Abstract The Generalized Rectangular Fuzzy Assessment Model (GRFAM) is applied for the evaluation of student group acquisition of the van Hiele levels of geometric reasoning and an example is presented illustrating our results. The GRFAM is a variation of the Center of Gravity defuzzification technique created in an effort to treat better the ambiguous assessment cases being at the boundaries between any two successive assessment grades.

Keywords Fuzzy Sets (FS) and Logic (FL), Center of Gravity (COG), Defuzzification Technique, Generalized Rectangular Fuzzy Assessment Model (GRFAM), van Hiele (vH) Levels of Geometric Reasoning

1. Introduction

Situations appear frequently in our day to day life characterized by a degree of uncertainty and/or fuzziness. In Education for example, a teacher is frequently not sure about the degree of acquisition of the new knowledge by students, or for the proper mark to characterize a student’s performance. There used to be a tradition in science and engineering of turning to probability theory when a problem was faced in which uncertainty played an important role. Today this is no longer the rule. Fuzzy Logic (FL), due to its property of characterizing the ambiguous cases with multiple values, provides a rich and meaningful addition to standard logic enabling the mathematical modelling under conditions which are imprecisely defined, despite the concerns of classical logicians.

The authors of this article have frequently utilized principles of FL in past to describe and/or evaluate several human activities. Here the Generalized Rectangular Fuzzy Assessment Model (GRFAM) is applied for assessing the student group acquisition of the van Hiele (vH) levels of geometric reasoning.

The rest of the paper is formulated as follows: In Section 2 a brief account is given of the vH level theory and of several previous researches on it connected to the present work. In Section 3 we describe the GRFAM, while in Section 4 an example is presented illustrating its applicability for assessing the acquisition of the vH levels in Geometry by high school students. The last Section 5 includes our conclusion and some hints for future research.

For general facts on Fuzzy Sets (FS) and FL we refer to the book [5]. It is recalled here that a FS on the universal set of the discourse U (or a fuzzy subset of U) is a set of ordered pairs of the form A = {(x, m(x)) : x ∈ U}, where m: U → [0, 1] is its membership function. The closer is the membership degree y = m(x) of x to 1, the better x satisfies the characteristic property of A. Practically speaking, a FS is a set with no clear boundaries, e.g. the high mountains of a country, the good players of a team, the young inhabitants of a city, etc.

For reasons of simplicity many authors identify a fuzzy set with its membership function, the choice of which is not unique, depending upon the user’s personal criteria of goals. However, in order to represent correctly the corresponding real situation, the choice of the membership function must be compatible to the common sense.

2. The van Hiele Levels of Geometric Reasoning

It is generally accepted that the pedagogical value of the Euclidian geometry is great, mainly because it cultivates the student cognitive skills and connects directly mathematics to the real world. However, students face many difficulties for learning the Euclidian geometry, which fluctuate from the understanding of the space to the development of geometric reasoning and the ability of constructing the proofs and
The vH theory of geometric reasoning [12, 13] suggests that students can progress through five levels of increasing structural complexity. A higher level contains all knowledge of any lower level and some additional knowledge which is not explicit at the lower levels. Therefore, each level appears as a meta-theory of the previous one [2]. The five vH levels include:

- **L₁ (Visualization):** Students perceive the geometric figures as entities according to their appearance, without explicit regard to their properties.
- **L₂ (Analysis):** Students establish the properties of geometric figures by means of an informal analysis of their component parts and begin to recognize them by their properties.
- **L₃ (Abstraction):** Students become able to relate the properties of figures, to distinguish between the necessity and sufficiency of a set of properties in determining a concept and to form abstract definitions.
- **L₄ (Deduction):** Students reason formally within the context of a geometric system and they gasp the significance of deduction as means of developing geometric theory.
- **L₅ (Rigor):** Students understand the foundations of geometry and can compare geometric systems based on different axioms.

Obviously the level L₅ is very difficult, if not impossible, to appear in secondary classrooms, while level L₄ also appears very rarely.

Although van Hiele [13] claimed that the above levels are discrete – which means that the transition from one level to the next one does not happen gradually but all at once – alternative researches by Burnes & Shaughnessy [1], Fuys et al. [3], Wilson [20], Guttierrez et al. [4], and by Perdikaris [6] suggest that the vH levels are continuous characterized by transitions between the adjacent levels. This means that from the teacher’s point of view there exists fuzziness about the degree of student acquisition of each vH level. Therefore, principles of FL can be used for the assessment of student geometric reasoning skills.

3. The Generalized Rectangular Fuzzy Assessment Model

It is recalled that the solution of a problem in terms of FL involves in general the following steps:

- Choice of the universal set U of the discourse.
- Fuzzification of the problem’s data by defining the proper membership functions.
- Evaluation of the fuzzy data by applying rules and principles of FL to obtain a unique fuzzy set, which determines the required solution.
- Defuzzification of the final outcomes in order to apply the solution found in terms of FL to the original, real world problem.

One of the most popular in fuzzy mathematics defuzzification methods is the Centre of Gravity (COG) technique. According to this technique the fuzzy outcomes are represented by the coordinates of the COG of the level section contained between the graph of the corresponding membership function and the X-axis [11], which are calculated by known from Mechanics formulas; see formulas (1) in [8].

Subbotin et al. [7], based on a Voskoglou’s [14] fuzzy model for the process of learning a subject matter in the classroom, adapted the COG technique for use as an assessment method of student learning skills. Since then Subbotin and Voskoglou used the COG technique for assessing several other human activities. This method, named as the Rectangular Fuzzy Assessment Model (RFAM), was applied for assessing the student performance of two different Departments of the School of Technological Applications (prospective engineers) of the Graduate T. E. I. of Western Greece in the common final exam of the mathematics course of their first term of studies [8].

It is recalled that the membership function’s graph of RFAM consists of five adjacent rectangles corresponding to the fuzzy linguistic labels (grades) of excellent (A), very good (B), good (C), fair (D) and unsatisfactory (F) student performance respectively ([8], Figure 1).

Student performance can be assessed by numerical scores in a climax from 0-100. These scores are assigned to the above linguistic grades as follows: A (85-100), B (75-84), C (60-74), D (50-59) and F (0-49). Note that, the above assignment, although it satisfies the common sense, it is not unique; for example, in a more strict assessment one could take A(90-100), B(80-89), C(70-79), D(60-69) and F (0-59), etc.

![Figure 1. Graphical representation of the GRFAM](image)
corresponding calculations of the COG coordinates.

The graph of the resulting FS is now the bold line of Figure 1. However, the method used in ([8], Section 2) for calculating the coordinates of the COG is not the proper one here, because in this way the common rectangle parts are calculated only once. The right method for calculating the coordinates of the COG in this case was developed by Subbotin [10] and the resulting framework was called the Generalized Rectangular Fuzzy Assessment Model (GRFAM).

The development of GRFAM involves the following steps:

1. Let $y_i$, $y_j$, $y_k$, $y_l$, $y_m$ be the frequencies of a group’s members (e.g. students) who obtained the grades F, D, C, B, A respectively. Then $\sum_{i=1}^{5} y_i = 1 (100\%)$.

2. We take the heights of the rectangles in Figure 2 to have corresponding calculations of the frequencies of the rectangles lying on the OX axis to share common parts with lengths equal to the corresponding frequencies. Also, without loss of generality we allow the sides of the adjacent rectangles to have lengths equal to the corresponding frequencies. Therefore, the OX axis, from Figure 2 it is easy to observe that $x_i = 0.7i - 0.2$.

3. We calculate the coordinates $(x_i, y_i)$ of the COG, say $F_i$, of each rectangle, $i = 1, 2, 3, 4, 5$ as follows: Since the COG of a rectangle is the point of the intersection of its diagonals, we have that $x_i = \frac{1}{2} y_i$. Also, since the x-coordinate of each COG $F_i$ is equal to the x-coordinate of the middle of the side of the corresponding rectangle lying on the OX axis, from Figure 2 it is easy to observe that $x_i = 0.7i - 0.2$.

4. We consider the system of the COGs $F_i$ and we calculate the coordinates $(X_c, Y_c)$ of the COG $F$ of the whole area considered in Figure 2 as the resultant of the system of the GOCs $F_i$ of the five rectangles from the following well known [19] formulas

$$X_c = \frac{1}{S} \sum_{i=1}^{5} S_i x_i , \quad Y_c = \frac{1}{S} \sum_{i=1}^{5} S_i y_i , \quad (1)$$

In the above formulas $S_i, i = 1, 2, 3, 4, 5$ denote the areas of the corresponding rectangles, which are equal to $y_i$. Therefore $S = \sum_{i=1}^{5} S_i = \sum_{i=1}^{5} y_i = 1$ and formulas (1) give that

$$X_c = \sum_{i=1}^{5} y_i (0.7i - 0.2) , \quad Y_c = \sum_{i=1}^{5} (\frac{1}{2} y_i)$$

or

$$X_c = (0.7 \sum_{i=1}^{5} iy_i) - 0.2 , \quad Y_c = \frac{1}{2} \sum_{i=1}^{5} y_i^2 \quad (2).$$

5. We determine the area in which the COG F lies as follows: For $i, j = 1, 2, 3, 4, 5$, we have that $\theta \leq (y_i - y_j)^2 = y_i^2 + y_j^2 - 2y_i y_j$, therefore $y_i^2 + y_j^2 \geq 2y_i y_j$, with the equality holding if, and only if, $y_i = y_j$.

Therefore $1 = \sum_{i=1}^{5} y_i = \sum_{i=1}^{5} y_i^2 + 2 \sum_{i<j} y_i y_j \leq \sum_{i=1}^{5} y_i^2 + 2 \sum_{i,j=1, i \neq j} y_i y_j = 5 \sum_{i=1}^{5} y_i^2$ or $\sum_{i=1}^{5} y_i^2 \geq \frac{1}{5} (3)$, with the equality holding if, and only if, $y_1 = y_2 = y_3 = y_4 = y_5 = \frac{1}{5}$. In case of the equality the first of formulas (2) gives that $X_c = 0.7(\frac{1}{5} + \frac{2}{5} + \frac{3}{5} + \frac{4}{5} + \frac{5}{5}) = 1.9$. Further, combining the inequality (3) with the second of formulas (2), one finds that $Y_c \geq \frac{1}{10}$. Therefore the unique minimum for $Y_c$ corresponds to the COG $F_w (1.9, 0.1)$.

The ideal case is when $y_1 = y_2 = y_3 = y_4 = 0$ and $y_5 = 1$. Then formulas (2) give that $X_c = 3.3$ and $Y_c = 1$. Therefore the COG in this case is the point $F_i (3.3, 0.5)$.

On the other hand, the worst case is when $y_1 = 1$ and $y_2 = y_3 = y_4 = y_5 = 0$. Then from formulas (2) one finds that the COG is the point $F_w (0.5, 0.5)$. Therefore, the area in which the COG $F$ lies is the area of the triangle $F_w F_m F_1$(Figure 2).

6. From elementary geometric observations on Figure 2 one obtains the following assessment criterion:

- **Between two groups, the group with the greater $X_c$ performs better**: If two groups have the same $X_c \geq 1.9$, then the group with the greater $Y_c$ performs better.
- **If two groups have the same $X_c < 1.9$, then the group with the lower $Y_c$ performs better**: If two groups have the same $X_c < 1.9$, then the group with the lower $Y_c$ performs better.

From the first of formulas (2), in which greater coefficients are assigned to the higher scores, and the above criterion it becomes evident that the GRFAM measures the quality group’s performance. Also, since the ideal performance corresponds to the value $X_c = 3.3$, values of $X_c$ greater than $\frac{3.3}{2} = 1.65$ indicate a more than satisfactory

1 Since the ambiguous assessment cases are situated at the boundaries between the adjacent grades, it is logical to accept a percentage for the common lengths of less than 50% of the original lengths.
performance.

Note that two similar to GRFAM models were developed in ([8], Section 3), which were named as the Trapezoidal (TpFAM) and the Triangular (TFAM) Fuzzy Assessment Model respectively. The TpFAM was developed by replacing the rectangles of GRFAM with isosceles trapezoids (see also [9]) and the TFAM by replacing them with isosceles triangles. The formulas calculating the COG in these models are:

\[ X_c = (0.7\sum_{i=1}^{5} y_i) - 0.2, \quad Y_c = a \sum_{i=1}^{5} y_i^2 \]

for TpFAM and \( a = \frac{1}{5} \) for TFAM, while the assessment criterion remains the same in both cases as the above criterion for GRFAM. On comparing formulas (2) and (4) in terms of this criterion it turns out that GRFAM, TpFAM and TFAM are equivalent models providing always the same assessment outcomes. In other words, the shape of the membership function’s graph does not affect the assessment conclusions.

4. Assessing the Acquisition of the Van Hiele Levels by Students

Gutierrez et al. [4] presented a paradigm for evaluating the acquisition of the vH levels in three-dimensional Geometry by three different groups, say G1, G2 and G3, consisting of 20, 21 and 9 students respectively. Here, in order to illustrate the applicability of the GRFAM to the vH level theory, we shall use the data of this paradigm, which are depicted in Table 1.

| Group | vH level | F | D | C | B | A |
|-------|---------|---|---|---|---|---|
| G1    | L1      | 0 | 0 | 0 | 0 | 20|
| G1    | L2      | 1 | 0 | 3 | 6 | 10|
| G1    | L3      | 2 | 3 | 6 | 6 | 3 |
| G2    | L1      | 0 | 0 | 1 | 2 | 18|
| G2    | L2      | 0 | 3 | 4 | 13 | 1 |
| G2    | L3      | 9 | 6 | 5 | 1 | 0 |
| G3    | L1      | 0 | 2 | 4 | 2 | 1 |
| G3    | L2      | 3 | 4 | 2 | 0 | 0 |
| G3    | L3      | 9 | 0 | 0 | 0 | 0 |

From the first row of Table 1 one finds that \( y_1 = 1 \) and \( y_2 = y_3 = y_4 = 0 \) for \( L_1 \) in \( G_1 \). Therefore, the first of formulas (2) gives that \( X_c = 3.3 \). Similarly, from the fourth row of Table 1, one finds that \( y_1 = y_2 = 0 \), \( y_3 = \frac{1}{21} \), \( y_4 = \frac{2}{21} \) and \( y_5 = \frac{18}{21} \). Therefore, \( X_c = \frac{3}{21} + \frac{8}{21} + \frac{90}{21} \approx 3.17 \) for \( L_1 \) in \( G_2 \). In the same way one finds that the values of \( X_c \) are 2.06 for \( L_1 \) in \( G_3 \), 2.74, 2.3, 1.12 for \( L_2 \) in \( G_1 \), \( G_2 \), \( G_3 \) respectively and 2.08, 1.17, 0.5 for \( L_3 \) in \( G_1 \), \( G_2 \), \( G_3 \) respectively. Therefore, according to the first case of the assessment criterion of Section 3, \( G_1 \) demonstrated the best performance in the first three vH levels, followed by \( G_2 \) and \( G_3 \).

Also, on comparing the above values with 1.65, one concludes that \( G_1 \) demonstrated a more than satisfactory performance in these three levels, while \( G_2 \) demonstrated a more than satisfactory performance in the first two levels and \( G_3 \) demonstrated a more than satisfactory performance only in the first level.

Finally, since the mean value \( \frac{3.3 + 3.17 + 2.06}{3} \approx 2.84 \), \( G_1 \) demonstrated a more than satisfactory overall performance in the first three vH levels. In the same way, since the corresponding mean values for \( G_2 \) and \( G_3 \) are 2.21 and 1.08 respectively, \( G_2 \) demonstrated also a more than satisfactory overall performance, while the performance of \( G_3 \) was not satisfactory.

5. Conclusion and Hints for Future Research

In this work we applied the GRFAM for assessing the acquisition of the vH levels for geometric reasoning theory. The application of the GRFAM was proved to be very simple, while its conclusions can be easily interpreted.

Other fuzzy assessment methods have been also used in earlier works like the measurement of a system’s uncertainty ([15, 18], etc.), and the application of the fuzzy numbers ([16, 17], etc.). These methods, in contrast to GRFAM which focuses on the corresponding group’s quality performance, measure the group’s mean performance. Our plans for future research include the effort to compare the outcomes of all these methods in order to obtain the analogous conclusions.
