Abstract. Chemo-photothermal therapy for cancer treatment has received increasing attention due to its selective therapeutic effects. In the present study, the anticancer effects of drug-loaded Fe₃O₄ magnetic nanoparticles (MNPs) by chemo-photothermal therapy on U-87 MG human glioblastoma cells was investigated. Anticancer drug-loaded Fe₃O₄ MNPs were prepared by loading temozolomide (TMZ) and indocyanine green (ICG), and were characterized by X-ray diffraction, UV-vis spectroscopy, thermal gravimetric analysis, transmission electron microscope, as well as drug-loading capacity. Following treatment with near-infrared (NIR) light irradiation, the administration of Fe₃O₄-TMZ-ICG MNPs resulted in the apoptosis of U-87 MG glioblastoma cells through the generation of reactive oxygen species. Western blot analysis and reverse transcription-quantitative polymerase chain reaction revealed that Fe₃O₄-TMZ-ICG MNPs with NIR laser irradiation lead to significantly enhanced anticancer effects on U-87 MG glioblastoma cells through the modulation of intrinsic and extrinsic apoptosis genes, including Bcl-2-associated X protein, Bcl-2, cytochrome c, caspase-3, Fas associated via death domain and caspase-8. These results suggest that Fe₃O₄-TMZ-ICG MNPs may be potential candidates when administered as chemo-phototherapy for the treatment of brain cancer.

Introduction

Glioblastoma (GBM) is the most common primary brain tumor of the central nervous system and has a high mortality rate, with a 4.5% 5-year relative survival rate in the US following diagnosis (1-3). A variety of cell types with fast growth potential in GBM and the blood-brain barrier (BBB), which controls the transportation of drugs, including antibodies, are major obstacles of GBM treatment (4,5). Thus, the development of a drug delivery system for GBM treatment is urgent to overcome issues associated with the BBB (6). Chemotherapy along with surgery and radiation therapy is the conventional methods for the treatment of patients with GBM (7). Temozolomide (TMZ), a commonly used oral anticancer drug inhibits the viability of malignant glioma cells with increased permeability through the BBB (8). Although TMZ can penetrate BBB, it shows low cytotoxicity against human glioma cells due to several cellular mechanisms of drug resistance (9). Therefore, a strategy for overcome this problem is required to increase the therapeutic efficacy of TMZ.

Chemotherapy in combination with phototherapy is considered an effective approach for treating brain cancer as of its minimal invasiveness (10). Photothermal therapy uses long-wavelength near-infrared (NIR) light with an absorption range, which allows a minimally invasive target treatment for tumor sites without affecting normal cells (11). It was reported that chemotherapeutic efficacy is generally increased in combination with photothermal therapy since the cytotoxicity of chemotherapeutic agents and drug delivery into cancer cells are enhanced at elevated temperatures (12-14). Currently, a number of inorganic and organic NIR photothermal agents, including metal-based particles such as Au (15,16), Ag (17), Pt (18,19), and Cu (20), graphene, and carbon-based nanomaterials (21), have been developed. However, these agents have drawbacks such as high toxicity and low photothermal conversion efficacy in the NIR range.

Magnetic nanoparticles (MNPs) as an effective cancer therapeutic agent and diagnostic contrast nanocomposite are widely applied the in biomedical field (22). Surface modifications of MNPs by introducing functional groups increase...
the efficacy of cancer therapy and bio-imaging through high drug-loading efficacy of MNPs and diagnostic contrast agent (23). In addition, as Fe3O4 MNPs possess broad absorption in the NIR range, they can be applied for photothermal therapy (24). Recently, studies have reported the photothermal conversion process of Fe3O4 MNPs based on the photoluminescence emission in the NIR region (25,26); however, few studies have sought to elucidate photothermal properties and conversion mechanism. Fe3O4 MNPs with a good photothermal conversion efficacy in the NIR region and low toxicity have been developed, and exhibited higher photothermal conversion efficiency than other photoabsorbers, such as noble metal-, carbon- and organic compound-based nanomaterials (27). Furthermore, efficient photothermal-induced hyperthermia using functionalized MNPs can induce synergistic anticancer effects in combination with chemotherapy (28).

Cancer cells are more vulnerable than normal cells due to their immature and disorganized vasculature (29-31). Thus, it is a feasible strategy for irreversible cellular damage through increasing therapeutic temperature (42-47°C) in the tumor region by photothermal therapy, leading to cellular apoptosis (32). Nanoparticle-mediated NIR thermal therapy depends on photothermal conversion efficacy and laser dosage (33). Additionally, the perfusion of blood and cellular membrane permeability can be improved by increasing the temperature in the tumor region by photothermal-induced local hyperthermia; thereby, the efficacy of drug delivery into the specific intracellular region is enhanced (34,35).

On the contrary, the photothermal effects of Fe3O4 MNPs alone is usually insufficient to deliver appropriate thermal energy because of inevitable laser light scattering and relatively poor specificity to target tumor area (36). To overcome these problems, the present study proposed ICG- and TMZ-loaded NIR laser irradiation and can convert absorbed NIR light to photothermal agent and photodynamic photosensitizer under an FDA-proved bifunctional NIR fluorescence dye, acts as a photothermal agent and photodynamic photosensitizer under NIR laser irradiation and can convert absorbed NIR light to thermal energy and reactive oxygen species (ROS) that are essential for photothermal and photodynamic therapy (37). However, its poor photo-stability is a major limiting factor for clinical application. In this study, we subsequently constructed TMZ- and ICG-loaded Fe3O4@SiO2 MNPs as a multimodal cancer therapeutic agent. ICG, an FDA-proved bifunctional NIR fluorescence dye, acts as a photothermal agent and photodynamic photosensitizer under NIR laser irradiation and can convert absorbed NIR light to thermal energy and reactive oxygen species (ROS) that are essential for photothermal and photodynamic therapy (37).

Materials and methods

Materials. Iron(III) acetylacetonate [Fe(acac)3], 1,2-hexadecanediol (90%), oleic acid (90%), oleylamine (70%), 1-octadecene (90%), cyclohexane, 1-hexanol, Triton X-100, tetraethyl orthosilicate (TEOS), ammonium hydroxide, 3-glycidoxypropyl trimethoxysilane (GPTMS), 4-formyl-phenylboronic acid (FPBA), polyethylenimine (PEI, 50 wt% solution in water), trimethylamine, tetrahydrofuran and TMZ were obtained from Sigma-Aldrich (Merck KGaA). Indocyanine green (ICG) was purchased from Thermo Fisher Scientific, Inc. Toluene, absolute ethanol (≥99.5%), n-hexane (≥99%) and dimethyl sulfoxide (DMSO) were obtained from Duksan Company. All commercial chemicals were used without further purification.

Preparation of Fe3O4@TMZ-IGC MNPs. The Fe3O4 magnetic core was synthesized by well-established thermal decomposition method (38). In brief, Fe(acac)3 (3 mmol), 1,2-hexadecanediol (10 mmol), 1-octadecene (20 ml), oleic acid (6 mmol) and oleylamine were stirred under nitrogen atmosphere and the resulting solution was heated to 100°C for 30 min. Then, the temperature was slowly increased to 200°C and stirred for 2 h. Subsequently, the mixture was refluxed at 320°C for 1 h with vigorous stirring and cooled down to room temperature. The products were precipitated by the addition of excess ethanol (99.5%) and purified by washing with n-hexane (99%) and ethanol repeatedly. The obtained materials were separated by centrifugation at 7,000 x g for 20 min at room temperature and re-dispersed in n-hexane.

The water soluble silica coated Fe3O4@SiO2-NH3 MNPs were prepared by the hydrolysis of TEOS (39) and the condensation reaction of GPTMS (40). First, 250 mg Fe3O4 MNPs was ultrasonically dispersed in a mixture of 20 ml cyclohexane, 4 ml 1-hexanol, 5 ml of Triton X-100 and 0.85 ml of water for 15 min at room temperature. To this, a 2.5 ml TEOS was dropped into the solution, and was vigorously stirred for 6 h at room temperature. Subsequently, a 0.5 ml ammonia solution (28% in water) was added and the solution was further stirred for 24 h. The precipitate was separated by an external magnet and washed with ethanol. The obtained product was dried in a vacuum oven at 60°C. Afterwards, ~200 mg Fe3O4@SiO2 MNPs was dispersed in 80 ml of anhydrous toluene and sonicated for 30 min at room temperature, and then 2 ml GPTMS was slowly dropped to this suspension under nitrogen atmosphere. Next, the mixture was stirred at 80°C for 24 h. After 24 h, the precipitate was separated by an external magnet and washed with toluene and ethanol, and then dried in vacuum oven overnight at 60°C.

Subsequently, Fe3O4@SiO2-NH3 MNPs for the drug and photosensitizer loading were modified with PEI and FPBA for ICG and TMZ conjugations, according to previous reports (41). First, PEI conjugation onto Fe3O4@SiO2-NH3 MNPs was performed via an epoxy ring opening reaction. 200 mg Fe3O4@SiO2-NH3 MNPs was added in 1.5 ml methanol containing 0.0025 mg/ml PEI and the dispersion was refluxed at 70°C for 24 h. After centrifugation at 7,000 x g for 20 min at room temperature, the precipitate was washed with ethanol and water for several times and dried at 70°C for 10 h. Then, 4-FPBA groups were grafted onto the surface of Fe3O4@PEI MNPs. 200 mg Fe3O4@PEI MNPs was dispersed in 300 ml methanol/acetic acid (124:1), after which 200 mg FPBA was added. The mixed solution was stirred at 40°C for 10 h. To eliminate the unstable Schiff base, 200 mg triethylamine was added to the resulting solution and stirred at 40°C for 10 h. The resultant Fe3O4@PEI-FPBA MNPs were collected and washed several times with water and ethanol.

For drug loading, Fe3O4@PEI-FPBA MNPs were modified with TMZ in the presence of succinic anhydride coupling agent (42). 20 mg Fe3O4@PEI-FPBA MNPs was ultrasonically dispersed in 5 ml methanol containing with 1 mg of TMZ for
Characterization of Fe$_3$O$_4$-TMZ-ICG MNPs. The crystal structures of the synthesized inorganic Fe$_3$O$_4$ and SiO$_2$-coated with Fe$_3$O$_4$ MNPs were analyzed by X-ray diffraction (XRD; X'Pert-MPD System; Philips Healthcare). The optical properties of modified Fe$_3$O$_4$ MNPs were observed under UV-vis spectroscopy (V-670; JASCO International Co., Ltd.). The quantities of organic functional groups and residual Fe$_3$O$_4$ content in the Fe$_3$O$_4$-TMZ-ICG MNPs were measured by thermal gravimetric analysis (TGA; TGA 7, Pyris 1; PerkinElmer, Inc.). Thermal curves of MNPs were measured with a heating rate of 10˚C/min from room temperature to 600˚C under a nitrogen atmosphere.

TMZ and ICG loading contents onto the modified Fe$_3$O$_4$ MNPs. The TMZ and ICG loading contents onto the modified Fe$_3$O$_4$ MNPs were determined by UV-vis spectroscopy (43). First, to determine TMZ loading efficiency, ~1.5 mg of Fe$_3$O$_4$-TMZ MNPs was transferred to 10 ml volumetric flask, and dissolved in 0.1 N hydrochloric acid (25 µg/ml) using an ultrasonic bath. The dispersion was centrifuged at 10,700 x g for 20 min at room temperature. The amount of loaded TMZ was determined by the difference in optical absorbance at 328 nm between the total amount of TMZ initially added to formation and the amount of free TMZ in the supernatant using UV-vis spectrophotometer (multiskan Go; Thermo Fisher Scientific, Inc.).

Next, to assess the ICG loading content, the optical absorption of conjugated ICG was measured by comparing absorption data at 780 nm before and after ICG conjugation onto the Fe$_3$O$_4$@PEI-FPBA MNPs under a UV-vis spectrometer. The ICG loading content was calculated based on the calibration curve of ICG concentration at 780 nm (44). The loading content and efficiency of TMZ and ICG molecules onto the Fe$_3$O$_4$ MNPs were calculated as follows (45):

\[
\text{Drug loading content} = \frac{\text{Amount of loaded TMZ (or ICG)}}{\text{Amount of TMZ (or ICG) loaded MNPs}} \times 100% \\
\text{Drug loading efficiency} = \frac{\text{Amount of loaded ICG (or TMZ)}}{\text{Total amount of TMZ (or ICG) initially added}} \times 100% 
\]

Particle size distribution and morphology of MNPs. The particle size and morphology were determined with a high-resolution transmission electron microscope (HR-TEM; JEM 2010; JEOL Ltd.). The mean size of Fe$_3$O$_4$ MNPs was measured by TEM operating at 200 kV FE (Field Emmission) with 1.43 Å resolution and their particle distribution were calculated by measuring the diameter of ~80 nanoparticles using image analysis software (ImageJ 1.52a; National Institutes of Health). The average hydrodynamic size of TMZ and ICG-functionalized Fe$_3$O$_4$@PEI-FPBA (Fe$_3$O$_4$-TMZ-ICG) MNPs were determined by a dynamic light scattering (DLS) analyzer (LS 13320; Beckman Coulter, Inc.) in cell media. The average size of nanoparticles was calculated by Gaussian histogram curve fitting.

Analysis of NIR photothermal heating effects. To investigate the photothermal effect of free ICG, Fe$_3$O$_4$ only, Fe$_3$O$_4$-ICG and Fe$_3$O$_4$-TMZ-ICG aqueous suspension with two different Fe$_3$O$_4$ concentrations (0, 125 and 250 µg Fe/ml) in water (1 ml), was irradiated with 808-nm NIR laser (Changchun New Industries Optoelectronics Technology), at a power density of 1 W/cm$^2$ for 10 min. The output power was adjusted by the measurement of a handy optical power meter (PMKIT-22-01; Newport Corporation). The temperature of the sample was detected using a thermal camera (FLIR i5; FLIR Systems, Inc.) above a sample holder as a function of irradiated NIR-light for the heat conversion effect.

Cell culture. U-87 MG, the human glioblastoma cell line was obtained from Korea cell line bank (cat. no. 30014). The U-87 MG cell line distributed by most cell collections (including the American Type Culture Collection, CLS and ECACC) is not the original glioblastoma cell line established in 1968 at the University of Uppsala, but the gene expression profile generated by the ATCC authentication indicates that this cell line is most probably also a glioblastoma cell line but whose origin is unknown (46). To ensure a human cell line for research, the STR profile of U-87 MG KCLB cell line was authenticated by comparing an STR profile of U-87 MG ATCC using the ATCC database. STR markers of U-87 MG KCLB cell line were identical to those of the accession no. CVCL-0022 of the U-87 MG ATCC cell line. Thus, the U-87 MG KCLB cell line was used as a cell model of a glioblastoma human cell line in this study.

The cells were cultured in a monolayer in Dulbecco's modified Eagle's medium (Thermo Fisher Scientific, Inc.), which was supplemented with 10% fetal bovine serum (Thermo Fisher Scientific, Inc.) and 1% (v/v) penicillin-streptomycin (Thermo Fisher Scientific, Inc.). The cultured cells were incubated at 37˚C in 5% CO$_2$, and the cell growth medium was replaced every 2 days. When the cells reached 80% confluence, the cells were harvested with 0.025% trypsin-EDTA solution.

Sample treatment and cancer photothermal therapy. For the photothermal therapy, U-87 MG cells were seeded at a density of 2x10$^5$ cells/well in a 24 well plate with 1 ml of cell medium and incubated for 24 h at 37˚C. The cells were treated with different samples for 2 h prior to exposure of NIR laser irradiation followed by incubation for 2 or 22 h. The cells without any treatment were used as a control. Both Fe$_3$O$_4$ MNPs and ICG were utilized as NIR light absorbers to efficiently convert optical energy into thermal energy (47). To deliver the optimal thermal energy to cancer cells, the concentration of ICG-entrapped Fe$_3$O$_4$ MNPs (Fe$_3$O$_4$-ICG-TMZ) was set to temperature in the range of 42-45˚C under 808 nm of laser at a power density 1 W/cm$^2$ for 5 min. The amount of Fe$_3$O$_4$ was equivalent in the Fe$_3$O$_4$, Fe$_3$O$_4$-ICG, and Fe$_3$O$_4$-ICG-TMZ MNPs samples (125 µg Fe/ml), and the amount of ICG was equivalent in the free ICG and Fe$_3$O$_4$-ICG-TMZ MNPs samples (3.1 µg/ml). To investigate synergistic chemo-photothermal therapy, the concentration of free TMZ was set to the amount of 10 min. Then, the mixture was stirred at 35-40˚C for 12 h. The resultant Fe$_3$O$_4$-TMZ MNPs were isolated by the removal of methanol and washed several times with methanol and water. Finally, for the photosensitizer loading, 1 mM ICG solution in DMSO was added in the Fe$_3$O$_4$-TMZ MNPs aqueous dispersion solution with a final DMSO concentration of 10% by volume and heated at 4˚C for 12 h. The obtained products were collected and washed several times with water and ethanol, and then stored in distilled water for further use.
Live/dead cell assay. After 22 h incubation at 37˚C with during photothermal therapy, a live/dead cell assay was sample and laser therapy, to evaluate cytotoxic effect in vitro pathway (49).

ROS generation and cell apoptosis. To confirm apoptosis induced by ROS generation, the cells were treated with samples and laser irradiation for 2 h. After 2 h further incubation at 37˚C, the cell medium was removed and the cells incubated in a final concentration of 10 µM dichloro-dihydro-fluorescein diacetate (DCFH-DA; Sigma-Aldrich; Merck KGaA) for 30 min at 37˚C. Cells were washed with PBS once, and ROS production was monitored under a fluorescence microscope at x200 magnification (Leica DMI300B; Leica Microsystems GmbH) and digital images were captured at least three different sites for each sample.

Next, to evaluate photothermal effect on cell viability, cell viability was detected using WST-1 cell viability assay kit (EZ-CyTox; Daeil Lab Inc.) according to the manufacturer’s protocols. The cells were seeded at a density of 1x10^4 cells/well in 96-well plates and incubated for 2 h at 37˚C. The cells were treated with various samples with or without laser irradiation. After 2 h incubation, the absorbance was measured at 450 nm using a microplate reader (Multiskan Go; Thermo Fisher Scientific, Inc.).

Flow cytometric analysis. To quantify in vitro cell cytotoxicity, flow cytometry was conducted. The cell population of live/apoptotic cells were analyzed using an Annexin V-FITC Apoptosis Detection Kit (BD Pharmingen™; BD Biosciences) according to the manufacturer's protocol by flow cytometry (BD FACSVerse; BD Biosciences). After 22 h incubation at 37˚C, floating and attached cells in the medium were collected by trypsinization. After collecting 5x10^5 cells by centrifugation at 600 x g for 1 min at 37˚C, cells were re-suspended in 100 µl of 1X binding buffer. The cell suspension was incubated with 10 µg/ml of Annexin V-FITC/PI double staining solution for 15 min at room temperature in the dark. An additional 400 µl 1X binding buffer was added to cell suspension, and then the fluorescence of cells was immediately analyzed with a flow cytometer.

Western blot analysis. After treatment for 24 h at 37˚C, the cells were washed twice with PBS, and lysed using a radioimmunoprecipitation assay buffer (Sigma-Aldrich; Merck KGaA) containing protease inhibitor (Roche Applied Science). Cytosolic and mitochondrial fractions for cytochrome c detection were isolated using a mitochondria isolation kit (Abcam) according to the manufacturer's instructions. The protein concentration was determined using a Pierce® BCA protein assay kit (Thermo Fisher Scientific, Inc.). Total protein (25 µg) was separated using 10% SDS-PAGE and then transferred to a nitrocellulose membrane. After blocking three times at each 5 min interval with 5% skim milk in TBS-T (Tris-buffered saline containing 0.1% Tween-20) at room temperature, the membrane was reacted with Bcl-2-associated X protein (Bax; cat. no. sc-20067, 1:200; Santa Cruz Biotechnology, Inc.), or cytochrome c (cat. no. sc-13561, 1:200; Santa Cruz Biotechnology, Inc.), caspase-3 (cat. no. sc-271759, 1:200; Santa Cruz Biotechnology, Inc.), cleaved caspase-3 (cat. no. 9661, 1:1,000; Cell Signaling Technology, Inc.), β-actin antibody (cat. no. sc-47778, 1:500; Santa Cruz Biotechnology, Inc.), or cytochrome c oxidase (COX IV; cat. no. sc-376731, 1:500; Santa Cruz Biotechnology, Inc.) overnight at 4˚C. The membrane was washed three times with TBS-T, 5 min each...
followed by incubation for 2 h with mouse IgG κ binding protein (m-IgGκ BP) conjugated to horseradish peroxidase (cat. no. sc-516102, 1:1,000; Santa Cruz Biotechnology, Inc.), or anti-rabbit IgG, HRP-linked secondary antibody (cat. no. 7074, 1:1,000; Cell Signaling Technology, Inc.) at room temperature. β-actin and COX IV were used as loading controls for whole cell and cytosolic proteins, and mitochondrial proteins, respectively.

After washing three times with TBS-T for 5 min, the bands were developed using an ECL Western Blotting Detection Kit Reagent (Thermo Fisher Scientific, Inc.) and imaged on Davinch-Chemi™ imaging system (CAS-400SM, Davinch-K). The relative band intensities of each target protein expression were quantitated using ImageJ software (version 1.52a), compared with the levels of the β-actin or COX IV protein expression as a reference.

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR). After treatment for 24 h, Total RNA was isolated using a TRIzol® reagent (Thermo Fisher Scientific, Inc.) and imaged on Davinch-Chemi™ imaging system (CAS-400SM, Davinch-K). The relative band intensities of each target protein expression were quantitated using ImageJ software (version 1.52a), compared with the levels of the β-actin or COX IV protein expression as a reference.

Statistical analysis. All statistics analyses were performed with Sigma Plot 12.0 (Systat Software Inc., San Jose, CA, USA). The levels of significance were calculated using a one-way ANOVA for comparisons with the control group. The experiments for each sample were repeated at least three times. Data are presented as the mean ± standard deviation. P<0.05 was considered to indicate a statistically significant difference.

Results and discussion

Characterization of Fe₃O₄-TMZ-ICG MNPs. The synthesis process of biocompatible Fe₃O₄-TMZ-ICG MNPs as chemo-photothermal therapeutic agents is presented in Fig. 1. The crystal structure of synthesized Fe₃O₄ MNPs was analyzed by XRD pattern (Fig. 2A). The distinctive intensities of (220), (311), (400), (422), (511) and (440) peaks at 2q=30.05, 35.39, 43.01, 53.36, 65.67 and 66.72°, which corresponded to inverse spinel structure of Fe₃O₄ (JCPDS 85-1436), were observed in the pristine Fe₃O₄ MNPs with well-defined crystallinity. After
silica coating, the obtained Fe₃O₄@SiO₂ MNPs in the crystalline structure showed the characteristic peaks of Fe₃O₄ MNPs and the additional broad peak of amorphous SiO₂ coating shell indexed as (012), which was observed at 20-30°. The intrinsic peaks of Fe₃O₄ MNPs were well-preserved during the process of functionalization with SiO₂.

The content of functional shells on the Fe₃O₄ MNPs were estimated by TGA (Fig. 2B). Weight reductions indicate the content of organic materials on the functionalized Fe₃O₄ MNPs. The decrease in weight at temperatures <200°C indicated the removal of residual adsorbed solvent in the MNPs, and that at temperatures >250°C was attributed to organic materials. The weight of each sample gradually decreased at >450°C under N₂ atmosphere. The TGA thermogram of Fe₃O₄ MNPs showed a constant weight reduction with increasing temperature as of the removal of free oleic acid and decomposition of oleic acid bound to Fe₃O₄ MNPs. The Fe₃O₄@SiO₂ MNPs showed notable weight loss, of ~35.95% at 250-450°C, mainly due to the decomposition of coated SiO₂-NH₂ on the Fe₃O₄ MNPs surface. The PEI-FPBA encapsulated Fe₃O₄ MNPs exhibited increased weight reductions of ~51.31% than Fe₃O₄ and Fe₃O₄@SiO₂-NH₂ MNPs due to the decomposition of coated PEI and FPBA on the Fe₃O₄ MNPs surface. At a temperature of 500°C, the functional shells on the Fe₃O₄ MNPs decomposed by ~100%. Using TGA thermogram analysis, final

Determination of TMZ- and ICG-loading contents. UV-vis spectroscopy was employed in order to confirm the successful TMZ- and ICG-loading onto the Fe₃O₄@PEI-FPBA MNPs (Fig. 2D). The Fe₃O₄-TMZ-ICG MNPs with maximum absorption at 328 and 780 nm revealed the presence of the condensation of TMZ and electrostatic interaction of ICG with Fe₃O₄@PEI-FPBA MNPs, which could be used to quantify the TMZ and ICG concentration. TMZ- and ICG-loading contents in Fe₃O₄-TMZ-ICG MNPs was determined by the difference of optical absorbance at 328 and 780 nm, respectively, after subtracting the optical absorbance of Fe₃O₄@PEI-FPBA
MNP before TMZ- and ICG-molecules loading. Based on the optical absorbance of TMZ- and ICG-molecules and the linear calibration curves of TMZ- and ICG-concentration at 328 and 780 nm, respectively, TMZ-loading contents were ~26.4 µg per 1.5 mg/ml of Fe$_3$O$_4$-TMZ-ICG aqueous solution. MNPs, and the loading efficiencies of TMZ and ICG were respectively found to be 35.2 and 21.4%. The calculated TMZ- and ICG-loading contents were determined to be ~ 6.6 and 3.1 µg per 173 mg of Fe$_3$O$_4$ MNPs (125 µg Fe/ml).

The Fe$_3$O$_4$-TMZ-ICG MNPs showed high optical absorption in the NIR region with a high drug loading efficiency of ≤50%, suggesting that the Fe$_3$O$_4$-TMZ-ICG MNPs can be applied in synergistic chemo-photothermal therapy under NIR laser irradiation.

**Photothermal performance of Fe$_3$O$_4$-TMZ-ICG MNPs.** The photothermal heating responses of free ICG, Fe$_3$O$_4$ only, Fe$_3$O$_4$-ICG, and Fe$_3$O$_4$-TMZ-ICG MNPs were examined with the different concentrations in water (1 ml) for 10 min with 808-nm NIR laser irradiation at 1 W/cm$^2$. As shown Fig. 3, the temperature of Fe$_3$O$_4$ solution upon 808-nm NIR laser irradiation was increased with the increase of Fe$_3$O$_4$ concentration and laser exposure time ($\Delta T=9.8^\circ$C at 125 µg Fe/ml and $\Delta T=16.5^\circ$C at 250 µg Fe/ml for 5 min, and $\Delta T=13.1^\circ$C at 125 µg Fe/ml and $\Delta T=22.2^\circ$C at 250 µg Fe/ml for 10 min), whereas the temperature of pure water showed no notable change. On the contrary, the temperature of free ICG solution quickly increased at the initial 4 min of exposure to 808-nm NIR laser irradiation, followed by the gradual decrease due to photo-degradation of ICG (55). ICG- and Fe$_3$O$_4$-conjugated MNPs (Fe$_3$O$_4$-ICG and Fe$_3$O$_4$-TMZ-ICG) exhibited higher heating efficiency with the sample concentration and laser exposure time ($\Delta T=23.8^\circ$C at 125 µg Fe/ml and $\Delta T=29.8^\circ$C at 250 µg Fe/ml for 5 min, and $\Delta T=27.7^\circ$C at 125 µg Fe/ml and $\Delta T=31.3^\circ$C at 250 µg Fe/ml for 10 min for Fe$_3$O$_4$-ICG; $\Delta T=23.1^\circ$C at 125 µg Fe/ml and $\Delta T=26.5^\circ$C at 250 µg Fe/ml for 5 min, and $\Delta T=26.8^\circ$C at 125 µg Fe/ml and $\Delta T=29.0^\circ$C at 250 µg Fe/ml for 10 min for Fe$_3$O$_4$-TMZ-ICG) compared with the Fe$_3$O$_4$ MNPs and ICG alone. Of note, the photostability of ICG entrapped in Fe$_3$O$_4$ MNPs markedly improved due to the reduced intramolecular interactions within ICG (56).

Further, the corresponding IR thermal camera images of ICG, Fe$_3$O$_4$, Fe$_3$O$_4$-ICG, and Fe$_3$O$_4$-TMZ-ICG solution during 10 min of NIR laser irradiation revealed homogeneous distribution of temperature with fast heat dissipation. These results indicate that ICG-entrapped Fe$_3$O$_4$ MNPs could be an effective photothermal agent with high heating ability and thermal stability.

**Detection of intracellular ROS generation by chemo-photothermal therapy.** ROS generation associated with cellular membrane damage was examined using ICG- and/or TMZ-conjugated Fe$_3$O$_4$ MNPs with NIR laser irradiation (Fig. 4). Intracellular production of ROS can cause irreversible damage to target cancer cells and triggering of apoptosis (57). NIR laser stimuli can induce cellular damage by not only the thermal effect, but also via heat stress-induced ROS during photothermal therapy to target cancer cells (58). Furthermore, several anticancer drugs induce ROS generation via oxidative stress (59). Importantly, in this study, ICG was proposed to be effectively applied as a photothermal agent and photodynamic photosensitizer to generate heat and toxic ROS upon NIR laser irradiation for the ablation of cancer cells (60).

The intracellular ROS generation in U-87 MG cells treated without sample, or 3.1 µg/ml ICG, 6.6 µg/ml TMZ, and 125 µg Fe/ml Fe$_3$O$_4$, Fe$_3$O$_4$-ICG and Fe$_3$O$_4$-TMZ-ICG MNPs with or without 808-nm NIR laser irradiation (1 W/cm$^2$, 5 min) after 2 h was confirmed by DCF green fluorescence stain under a fluorescence microscope. Without 808-nm NIR laser irradiation, all cells exhibited no considerable intracellular ROS production. In contrast, all cells treated with samples exhibited notable ROS production upon 808-nm NIR laser irradiation. In addition, as shown in Fig. 4I, the cells treated with TMZ- and ICG-loaded Fe$_3$O$_4$ (Fe$_3$O$_4$-TMZ-ICG) MNPs showed a strong green fluorescence intensity, which indicated considerably enhanced ROS production, along with higher cytotoxicity in cell morphology. ROS production was more strongly detected in the Fe$_3$O$_4$-TMZ-ICG MNPs-treated cells.

![Figure 3. Photothermally induced thermal responses of Fe$_3$O$_4$-TMZ-ICG magnetic nanoparticles. (A) Temperature elevation curves with 2 µg/ml free ICG, and 125 µg Fe/ml of Fe$_3$O$_4$, Fe$_3$O$_4$-ICG, and Fe$_3$O$_4$-TMZ-ICG aqueous solution. (B) Temperature elevation curves (left), and thermal camera images (right) of 4 µg/ml free ICG (2 µg/ml), and 250 µg Fe/ml of Fe$_3$O$_4$, Fe$_3$O$_4$-ICG, and Fe$_3$O$_4$-TMZ-ICG aqueous solution. Sample solution (1 ml) was transferred into a 24 well plate and compared as a function of sample concentration under 808 nm near-infrared laser irradiation at 1 W/cm$^2$ for 10 min. ICG, indocyanine green; TMZ, temozolomide.](image-url)
compared with the cells treated with ICG, TMZ, Fe₃O₄ MNPs or laser alone. Taken together, experimental results indicate that ROS production was synergistically enhanced by the combination of chemo-phototherapy using Fe₃O₄-TMZ-ICG MNPs.

**Morphological changes and cell viability by chemo-photothermal therapy.** To evaluate the cytotoxic effect in combination with the chemotherapeutic and phototherapeutic treatments, the U-87 MG cells were incubated with the different samples (3.1 µg/ml ICG, 6.6 µg/ml TMZ, and 125 µg Fe/ml of Fe₃O₄, Fe₃O₄-ICG and Fe₃O₄-TMZ-ICG MNPs) for 2 h, followed by 808-nm NIR laser irradiation at 1 W/cm² for 5 min. The cells were further incubated for 22 h, and then alterations in cell morphology were observed under an optical microscope (Fig. 5A). Both control cells and those treated with photothermal agents (ICG, Fe₃O₄ and Fe₃O₄-ICG MNPs) without 808-nm NIR laser treatment showed no marked morphological changes, suggesting that ICG, Fe₃O₄ only, and Fe₃O₄-ICG MNPs have high biocompatibility and low cytotoxicity in vitro (Fig. 5A). Cells treated with TMZ alone and TMZ-loaded Fe₃O₄-ICG MNPs as a chemo and chemo-photothermal agent without 808-nm NIR laser treatment (Fig. 5Ac and f), showed no considerable damage in cell morphology compared with control cells (Fig. 5Aa).

Conversely, with 808-nm NIR laser treatment, the cells treated with ICG, Fe₃O₄ and Fe₃O₄-ICG MNPs as photothermal agents showed notable cellular damage, such as cell shrinkage, nuclear condensation, and loss of cell volume (Fig. 5Ah, j and k), whereas the control showed no marked damage (Fig. 5Ag). In addition, the intracellular uptake of Fe₃O₄ MNPs into U-87 MG cells improved after NIR laser irradiation (Fig. 5Aj, k and l). Next, for the cells treated with TMZ, a chemotherapeutic agent for brain cancer (61), with 808-nm NIR laser treatment, there was a slight reduction in cell viability (Fig. 5Ai). Finally, the cells treated with TMZ-loaded Fe₃O₄-ICG MNPs, a chemo-photothermal agent with 808-nm NIR laser treatment, showed notable cellular damage with a reduction in the cell population.

Next, the viability of ICG, TMZ, Fe₃O₄ alone, Fe₃O₄-ICG and Fe₃O₄-TMZ-ICG MNPs with or without NIR laser irradiation was measured in U-87 MG cells by WST-1 assay (Fig. 5B). Without NIR laser irradiation, all cells presented almost comparable cell viability compared with that of the control. With NIR laser irradiation, the cells treated with TMZ only showed small reductions in cell viability (91.01%), whereas the control
group with NIR laser irradiation exhibited no marked changes in cell viability. There was no obvious change in temperature (data not shown). ICG and Fe₃O₄ MNPs with NIR laser irradiation revealed a total of 63.55% and 70.74% viable cells, respectively. The temperature increased up to 41.1 and 43.6°C for ICG and Fe₃O₄ MNPs, respectively (data not shown).
combination of ICG and Fe$_3$O$_4$ (Fe$_3$O$_4$-ICG) exhibited significantly decreased cell viability (21.37%), leading to a notable temperature increase to 51.8°C. Finally, the combination of ICG, TMZ and Fe$_3$O$_4$ (Fe$_3$O$_4$-TMZ-ICG) as a chemo-photothermal agent showed a significantly decreased cell viability of 9.32%, leading to an obvious temperature increase to 51.2°C.

According to these results, photothermal therapy by ICG, Fe$_3$O$_4$ and Fe$_3$O$_4$-ICG MNPs with 808-nm NIR laser irradiation induced marked morphological changes such as cell shrinkage, membrane integrity loss, and cytoplasmic condensation, evidencing the incidence of cell apoptosis (62). Moreover, Fe$_3$O$_4$-TMZ-ICG MNPs with 808-nm NIR laser irradiation induced severe cellular damage and showed significantly decreased in U-87 MG glioblastoma cell viability via the combination of chemo-photothermal therapy, resulting in subsequent irreversible cell death.

**Live/dead cell assay.** To further investigate the *in vitro* photothermal effect of combined chemo-photothermal therapy using TMZ- and ICG-loaded Fe$_3$O$_4$ MNPs, live cells detection after treatment with samples was carried out using calcein AM/PI double staining. As shown in Fig. 5C, the control U-87 MG cells with and without 808-nm NIR laser irradiation emitted green fluorescence as the calcein-AM reagent can penetrate the live cell membrane, indicating no apoptotic cells. Treatment with the ICG, Fe$_3$O$_4$ and Fe$_3$O$_4$-ICG MNPs without NIR laser irradiation showed green fluorescence, suggesting no cytotoxicity. In addition, treatment with TMZ and Fe$_3$O$_4$-TMZ-ICG MNPs showed slight morphological changes. However, treatment with Fe$_3$O$_4$ and ICG with NIR laser irradiation showed slight yellow-green calcein-AM nuclear staining with morphological damage, suggesting that there was the early cell apoptosis. Moreover, treatment with Fe$_3$O$_4$-TMZ-ICG MNPs with 808-nm NIR laser irradiation exhibited intense red fluorescence due to PI staining, suggesting that chemo-photothermal therapy using the Fe$_3$O$_4$-TMZ-ICG MNPs exhibited high cytotoxicity against U-87 MG cells.

To assess the live/dead cell ratio, calcein-AM and PI fluorescence intensities were quantified using ImageJ software (Fig. 5D). The cells treated with ICG, TMZ and/or Fe$_3$O$_4$ showed significantly increased cell death under NIR laser irradiation, as evidenced by fewer green spots and enhanced red spots in the images. These results demonstrated that chemo-photothermal therapy using Fe$_3$O$_4$-TMZ-ICG MNPs induced the synergetic effect for U-87 MG cancer cell killing capacity.

**Nanoparticles intracellular uptake and cellular damage.** To assess DNA damage-induced apoptosis by the synergistic combination of chemo-phototherapy, high-quality morphological images in single cells were observed via confocal microscopy. As shown in Fig. 6A-F, cells that unexposed to 808-nm NIR laser irradiation (i.e. no sample, 3.1 µg/ml ICG, 6.6 µg/ml TMZ, and 125 mg Fe/ml of Fe$_3$O$_4$, Fe$_3$O$_4$-ICG and Fe$_3$O$_4$-TMZ-ICG MNPs) showed no nuclear and cellular membrane damage. The cells treated with no sample (control) and TMZ with NIR laser irradiation also showed no notable nuclear and cellular membrane damage. On the contrary, the cells treated with ICG, Fe$_3$O$_4$, and ICG-conjugated Fe$_3$O$_4$ as photothermal agents under NIR laser irradiation exhibited considerable nuclear damage and the loss of cellular membrane integrity (Fig. 6G-L). In particular, as shown Fig. 6J-L, Fe$_3$O$_4$ nanoparticles exhibited enhanced intracellular nanoparticle uptake by 808-nm NIR laser stimulation, thereby leading to nucleus damage. These results suggest that Fe$_3$O$_4$-TMZ-ICG MNPs as a TMZ drug carrier were more highly internalized into the nucleus of cancer cells by NIR laser stimuli; TMZ from the surface of Fe$_3$O$_4$ MNPs may bind DNA contributing to efficient targeted drug delivery.

**Determination of cell apoptosis.** To investigate the synergetic anticancer effect of the combination of chemo-phototherapy compared to chemotherapy and phototherapy alone, flow cytometry analysis was conducted after treatment with samples (i.e., no sample, 3.1 µg/ml of ICG, 6.6 µg/ml of TMZ, and 125 µg Fe/ml of Fe$_3$O$_4$, Fe$_3$O$_4$-ICG and Fe$_3$O$_4$-TMZ-ICG MNPs) using Annexin V-FITC/PI double staining (Fig. 7). For the control with or without 808-nm NIR laser treatment, there was no cytoxicity, indicating the control group was not affected by NIR laser irradiation. For the cells after treatment with samples without 808-nm NIR laser, there were no significant cytotoxicity compared with the control. In contrast, the cells after treatment of samples with 808-nm NIR laser exhibited significantly higher cytotoxicity with an increase in the proportion of cell apoptosis, except for TMZ treatment. This suggested that the decrease in cell viability may be due to apoptosis by phototherapy and/or chemo-phototherapy. Here, the observed percentages of apoptotic cells (early and late apoptotic cells) after 808-nm NIR laser treatment were 2.06% in control, 35.3% in ICG-treated (3.1 µg/ml), 6.23% in control, 35.3% in ICG-treated (3.1 µg/ml), 6.23% in control, 35.3% in ICG-treated (3.1 µg/ml), and 85.58% in Fe$_3$O$_4$-TMZ-ICG-treated (125 µg Fe/ml) cells, respectively. Specifically, the Fe$_3$O$_4$-TMZ-ICG MNPs without 808-nm NIR laser irradiation showed a cytotoxicity of 6.7% against U-87 MG cells; however, U-87 MG cells treated with the Fe$_3$O$_4$-TMZ-ICG MNPs under 808-nm NIR laser irradiation showed significantly increased cell cytotoxicity of 96.68% after 12 h treatment. In addition, treatment with Fe$_3$O$_4$-TMZ-ICG and 808-nm NIR laser irradiation at 1 W/cm$^2$ for 5 min led to a total of ~80% apoptotic cells. Therefore, the Fe$_3$O$_4$-TMZ-ICG MNPs with 808-nm NIR laser irradiation at 1 W/cm$^2$ may be effectively utilized as a photothermal-induced anticancer therapeutic agent in synergistic cancer therapy.

**Promotion of intrinsic and extrinsic apoptotic pathway.** Apoptosis known as programmed cell death is regulated by specific cellular signaling pathways which maintain the balance between cell proliferation and cell death (49). Cancer can occur when the balance of cell division and cell death is disturbed, and defects in apoptosis can cause tumor pathogenesis (63). Thus, a key goal of cancer therapy is to promote the apoptosis of cancer cells without damage to normal cells (64). It has been reported that nanoparticle-mediated photothermal therapy induces apoptosis (65,66). Apoptosis is characterized by two main intrinsic and extrinsic apoptotic pathways (67). Upon exposure to external and internal stress stimuli, p53, a nuclear transcription factor, promotes apoptotic function by
the regulation of apoptotic protein expression of both extrinsic and intrinsic pathways (68). In the intrinsic pathway, p53 modulates the Bcl-2 family of proteins, including pro-apoptotic Bax and anti-apoptotic Bcl-2. The Bcl-2 protein family comprise central regulators of the intrinsic apoptotic pathway, which control cytochrome c release from the mitochondria to the cytosol and induce the activation of caspase-3 (69).

In the present study, ICG, Fe₃O₄, and ICG-conjugated Fe₃O₄ MNPs with NIR laser stimuli was determined to induce apoptotic cell death through ROS generation and photothermal effects. Intrinsic apoptotic pathways can be initiated by elevated intracellular ROS generation (70). Thus, we first evaluated ROS-mediated intrinsic apoptotic protein including Bax, Bcl-2, cytochrome c, and caspase-3 by western blotting. As depicted in Fig. 8A and B, ICG, Fe₃O₄, and ICG-conjugated Fe₃O₄ MNPs with NIR laser irradiation significantly upregulated pro-apoptotic Bax, but downregulated anti-apoptotic Bcl-2 protein expression compared with the control. Next, we confirmed that cytochrome c accumulation in the cytosolic extract was significantly increased by chemo-photothermal therapy using ICG, Fe₃O₄, and their conjugates, compared with the control. In addition, western blot analysis showed upregulation of caspase-3 activation by chemo-photothermal therapy using ICG, TMZ, Fe₃O₄, and their conjugates, as evidenced by increased caspase-3 cleavage fragments. Our data demonstrated that the combination of chemo-photothermal therapy using Fe₃O₄-TMZ-ICG MNPs notably promoted the intrinsic apoptosis-related pathway compared with ICG, TMZ, and Fe₃O₄ alone. The fold increase in Bax, cytochrome c release into the cytosol, and caspase-3 activation, and the fold decrease in Bcl-2 expression due to Fe₃O₄-TMZ-ICG MNPs was 5.79, 3.91, 4.92 and 0.16 compared with the control, respectively.
Figure 7. Photothermally-induced apoptosis analysis by flow cytometry in U-87 MG cells. (A) Representative of dot plots and (B) quantification of the apoptotic and necrotic cells in U-87 MG cells stained with Annexin V-FITC/PI double staining kit. The cells were pre-treated with different samples: No sample (control), 3.1 µg/ml of ICG, 6.6 µg/ml of TMZ, and 125 µg Fe/ml of Fe₃O₄, Fe₃O₄-ICG and Fe₃O₄-TMZ-ICG magnetic nanoparticles, before near-infrared laser exposure. After 2 h incubation, the cells were treated with or without NIR laser irradiation for 5 min (1 W/cm²) followed by further incubation for 22 h. All values were presented as the mean ± standard deviation, n=3; **P<0.01 vs. control. FITC, fluorescein isothiocyanate; ICG, indocyanine green; NIR, near-infrared; PI, propidium iodide; TMZ, temozolomide.
These results suggest that chemo-photothermal therapy exhibited notable anti-cancer effects against U-87 MG cells through stimulation of intrinsic apoptosis-related pathway.

The extrinsic pathway is initiated by the binding of an extracellular death ligand to its cell surface death receptors, and influences the activation of the death receptor FADD-caspase-8 pathway, which can directly activate caspase-3 (71). To investigate the molecular mechanism of extrinsic apoptosis in chemo-photothermal therapy using ICG, Fe₃O₄, and ICG-conjugated Fe₃O₄ MNPs, the mRNA expression of FADD and caspase-8 genes were analyzed by RT-qPCR. As shown in Fig. 9, ICG, Fe₃O₄, and ICG-conjugated Fe₃O₄ MNPs with NIR laser irradiation significantly upregulated the mRNA expression of FADD and caspase-8 compared
with the control. The combination of chemo-photothermal therapy using Fe₃O₄-TMZ-ICG MNPs resulted in markedly higher mRNA expression of FADD and caspase-8 (2.33 and 2.87-fold, respectively) compared with ICG, TMZ, and Fe₃O₄ alone. These results support the chemo-photothermal effects of Fe₃O₄-TMZ-ICG MNPs in promoting the apoptotic of U-87 MG cells via upregulation of extrinsic apoptosis-related genes. Taken together, chemo-photothermal therapy using Fe₃O₄-TMZ-ICG MNPs exhibited the most notable anti-cancer effect by inducing apoptosis through activation of the intrinsic and extrinsic pathways.

In this study, we prepared ICG- and TMZ-loaded Fe₃O₄ MNPs, and demonstrated their chemo-phototherapeutic synergistic effect against U-87 MG glioblastoma cells. The ICG-embedded Fe₃O₄ MNPs exhibited excellent photothermal effect and photostability under NIR laser irradiation. Further, TMZ- and ICG-loaded Fe₃O₄ MNPs exhibited synergistic cell cytotoxicity when applied via chemo-phototherapy. The experimental results showed that the combination of chemo-phototherapy using the Fe₃O₄-TMZ-ICG MNPs induced effective cancer cell death mediated by enhanced ROS generation, and modulated both the intrinsic and extrinsic apoptotic pathways. Therefore, our results demonstrated that the synthesized NIR-light-responsive Fe₃O₄-TMZ-ICG MNPs could be promising phototherapeutic agents for the treatment of glioblastoma.
