\theta}) - r^2 \dot{\varphi}^2 \sin \theta \cos \theta = 0 \]  

(52)

\[ \frac{d}{dS}(r^2 \dot{\varphi} \sin^2 \theta) = 0 \]  

(53)

\[ \frac{d}{dS} \left[ 2 \left( 1 - \frac{G}{r} \right) \dot{r} + \frac{\sqrt{GC}}{r} \dot{u} \right] = 0 \]  

(54)

\[ \frac{d}{dS} \left[ 2 \left( 1 - \frac{C}{r} \right) \dot{u} + \frac{\sqrt{GC}}{r} \dot{t} \right] = 0 \]  

(55)

Dividing the expression for the interval in Eq. (8) by \( dS^2 \) we obtain the equation for \( \dot{r} \)

\[ 1 = \left( 1 - \frac{G}{r} \right)c^2 \dot{t}^2 + \left( 1 - \frac{C}{r} \right)c^2 \dot{u}^2 + \frac{\sqrt{GC}}{r}c^2 \dot{t} \dot{u} - \left( 1 - \frac{G + C}{r} \right)^{-1} \dot{r}^2 - r^2 (\dot{\theta}^2 + \dot{\varphi}^2 \sin^2 \theta) \]  

(56)

We assign the charge \( Z|e| \) to the central mass and will determine the perinucleic motion of an electron in the Coulomb field. We observe that the term with \( \sqrt{GC} \) determines the main influence of the gravitational field, connected with the central singularity, on the energy levels. This influence is very small in comparison with the influence of the Coulomb field represented by the parameter \( C \). In Eqs. (44), (54), and (55) we omit the terms containing the factors \( G/r \) or \( \sqrt{GC}/r \), since they are small in comparison with the terms containing \( C/r \), thus obtaining from Eq. (56) the equation
\[ 1 = c^2 l^2 + (1 - \frac{C}{r}) c^2 u^2 - (1 - \frac{C}{r})^{-1} \dot{r}^2 - r^2 (\dot{\theta}^2 + \dot{\varphi}^2 \sin^2 \theta) \]  

(57)

By an appropriate orientation of the coordinate axes we can make \( \theta = \pi/2 \) and \( d\theta/dS = \dot{\theta} = 0 \), for some initial value of \( S \). From Eq. (52) then follows that for all values of \( S \) we have \( \theta = \pi/2 \). Substituting this value of \( \theta \) into Eq. (53) we obtain

\[ r^2 \frac{d\varphi}{dS} = k = \text{const} \]  

(58)

while from Eqs. (54) and (53) we obtain

\[ \frac{dt}{dS} = \tau = \text{const} \]  

(59)

and

\[ \frac{du}{dS} \left(1 - \frac{C}{r}\right) = \rho = \text{const} \]  

(60)

Substituting the expressions in Eqs. (58), (59) and (60) into Eq. (57) we obtain the equation for \( r = r(S) \)

\[ \left( \frac{dr}{dS} \right)^2 = \left[ c^2 (\tau^2 + \rho^2) - 1 \right] + (1 - c^2 \tau^2) \frac{C}{r} \frac{k^2}{r^2} + \frac{Ck^2}{r^3} \]  

(61)

From this equation in the new variable \( v = 1/r \), in the customary way \[19\] we obtain the equation

\[ v'' + v = A + \beta \frac{A}{v^2} \]  

(62)

where

\[ A = \frac{(1 - c^2 \tau^2) C}{2k^2} \quad \text{and} \quad \beta = \frac{3}{2} AC \]  

(63)

Eq. (62) determines the perinucleic motion.

We now intend to determine a formula for the energy levels of the test particle. From Eq. (51) we obtain the expression

\[ \frac{dr}{dS} \frac{dt}{dS} = \frac{\tau}{dt} \frac{dr}{dt} = \sqrt{\left[ c^2 (\tau^2 + \rho^2) - 1 \right] + (1 - c^2 \tau^2) \frac{C}{r} \frac{k^2}{r^2} + \frac{Ck^2}{r^3}} \]  

(64)

We take over from Sommerfeld (p. 277 in \[17\]) the quantization conditions

\[ \int m \frac{dr}{dt} d\tau = n_r \hbar, \quad n_r = 0, 1, 2, \ldots \]  

(65)

\[ \int m v^2 \frac{d\varphi}{dt} d\varphi = n_\varphi \hbar, \quad n_\varphi = 1, 2, 3, \ldots \]  

(66)
where \( m \) denotes the electron mass, and \( h \) is Planck’s constant. From Eq. (64) we find that

\[
m \frac{dr}{dt} = \sqrt{\frac{m^2}{\tau^2} \left( \left\{ c^2(\tau^2 + \rho^2) - 1 \right\} + (1 - c^2\tau^2) \frac{C}{\tau} - \frac{k^2}{\tau^2} + \frac{Ck^2}{\tau^2} \right)}
\]

(67)

From Eqs. (58) and (59) and from Eq. (66) we find that

\[
k = \tau mn \bar{\varphi}h
\]

(68)

where \( \bar{h} = h/2\pi \). The integral in Eq. (65) with the integrand given in Eq. (67) was calculated in [17]. It has the value

\[
I = \int \sqrt{A_0 + 2A_1 \frac{1}{\tau^2} + A_2 \frac{1}{\tau^4}} \, dr = -2\pi i \left( \frac{A_1}{\sqrt{A_0}} - \frac{A_1 A_3}{2A_2 \sqrt{A_2}} \right)
\]

(69)

where \( \sqrt{A_2} \) is negative imaginary. Comparing Eq. (67) with the integrand on the l.h.s. of Eq. (69) we find that

\[
A_0 = \frac{m^2}{\tau^2} \left( c^2(\tau^2 + \rho^2) - 1 \right) \quad A_1 = \frac{m^2}{2\tau^2} (1 - c^2\tau^2)C \quad A_2 = -\frac{m^2k^2}{\tau^2} = -n^2_\tau h^2 \quad A_3 = \frac{m^2}{\tau^2} Ck^2 = Cn^2_\tau h^2
\]

(70)

The three terms on the r.h.s. of Eq. (69) take the form

\[
-2\pi i \sqrt{A_2} = -2\pi n_\varphi h
\]

(71)

\[
2\pi i \frac{A_1}{\sqrt{A_0}} = 2\pi i \frac{m(1 - c^2\tau^2)C}{2\tau \sqrt{c^2(\tau^2 + \rho^2) - 1}}
\]

(72)

\[
\pi i \frac{A_1 A_3}{A_2 \sqrt{A_2}} = 2\pi \left( 1 - c^2\tau^2 \right) \frac{C^2 m^2}{4n_\varphi h^2}
\]

(73)

From Eqs. (54), (57), (64) and (69) through (73), introducing the expression for \( C \) given in Eq. (40), with \( \alpha = e^2/4\pi \varepsilon_0 hc \) we obtain the equality

\[
\frac{iZ\alpha(1 - c^2\tau^2)}{c^2(\tau^2 + \rho^2) - 1} \left( \frac{dt}{du} \right)^2 = n_r + n_\varphi - \left[ 1 - c^2\tau^2 \right] \frac{\alpha^2 Z^2}{c^2 \tau^2} \frac{(dt/du)^4}{n_\varphi}
\]

(74)

The respective expression for the relativistic Kepler motion in a flat space in Eq. (26) on p. 278 of [17] is given by

\[
\left( 1 + \frac{W}{m_0 c^2} \right)^{-2} = 1 + \frac{\alpha^2 Z^2}{\left[ n_r + \sqrt{n^2_\varphi - \alpha^2 Z^2} \right]^2}
\]

(75)

In Sommerfeld’s formula in Eq. (75) the rest energy \( m_0 c^2 \) is not included into the energy \( W \). If on the r.h.s. of Eq. (74) we put

\[
\frac{1 - c^2 \tau^2}{c^2 \tau^2 (du/dt)^4} = \frac{1}{2}
\]

(76)
then writing $\tau^2 = d^2 c^{-2}$ with real $d$, we obtain Eq. (76) in the form $2 - 2d^2 = d^2 (du/dt)^4$, which implies $d^2 < 1$. Taking Eq. (74) into account we can represent the square of Eq. (76) in the form

$$3 - \frac{2c^2 \rho^2}{d^2 - 1} = 1 + \frac{Z^2 \alpha^2}{n_r + n_\varphi - \frac{\alpha^2 Z^2}{2n_\varphi}} \tag{77}$$

The l.h.s. of this equality can be expressed through the energy $W$. Eq. (77) then leads to the Sommerfeld formula for the energy levels of an electron in a hydrogen-like atom, in which $\sqrt{n_r^2 - Z^2 \alpha^2}$ is approximated by $n_\varphi (1 - Z^2 \alpha^2 / 2n_\varphi)$.

We observe that an analogue of Eq. (74) referring to the gravitational interaction can be obtained. We start from Eq. (66) in which the terms depending on $C$ and $GC$ are neglected. This can be done since the conditions in Eq. (19) allow to put $C = 0$. We then obtain the equation

$$\frac{dr}{dS} = \sqrt{\left[ c^2 (\tau_1^2 + \rho_1^2) - 1 \right] + \left( 1 - c^2 \rho_1^2 \right) \frac{\mathcal{G}}{r} - \frac{k^2}{r^2} + \frac{Gk^2}{r^3}} \tag{78}$$

in which now we have

$$\frac{dt}{dS} \left( 1 - \frac{\mathcal{G}}{r} \right) = \tau_1 = \text{const} \tag{79}$$

$$\frac{d\rho}{dS} = \rho_1 = \text{const} \tag{80}$$

replacing $\tau$ and $\rho$ in Eqs. (79) and (66), respectively. If on the left hand side of Eq. (78) we introduce

$$\frac{dr}{dS} = \frac{dr}{dt} \frac{dt}{dS} = \frac{dr}{dt} \frac{\tau_1}{1 - \mathcal{G}/r} \tag{81}$$

we obtain an analogue of Eq. (67) in which under the square root there appear additional terms proportional to $1/r^4$ and $1/r^5$. The latter terms remain also when we omit the fifth dimension and consider four-dimensional relativity which means $\rho_1 = 0$ in Eq. (80). The respective integration can be performed and its result does not lead to the formula of the type in Eq. (74).

If, however, on the left hand side of Eq. (78) we write

$$\frac{dr}{dS} = \frac{dr}{du} \frac{du}{dS} = \frac{dr}{du} \frac{\tau_1}{1 - \mathcal{G}/r} \tag{82}$$

and apply the quantization condition in Eq. (65), with $dr/dt$ replaced by $dr/du$, and in Eq. (66) replace $d\varphi/dt$ by $d\varphi/du$ we obtain an analogue of Eq. (65), which leads to equality

$$\frac{i \alpha_g Z (1 - c^2 \rho_1^2)}{c \rho_1 \sqrt{c^2 (\tau_1^2 + \rho_1^2) - 1}} = n_r + n_\varphi - \left( \frac{1 - c^2 \rho_1^2}{c^2 \rho_1^2} \right) \frac{\alpha^2 Z^2}{n_\varphi} \tag{83}$$

which has the structure of Eq. (74), where $Zm = M$ denotes the mass at the origin of the coordinates with $m$ denoting the mass of the electron, and where $\alpha_g = km^2/\hbar c$ is the fine-structure constant of the gravitational interaction [15]. Although Eq. (83) does not seem to have an experimental significance it is worthwhile to point out, that it has been obtained with the help of the second time variable $u$. It cannot be obtained with the ordinary time variable $t$ employed in the quantization conditions.

V. CONCLUSIONS AND DISCUSSION

Assuming that in a non-compactified Kaluza-Klein theory the fifth coordinate $x^5$ has time character in the five-dimensional line element, we have determined a Schwarzschild type solution of the five-dimensional Einstein equations...
in the vacuum. The two independent parameters of that solution have been related with mass and electric charge, respectively. The solution is characterized with a Schwarzschild radius whose magnitude is predominantly determined by the electric-charge parameter.

The perihelic motion in four-dimensional relativity has a counterpart in the perinucleic motion of an electron in a Kaluza-Klein theory with two times. If the quantization conditions of the older quantum theory are included into the five-dimensional geometry, the perinucleic motion of an electron leads to the fine structure of line spectra, analogous to that determined by Sommerfeld's formula for hydrogen-like atoms.

The parameter \( C \) which determines the Schwarzschild radius and the parameter \( P \) connected with a new force depend on the derivative \( du/dt \) of the second time coordinate \( u \) with respect to the ordinary time coordinate \( t \). Their numerical values therefore hinge on the magnitude of that quantity. The indicated physical meaning of those parameters, however, is not impaired by the lack of knowledge of the magnitude of the quantity \( du/dt \) as long as it is not extremely large or extremely small in comparison with 1.

There exists an extensive literature concerning spherically-symmetric solutions in the Kaluza-Klein theory. We only name the five-dimensional spherically symmetric solutions determined by Chodos and Detweiler [16], by Ponce de Leon and Wesson [20] and by Wesson [15]. Those solutions are based on the assumption of a spatial character of the fifth coordinate. A thorough discussion of those solutions is given in Overduin and Wesson [9] and in Wesson [15].

The presented results seem to contribute a new element to the discussion of two-time physics consequences.
