Review of direct CP violation in two and three body B decays at LHCb

Marc Grabalosa Gándara

LPC - Clermont Ferrand, CNRS, France

Charmless B hadrons decays offer rich opportunities to test the Standard Model. CP violation in charmless charged two-body and three-body B decays provides ways to measure the CKM angle $\gamma$ and to search for New Physics. Also, vector-vector final states provide additional interesting observables. Hereby, we present the latest LHCb results on hadronic charmless B decays putting emphasis on the direct CP violation measurements.

PRESENTED AT

8th International Workshop on the CKM Unitarity Triangle (CKM 2014)
Vienna, Austria, September 8-12, 2014

1On behalf of the LHCb Collaboration.
1 Introduction

Charmless b-hadron decays are a testing ground for the Standard Model as they have contributions from Tree and Penguin diagrams and CP violation may arise from the interference of both. In particular, the measurement of CP violation observables, as well as branching ratio measurements, can lead to an improvement of the CKM matrix elements. Here, we report the latest analysis performed on charmless B decays by the LHCb detector [1].

2 CP violation in the charmless $B_{(s)}^{0} \rightarrow K^{\pm} \pi^{\mp}$

The $B^{0} \rightarrow K^{\pm} \pi^{\mp}$ and $B_{s}^{0} \rightarrow \pi^{\pm} K^{\mp}$ decays can be used for the measurement of direct CP violation by looking at the so-called CP asymmetry which can be defined looking at the decay rates of the self-tagged modes as

$$A_{CP}(B^{0} \rightarrow K^{+} \pi^{-}) = \frac{\Gamma(B^{0} \rightarrow K^{-} \pi^{+}) - \Gamma(B^{0} \rightarrow K^{+} \pi^{-})}{\Gamma(B^{0} \rightarrow K^{-} \pi^{+}) + \Gamma(B^{0} \rightarrow K^{+} \pi^{-})}.$$ 

This asymmetry has been recently measured by the LHCb with 1 fb$^{-1}$ of data at center-of-mass energy 7 TeV [2]. After an efficient selection which takes into account different optimizations for $B^{0}$ and $B_{s}^{0}$ modes, the signal candidates are used to measure the raw asymmetry which are later corrected for detection and production asymmetries. Their measured CP asymmetries are

$$A_{CP}(B^{0} \rightarrow K^{+} \pi^{-}) = -0.080 \pm 0.007(\text{stat}) \pm 0.003(\text{syst})$$

$$A_{CP}(B_{s}^{0} \rightarrow \pi^{+} K^{-}) = 0.27 \pm 0.04(\text{stat}) \pm 0.01(\text{syst})$$

being the most precise measurement (10.5$\sigma$) of CP violation in $B^{0} \rightarrow K^{\pm} \pi^{\mp}$ and the first observation (6.5$\sigma$) of CP violation in $B_{s}^{0}$ decays.

3 CP violation on $B^{\pm} \rightarrow h^{\pm} h^{+} h^{-}$

Charmless three-body decays are dominated by processes involving intermediate resonances, and thus, rich interference patterns may arise. After the first evidence of CP violation in $B^{\pm} \rightarrow h^{\pm} h^{+} h^{-}$ [3, 4], an update of the analysis is performed with 3 fb$^{-1}$ [5] with the aim of measuring CP violation inclusively but also in the phase space by looking for CP violation asymmetries in local regions of the Dalitz plot.

New selection criteria including a multivariate technique and new particle identification variables are used. The signal candidates are extracted from an unbinned maximum likelihood fit to the mass spectra of the selected candidates: $B^{\pm} \rightarrow K^{\pm} \pi^{+} \pi^{-}$, $B^{\pm} \rightarrow K^{\pm} K^{+} K^{-}$, $B^{\pm} \rightarrow \pi^{\pm} \pi^{+} \pi^{-}$ and $B^{\pm} \rightarrow \pi^{\pm} K^{+} K^{-}$. After including the effects
induced by the detector and for the $B$ meson production asymmetry and correcting
for the acceptance to take into account the non uniformity of the efficiencies, the CP
violation asymmetries were measured to be

$$
A_{CP}(B^\pm \to K^\pm \pi^+ \pi^-) = +0.025 \pm 0.004\text{(stat)} \pm 0.004\text{(syst)} \pm 0.007(A_{CP}(J/\psi K))
$$

$$
A_{CP}(B^\pm \to K^\pm K^+ K^-) = -0.036 \pm 0.004\text{(stat)} \pm 0.002\text{(syst)} \pm 0.007(A_{CP}(J/\psi K))
$$

$$
A_{CP}(B^\pm \to \pi^+ \pi^+ \pi^-) = +0.058 \pm 0.008\text{(stat)} \pm 0.009\text{(syst)} \pm 0.007(A_{CP}(J/\psi K))
$$

$$
A_{CP}(B^\pm \to K^\pm K^+ K^-) = -0.123 \pm 0.017\text{(stat)} \pm 0.012\text{(syst)} \pm 0.007(A_{CP}(J/\psi K)).
$$

To study the CP asymmetries in local regions of the Dalitz plots, an adaptative
binning to keep the same events per bin was developed; the background was sub-
tracted using sWeights \cite{6} and corrections were applied to take into account accep-
tance effects. Large local raw asymmetries in certain regions of the phase space were
observed. The projections on the $m_{hh}$ divided according to the sign of the cosine of
the angle between the momenta of the unpair hadron and the resonant daughter with
the same-sign charge ($\theta_p$) were also studied, as seen in Figure 1.

Figure 1: Yields and asymmetries for $B^\pm \to \pi^\pm \pi^+ \pi^-$ when $\cos \theta_p < 0$ as a function of $m_{\pi\pi}$.

The charge asymmetry sign flip near the resonance seems to indicate a dominance
of the long-distance interference. In addition, negative and positive charge asymme-
tries are also found in the rescattering ($\pi\pi \leftrightarrow KK$) region defined between $1 < (m_{\pi\pi} or m_{KK}) < 1.5$ GeV/c$^2$.

4 First evidence of CPV in baryonic $B$ decays

The $B^\pm \to p\bar{p}h^\pm$ decays are studied to look for CP violation in baryonic modes
on the full 3 fb$^{-1}$ sample produced in LHCb run I \cite{7}. The yields are extracted
with an unbinned maximum likelihood fit to the $B^\pm \to p\bar{p}K^\pm$ and $B^\pm \to p\bar{p}\pi^\pm$ candidates. The Dalitz plots were studied after substracting the background using sWeights
and after correcting for acceptance effects, observing clear evidences of the charmonium resonances ($J/\psi, \psi(2S)$ and $\eta_c$), an enhancement at low $m_{p\overline{p}}^2$ and some hints of $\Lambda(1520) \rightarrow pK^-$, for which the branching ratio was computed using $B^\pm \rightarrow J\psi K^\pm$ as control channel, obtaining

$$BR(B^\pm \rightarrow \Lambda(1520)(\rightarrow pK^-)p) = (3.15 \pm 0.48\text{(stat)} \pm 0.07\text{(syst)} \pm 0.26(B^0 \rightarrow J/\psi K^*)) \times 10^{-7}.$$  

The $B^\pm \rightarrow p\overline{p}h^\pm$ dynamics are studied below the charmonium threshold region ($m_{p\overline{p}} < 2.85$ GeV/c$^2$), the acceptance-corrected distribution of the cosine of the helicity angle $\theta_p$ shows opposite behaviour of the two modes, which can be generated by non-resonant scattering. This distribution can be used to compute the forward backward asymmetry

$$A_{FB}(p\overline{p}K^\pm < 2.85 \text{ GeV}/c^2) = +0.495 \pm 0.012\text{(stat)} \pm 0.007\text{(syst)}$$

$$A_{FB}(p\overline{p}\pi^\pm < 2.85 \text{ GeV}/c^2) = -0.409 \pm 0.033\text{(stat)} \pm 0.006\text{(syst)}.$$  

For $B^\pm \rightarrow p\overline{p}K^\pm$ the Dalitz plane was obtained, observing negative and positive CP asymmetries in different regions of the phase space as seen in Figure 2.

![Figure 2: Dalitz plot and CP raw asymmetry for $B^\pm \rightarrow p\overline{p}K^\pm$.](image)

For the region $m_{p\overline{p}} < 2.85$ GeV/c$^2$ and $m_{Kp}^2 > 10$ GeV$^2$/c$^4$ a 4$\sigma$ evidence of CPV is found, being the first evidence of CP violation in baryonic B decays. The CP asymmetry is measured to be

$$A_{CP}(p\overline{p}K^\pm, m_{p\overline{p}} < 2.85 \text{ GeV}/c^2, m_{Kp}^2 > 10 \text{ GeV}^2/c^4) = 0.096 \pm 0.024\text{(stat)} \pm 0.004\text{(syst)}.$$  

## 5 Polarization and CP asymmetries on $B^0 \rightarrow \phi K^*$

According to the SM, the $B^0 \rightarrow \phi K^*(892)^0$ proceeds mainly via a gluonic penguin diagram, and thus, it is sensitive to new physics as new contribution may arise inside the loop.
A simultaneous mass and angular analysis is performed on the $B^0 \to \phi K^*(892)^0$ and their decay products with 1 fb$^{-1}$ of data [8]. Polarization amplitudes and phases are measured being longitudinal and transverse components of roughly equal amplitudes and their CP asymmetries compatible with zero as shown in Table 1.

| Parameter | LHCb             | CP parameter | LHCb             |
|-----------|------------------|--------------|------------------|
| $f_L$     | $0.497 \pm 0.019 \pm 0.015$ | $A_{CP}^\parallel$ | $-0.003 \pm 0.038 \pm 0.005$ |
| $f_\perp$ | $0.221 \pm 0.016 \pm 0.013$ | $A_{CP}^\perp$ | $+0.047 \pm 0.072 \pm 0.009$ |
| $\delta_{\perp}$ | $2.633 \pm 0.062 \pm 0.037$ | $\delta_{CP}^\perp$ | $+0.062 \pm 0.062 \pm 0.006$ |
| $\delta_{\parallel}$ | $2.562 \pm 0.069 \pm 0.040$ | $\delta_{CP}^\parallel$ | $+0.045 \pm 0.068 \pm 0.015$ |

Table 1: Parameters measured in the angular analysis. The first and second uncertainties are statistical and systematic, respectively.

The direct CP asymmetry rate is measured with respect to the $B^0 \to J/\psi K^*$ channel. $\Delta A_{CP} = (+1.5 \pm 3.2 \pm 0.5)\%$ is consistent with zero and the most precise measurement up to date.

6 Conclusions

A short review on the latest LHCb results on charmless 2- and 3-body decays is presented. The most precise CP violation in $B^0 \to K^\pm \pi^\mp$ has been obtained as well as the first evidence of CP violation in $B^0_s$ decays. In the $B^\pm \to h^+h^-h^-$ and $B^\pm \to p\bar{p}K^\pm$ channels, a large CP asymmetry has been found in regions of the Dalitz which do not correspond to resonant contributions, including the first evidence of CP violation in baryonic B decays. For the $B^0 \to \phi K^*(892)^0$ equal longitudinal and transversal polarization are obtained with CP asymmetries compatible with zero.
