Abstract: We show that the type function of a space with finite asymptotic dimension estimates its Hilbert (or any $\ell^p$) compression. The method allows to obtain the lower bound of the compression of the lamplighter group $\mathbb{Z} \wr \mathbb{Z}$, which has infinite asymptotic dimension.

1. Introduction
The study of embeddings of groups into functional spaces (where Hilbert space plays a prominent role) was introduced by M. Gromov in [Gro93, Sec. 7.E]. It appeared to be a fundamental tool in geometric group theory since G. Yu proved that a group admitting a uniform embedding into a Hilbert space satisfies the Novikov Conjecture on homotopy equivariance of higher signatures [Yu00] (which was predicted by M. Gromov).

In [Gro93, p. 29] M. Gromov also introduced a large scale twin of the topological covering dimension, the asymptotic dimension. As noticed by N. Higson and J. Roe [HR00] spaces of finite asymptotic dimension have property A of G. Yu, a thus, in particular, they uniformly embed into $\ell^p$ spaces. This ideas already appear in [Yu98, Sec. 6].

In [GK04] E. Guentner and J. Kaminker initiated the study of rates of such embeddings. This topic was developed in a number of papers [AGS05, CTV05, SV06, Tes06a, Tes06b].

In this paper we provide an estimate for the compression of such an embedding (see Theorem 1.1.1) in terms of the secondary asymptotic invariant of a space with finite asymptotic dimension, the type function (see Section 3.1 for the definitions).

We will also use those estimates to get the lower bound of the compression of the lamplighter group $\mathbb{Z} \wr \mathbb{Z}$, which has infinite asymptotic dimension.

1.1. Results
The type function $D_k$ (Section 3.1, cf. [Gro93, p. 29]) of a metric space $X$ is defined as follows. $D_k(L)$ is the infimum of those $S$ such that there exist an open cover $\mathcal{U}$ of $X$ by sets of diameter almost $S$, the multiplicity of $\mathcal{U}$ is at most $k + 1$ and, for every $x \in X$, the ball $B_L(x)$ of radius $L$ around $x$ is contained in some set form $\mathcal{U}$. The space $X$ is said to have asymptotic dimension at most $k$ if $D_k(L) < \infty$ for all positive $L$.

**Theorem 1.1.1.** Let \((X, d)\) be a space of bounded geometry, asymptotic dimension at most \(k\) and type function \(D_k\). Let \(u\) be any non-decreasing function such that

\[
(1.1.2) \quad \int_c^\infty \frac{du(t)^p}{t^p} < \infty.
\]

Then there exists a Lipschitz map \(\theta: X \to L^p([c, \infty), du^p) \otimes \ell^p(X)\) such that

\[
d(x, y) \geq D_k(t) \Rightarrow ||\theta(x) - \theta(y)||_p \geq u(t).
\]

In particular, one can take \(u(t) = t \cdot (\log t)^{-\alpha/p}\) for any \(\alpha > 0\) (see Example 2.4.5). Other form of the condition (1.1.2) appears in [Tes06b] as condition \((C_p)\).

The proof of Theorem 1.1.1 will be postponed until p. 12 after Corollary 3.2.2.

If \((X, d)\) is a group with the word metric then the type function grows at least linearly since the diameter of the ball of radius \(L\) is at least \([L]\). The same is true for quasigeodesic spaces.

**Examples 1.1.3.** The class of spaces with linear type function contains trees and Lobačevskiï hyperbolic spaces [Gro93, p. 29].

Unfortunately, the most common way to show that a space has linear type function is to embed it into a product of trees and/or hyperbolic spaces. M. Bonk and O. Schramm [BS00] showed that every Gromov hyperbolic group admits a quasi-isometric embedding into a Lobačevskiï hyperbolic space. Alternatively, S. Buyalo and V. Schroeder [BS01] showed that such a group embeds quasi-isometrically in a product of a finite number of (locally finite) regular trees.

Also Coxeter groups have linear type function as they can be embedded quasi-isometrically in a product of (locally finite) regular trees [Jan02].

Another examples are amenable Baumslag-Solitare groups defined by the presentation \(BS^1_m = \langle a, t | tat^{-1} = a^m \rangle\) (where \(m > 1\) is any integer). They embed quasi-isometrically into the product of a \((m + 1)\)-valent tree and a Lobačevskiï space [FM98].

Recently, P. Nowak [Now06] found the first examples of groups with finite asymptotic dimension (even of asymptotic dimension one) with nonlinear type function.

1.2. **Acknowledgements**

The author warmly thanks Piotr Nowak and Romain Tessera for inspiring discussions. The author is also grateful to Pierre de la Harpe for hospitality during the final work on the manuscript.
1.3. Notation and preliminaries

Let \( f, g : \mathbb{R}_+ \to \mathbb{R}_+ \) be two weakly monotone functions. We write \( f \succeq g \) if there exist positive constants \( C \) and \( D \) such that \( f(t) \geq C g(Dt) \) for sufficiently large \( t > 0 \). We write \( f \sim g \) if \( f \succeq g \) and \( f \preceq g \).

If \( f \) is a non-decreasing (resp. non-increasing) positive function, then by \( f^{-1} \) we mean \( \inf f^{-1}(\cdot, \infty) \) (resp. \( \sup f^{-1}((0, t]) \)).

**Definition 1.3.1.** A metric space is said to have bounded geometry if for every \( R \geq 0 \) there exists \( C < \infty \) such that every ball of radius \( R \) contains at most \( C \) points.

Most of this work remains true for a wider class of spaces namely measure-metric spaces with bounded geometry (cf. [Tes06b]).

By \( \ell^p X \) we will denote the unit sphere in \( \ell^p X \).

2. Uniform embeddings in \( \ell^p \)-spaces

2.1. Property A and its profile

In this section we introduce a quantitative description of a Property A of G. Yu which will be subsequently used in the proof of Theorem 1.1.1. Other definitions were recently proposed by P. Nowak [Now06, Def. 3.2] and R. Tessera [Tes06b, Def. 3.1].

**Definition 2.1.1.** Let \( \xi : X \times X \to \mathbb{R} \) be a kernel. We will write \( (x, y) \mapsto \xi_x(y) \). Define

1. \( S(\xi) := \sup \{ d(x, y) : \xi_x(y) \neq 0 \} \),
2. \( \epsilon(\xi; p) := \sup \left\{ \frac{\| \xi_x - \xi_y \|_p}{d(x, y)} | x \neq y \right\} \).

**Remark 2.1.2.** A map \( \xi : X \to \ell^p(X) \) is \( \epsilon(\xi; p) \)-Lipschitz, and \( \epsilon(\xi; p) \) is the best Lipschitz constant.

**Definition 2.1.3.** For a space \( X \) define

\[ \epsilon_{X;p}(S) = \inf \{ \epsilon(\xi; p) | \xi : X \to \ell^p(X), S(\xi) \leq S \} \].

In particular, for any \( S > 0 \), it is possible to find a map \( \xi : X \to \ell^p(X) \) with \( S(\xi) \leq S \) and \( \epsilon(\xi; p) < 2\epsilon_{X;p}(S) \). Notice that \( \epsilon_{X;p} \) is a non-increasing function. We will write \( \epsilon_{X;p} =: \epsilon_p \) if it does not lead to ambiguity.

We do not recall the original definition of the property A due to G. Yu [Yu00, Def. 2.1]. Instead we give an equivalent formulation by N. Higson and J. Roe [HR00, L. 3.2].

**Definition 2.1.4.** A discrete metric space \( X \) of bounded geometry has property A if for any \( R > 0 \) and \( \epsilon > 0 \) there exists \( \xi : X \to \ell^1 X \) with \( S(\xi) < \infty \) and such that \( \| \xi_x - \xi_y \| \leq \epsilon \) provided \( d(x, y) \leq R \).

**Proposition 2.1.5.** If \( \inf_S \epsilon_{X;1}(S) = 0 \) then \( X \) has property A.

**Proof:** \( \xi : X \to \ell^1 X \) with \( S(\xi) < \infty \) and \( \epsilon(\xi; 1) = \epsilon/R \) satisfies the condition in the above definition. \( \square \)
To prove the opposite implication we need a mild assumption that the space is uniformly discrete (which can be always realized in a quasi-isometry class of the metric).

**Definition 2.1.6.** A metric space \((X, d)\) is uniformly discrete if \(0\) is an isolated value of the metric.

An example of uniformly discrete space is a vertex set of a graph (with unit length edges) with an induced metric, eg. a discrete group with a word metric.

**Proposition 2.1.7.** Assume that a uniformly discrete space \(X\) has property A. Then \(\inf_S \epsilon_{X;1}(S) = 0\).

*Proof:* By hypothesis we can find \(r > 0\) such that \(d(x, y) < r\) implies \(x = y\). Assume that \(||\xi_x - \xi_y|| \leq \epsilon \cdot r\) for \(d(x, y) \leq 2/\epsilon\). Then \(\xi: X \to \ell^1(X)\) is \(\epsilon\)-Lipschitz. \(\square\)

We are interested in asymptotic behavior of \(\epsilon_{X; p}\) (how fast it does converge to zero).

**Example 2.1.8.** Let \(V\) be a vertex set (with the induced metric) of any simplicial tree. Then \(\epsilon_{V; p}(S) \geq (2S)^{-1/p}\). Indeed, fix a point \(\omega\) in the boundary of the tree. Let \(\xi_x(y) = S^{-1/p}\) when \(y\) is at distance at most \(S\) from \(x\) in the direction of \(\omega\). Then \(\xi: V \to \ell^p(V)\) is \((2S)^{-1/p}\)-Lipschitz [DJ99].

The above estimate is sharp only for \(p = 1\). The following example shows the optimal estimate. Although it is a direct corollary of Corollary 3.2.2 in the case where the tree is uniformly locally finite (has bounded geometry), we find it instructive to do the proof by hand in full generality.

**Example 2.1.9.** Let \(V\) be a vertex set (with the induced metric) of any simplicial tree. For any \(S \geq 1\) one can construct \(\xi: V \to \ell^p(V)\) with \(S(\xi) \leq S\) and such that \(\xi\) is \(8S^{-1}\)-Lipschitz.

*Proof:* Indeed, define \(\zeta_x(z) = \max(S + 2 - |S - 2d(x, z)|, 0)\) if the geodesic ray from \(x\) towards \(\omega\) goes through \(z\) and \(\zeta_x(z) = 0\) otherwise. Then

\[
||\zeta_x||_p > \left(2 \int_0^{S/2} (2t)^p \, dt \right)^{1/p} = \left(\frac{S^{p+1}}{p+1} \right)^{1/p} = \frac{S^{1+1/p}}{(p+1)^{1/p}},
\]

and if \(d(x, y) = 1\), then \(||\zeta_x - \zeta_y||_p = 2^p(2[S/2] + 2)\). Thus \(\xi_x = \zeta_x/||\zeta_x||_p\) satisfies

\[
||\xi_x - \xi_y||_p < 2 \left(\frac{2[S/2] + 2}{S} \right)^{1/p} (1 + p)^{1/p} S^{-1} \leq 8S^{-1}
\]

for \(d(x, y) = 1\). \(\square\)
2.2. Quasi-isometry invariance

Let \( f: X \to Y \) be a map. If \( X \) and \( Y \) are equipped with metrics \( d_X \) and \( d_Y \) we define the compression \( \rho_f \) of \( f \) as the greatest non-decreasing function such that

\[
\rho_f(d_X(x, x')) \leq d_Y(f(x), f(x')).
\]

**Proposition 2.2.1.** Let \( f: X \to Y \) be a map. Then \( \varepsilon_{Y; p}(\rho_f(S)) \leq \varepsilon_{X; p}(3S) \).

**Proof:** Chose a map \( s: Y \to Y \) such that \( s(y) \in f(X) \cap B_y(2\text{dist}(y, f(X)) \). Obviously \( f(X) \cap B(y, 2\text{dist}(y, f(X)) \) is not empty. Notice that

\[
d(f(x), s(y)) \leq d(f(x), y) + d(s(y), y) \leq 3d(f(x), y)
\]

while \( d(s(y), y) \leq 2\text{dist}(f(x), y) \leq 2d(f(x), y) \). In particular, \( s(y) = y \) if \( y \in f(X) \). For \( \xi: Y \to \ell^p(Y) \) we define \( \sigma: X \to \ell^p(X) \) by the formula

\[
\sigma_x(z) := \left( \sum_{s(y) = f(z)} |\xi_{f(x)}(y)|^p \right)^{1/p}.
\]

We are left to show that

\[
||\sigma_x||_p = ||\xi_{f(x)}||_p,
\]

\[
||\sigma_x - \sigma_{x'}||_p \leq ||\xi_{f(x)} - \xi_{f(x')}||_p, \quad \text{and}
\]

\[
\rho_f(S(\sigma)) \leq 3S(\xi).
\]

Indeed,

\[
||\sigma_x||^p = \sum_{z \in X} \sum_{s(y) = f(z)} |\xi_{f(x)}(y)|^p = \sum_{y \in Y} |\xi_{f(x)}(y)|^p = ||\xi_{f(x)}||^p.
\]

\[
||\sigma_x - \sigma_{x'}||^p \leq \sum_{z \in X} \left( \sum_{s(y) = f(z)} |\xi_{f(x)}(y)|^p \right)^{1/p} - \left( \sum_{s(y) = f(z)} |\xi_{f(x')}(y)|^p \right)^{1/p}.
\]

(by triangle inequality in \( \ell^p(s^{-1} \circ f(z)) \))

\[
\rho_f(S(\sigma)) = \sup \{ \rho_f(d_X(x, z)) | \sigma_x(z) \neq 0 \}
\]

\[
\leq \sup \{ d_Y(f(x), f(z)) | \sigma_x(z) \neq 0 \}
\]

\[
\leq \sup \{ d_Y(f(x), s(y)) | \xi_{f(x)}(y) \neq 0 \}
\]

\[
\leq \sup \{ 3d_Y(f(x), y) | \xi_{f(x)}(y) \neq 0 \}
\]

\[
\leq \sup \{ 3d_Y(u, y) | \xi_{u}(y) \neq 0 \} = 3S(\xi).
\]

\[\square\]
A consequence of the previous proposition is the quasi-isometry invariance of $\epsilon_{X;p}$.

**Corollary 2.2.2.** Let $X, Y$ be metric spaces. Let $f : X \rightarrow Y$ be a quasi-isometry. Then

$$\epsilon_{X;p} \sim \epsilon_{Y;p}.$$ 

From Proposition 2.2.1 we get an immediate

**Corollary 2.2.3.** Let $X \subseteq Y$ be a subspace with the induced metric. Then

$$\epsilon_{X;p} \preceq \epsilon_{Y;p}.$$ 

### 2.3. Dependence on $p$

For the proofs of the estimates of this section the reader may consult [BL00] or easily adjust the proofs from the original paper [Maz30].

Consider a map called the Mazur map $M : \ell^q_1 X \rightarrow \ell^p_1 X$ defined by the formula

$$(Mf)(x) = |f(x)|^{q/p-1}f(x).$$

This map is $q/p$-Lipschitz if $p \leq q$. Thus we obtain

**Corollary 2.3.1.** Assume that $p \leq q$. Then

$$\epsilon_p \leq q/p \epsilon_q.$$ 

**Lemma 2.3.2.** Assume that $\epsilon_p(S) \leq \varphi(S) S^{\alpha/p}$, where $\varphi$ does not depend on $p$. Then

$$\epsilon_p(S) \leq \frac{\epsilon^\alpha}{p} \varphi(S) \log(S)$$

for $S \geq e^p$.

*Proof:* This follows from Corollary 2.3.1 by putting $q = \log S$. 

On the other hand if $p \geq q$ the Mazur map is only Hölder with exponent $p/q$.

Let us make a reasonable assumption on the metric space. We assume that there exists $M$ such that for $d$ sufficiently large there are $x, y \in X$ such that $d < d(x, y) < Md$.

Under the above assumption $\epsilon_p(S) \leq (MS)^{-1}$. Indeed if $d(x, y) > 2S$ and $S(\xi_x) \leq S$ then $\xi_x$ and $\xi_y$ have disjoint supports and $||\xi_x - \xi_y|| = 2$. Thus if $2MS > d(x, y) > 2S$ then $||\xi_x - \xi_y||/d(x, y) > (MS)^{-1}$.

Thus even if $\epsilon_1(S) \preceq S^{-1}$ (i.e. $\epsilon_1$ has the fastest possible decay) the estimate on $\epsilon_p$ coming from the Mazur map ($\epsilon_p(S) \preceq S^{-1/p}$) is usually far from sharp (cf. Examples 2.1.8 and 2.1.9).
2.4. $\ell^p$ compression

**Definition 2.4.1.** [Gro93] Let $X, Y$ be metric spaces. A map $f: X \to Y$ is a coarse embedding (uniform map) if there exist non-decreasing functions $\rho_-, \rho_+: [0, \infty) \to [0, \infty)$ satisfying

1. $\rho_-(d_X(x, y)) \leq d_Y(f(x), f(y)) \leq \rho_+(d_X(x, y))$ for all $x, y \in X$,
2. $\lim_{t \to \infty} \rho_-(t) = +\infty$.

The smallest function $\rho_+$ one can choose is called the *dilation* of $f$.

If the space $X$ is quasi-geodesic (as for example a Cayley graph of a group) then one can take $\rho_+$ to be an affine function. The main quantitative interest is how big can one choose $\rho_-$.

Hilbert space compression rate of a metric space was introduced by Guentner and Kaminker [GK04] and it is the supremum of $\alpha$ such that $X$ admits a coarse embeddings into the Hilbert space with lower bound $\rho_-(t) \geq t^\alpha$.

Below we consider embeddings in an $\ell^p$-space for any $p \geq 1$.

**Proposition 2.4.2.** Let $X$ be a metric space. Let $f: [c, \infty) \to \mathbb{R}$ be a non-decreasing left-continuous function. Assume that a measurable field of maps

$$[c, \infty) \times X \ni (S, x) \mapsto \xi^S_x \in \ell^p_X$$

satisfies $S(\xi^S_x) \leq S$ and

$$\int_c^\infty \varepsilon(\xi^S_x, p) df(S)^p =: C < \infty.$$  

Then the map $\theta(x) := \xi(x) - \xi(x_0)$ (where $x_0$ is an arbitrary reference point) is a $C^{1/p}$-Lipschitz map $X \to L^p([c, \infty), df^p) \otimes \ell^p(X)$ which compression $\rho_-$ is asymptotically bounded by $f$, more precisely

$$\rho_-(d) \geq 2f(d/2) - 2f(c).$$

**Remark 2.4.3.** One can always find $f$ piecewise constant with the same asymptotic behavior.

**Proof:** Step 1 ($\theta$ is $C$-Lipschitz) By the definition of the norm in $L^p([c, \infty), df^p) \otimes \ell^p(X)$ we have

$$||\theta(x) - \theta(y)||_p = \int_c^\infty ||\xi^S_x - \xi^S_y||_p df(S)^p \leq \left( \int_c^\infty \varepsilon(\xi^S_x, p) df(S)^p \right) d(x, y)^p = C d(x, y)^p.$$  

Step 2 (bound on the compression). Assume that $d(x, y) > d$. Since $\text{supp}(\xi^S_x) \subset B_S(x)$ we have that $||\xi^S_x - \xi^S_y||_p = 2$ if $2S \leq d$. What follows,

$$||\theta(x) - \theta(y)||_p \geq \int_c^{d/2} 2^p df(S)^p = 2^p (f(d/2)^p - f(c)^p) \geq 2^p (f(d/2) - f(c))^p.$$  

The claim follows by the continuity of $f$ from the left. □
Corollary 2.4.4. Let $X$ be a metric space. Let $f : [c, \infty) \to \mathbb{R}$ be a non-decreasing function such that
\[
\int_c^\infty \epsilon_p(S)^p \, df(S)^p < \infty.
\]
then there exist an uniform embedding $\theta : X \to L^p([c, \infty), df_p) \otimes \ell^p(X)$ such that the compression $\rho_-$ satisfies $\rho_- \succeq f$.

Proof: The assumption in Proposition 2.4.2 that $f$ is left-continuous was made only to get a precise bound on the compression. Replacing $f$ by $g(t) := \lim_{s \searrow t} f(s)$ makes the function $g$ left-continuous and does not change the value of the integral. On the other hand $f \sim g$ with constants arbitrary close to 1.

Taking sufficiently small subdivision of $[c, \infty)$ one constructs a piecewise constant (thus measurable) field $\xi$ with the property $\epsilon(\xi^S; p) < 2\epsilon_p(S)$ and $S(\xi^S) \leq S$. Thus the claim. \qed

Example 2.4.5. Let $u$ satisfy the condition
\[
\int_c^\infty \frac{du(t)^p}{t^p} < \infty.
\]
Then $f(t) := u(1/\epsilon_p(t))$ satisfies the assumption of Proposition 2.4.2. An example of such $u$ is $u(t) = t \log(t)^{(1+\alpha)/p}$ for any $\alpha > 0$. Indeed,
\[
\int_c^\infty \epsilon_p(S)^p \frac{1}{\epsilon(S)^p |\log(\epsilon_p(t))|^{1+\alpha}} = \int_{|\log \epsilon_p(c)|}^{\infty} e^{-pt} \frac{e^{pt}}{t^{1+\alpha}} = \int_{|\log \epsilon_p(c)|}^{\infty} d t^{-1-\alpha} + pt^{-1-\alpha} d t = t^{-1-\alpha} - \frac{p}{\alpha} t^{-\alpha} \bigg|_{|\log \epsilon_p(c)|}^{\infty} < \infty.
\]

2.5. Uniform embeddings of trees

Corollary 2.4.4 and Example 2.1.9 provide an embedding of a tree into $\ell^p$ space with compression bigger than given non-decreasing function $u$ satisfying $\int t^{-p} du(t)^p < \infty$.

Independently, Tessera improved [Tes06a, Thm. 7.3] the original construction of Guentner and Kaminker [GK04, Prop. 4.2] to obtain an embeddings of a trees with such an asymptotic.

On the other hand Tessera [Tes06a, Cor. 6.3] showed, that, for $2 \leq p < \infty$ and any tree $T$ with no vertices of valence 1 or 2, the compression $\rho$ of any Lipschitz map $T \to \ell^p$ satisfies $\int t^{-p} dp(t)^p < \infty$.

The difference between our construction and the construction of Guentner, Kaminker and Tessera is the following. The former is a cocycle with respect to the action of the (amenable) stabilizer of
the point in the boundary, when the latter is a cocycle with respect to the the action of the (compact) stabilizer of the vertex in the tree.

By being a cocycle we mean the following property. Let a group $\Gamma$ act on a space $X$. The action induces a representation on the space $W = \ell^p(X) \otimes L^p([c, \infty))$. The map $\theta: X \to W$ is called $\Gamma$-cocycle if $\Gamma \ni \gamma \mapsto \vartheta(\gamma) := \theta(\gamma x) - \gamma \theta(x) \in W$ is independent on $x \in X$. Moreover then $\vartheta$ satisfies the cocycle relation

$$\vartheta(\gamma \gamma') = \gamma \vartheta(\gamma') + \vartheta(\gamma),$$

or, in other words, $w \mapsto \gamma w + \vartheta(\gamma)$ is an affine isometric action of $\Gamma$ on $W$.

**Proposition 2.5.1.** Let a group $\Gamma$ acts on a space $X$. If $\xi^S: X \to \ell^p_1 X$ are $\Gamma$-equivariant then the map $\theta$ constructed in Proposition 2.4.2 is a $\Gamma$-cocycle. Moreover, $\vartheta(g) = \theta(gx_0)$ where $x_0$ is the chosen reference point.

On the other hand, assume that $\theta$ is an cocycle on the vertex set of a tree with values in a Hilbert space equivariant with respect to some group $\Gamma$, subgroup of the full automorphism group of the tree, with the compression $\rho_\theta$ satisfying $\rho(\theta) / \sqrt{t} \to \infty$. Then the group $\Gamma$ is necessarily amenable by [CTV05, Thm. 4.1] or by a small modification of [GK04, Thm. 5.3].

### 3. Spaces with finite asymptotic dimension

#### 3.1. Type function

**Definition 3.1.1.** Let $\mathcal{U}$ be a cover of $X$. Define

1. **the Lebesgue number at $x \in X$**

   $$L(\mathcal{U}, x) = \sup_{U \in \mathcal{U}} \{ r : B_r(x) \subset U \},$$

2. **the Lebesgue number of $\mathcal{U}$**

   $$L(\mathcal{U}) = \inf_{x \in X} L(\mathcal{U}, x),$$

3. **the multiplicity of $\mathcal{U}$ at $x \in X$**

   $$m(\mathcal{U}, x) = \# \{ U \in \mathcal{U} | x \in U \},$$

4. **the multiplicity of $\mathcal{U}$**

   $$m(\mathcal{U}) = \max_{x \in X} m(\mathcal{U}, x),$$

5. **the mesh of $\mathcal{U}$**

   $$S(\mathcal{U}) = \sup \{ \text{diam}(U) | U \in \mathcal{U} \}.$$

**Definition 3.1.2.** [DB05] We say that a metric space has asymptotic dimension less than $m \in \mathbb{N}$, denoted

$$\text{asdim} X < m,$$
if for every $L < \infty$ there exist a number $S < \infty$ and a cover $\mathcal{U}$ with mesh at most $S$, with multiplicity at most $m$ and Lebesgue number at least $L$.

**Definition 3.1.3.** Let $X$ be a metric space with finite asymptotic dimension. Define the type function $D_{m-1}: \mathbb{R}^+ \to \mathbb{R}^+ \cup \{\infty\}$ in the following way: $D_{m-1}(L)$ is the infimum of those $S > 0$ for which $X$ can be covered by a family of sets with mesh at most $S$, multiplicity at most $m$ and Lebesgue number at least $L$.

**Definition 3.1.4.** We also define $\delta_p(S) = \sup_{\mathcal{U}} \left\{ \frac{L(\mathcal{U})}{m(\mathcal{U})^{2/p}} \right\}$ where $\mathcal{U}$ runs over a set of covers of $X$ with mesh at most $S$.

**Remark 3.1.5.** Of course, $D_{m-1}(m^{2/p}\delta_p(S)) \geq S$ for any $m$ and $p$.

**Remark 3.1.6.** The type function was originally ([Gro93, p. 29]) defined in a different way. In the rest of this section we will compare the two definitions.

**Proposition 3.1.7.** A metric space $X$ has asymptotic dimension at most $k$ if for every $L$ there exists a cover $\mathcal{U} = \bigcup_{i=0}^{k} \mathcal{U}_i$ with finite mesh and the property, that, for any $0 \leq i \leq k$, any two different sets form $\mathcal{U}_i$ are $L$ disjoint.

**Proof:** This is a part of [DB05, Thm. 1].

The original definition of a type function, which we will call $\tilde{D}_k$, is as follows: $\tilde{D}_k(L)$ is the infimum of the mesh of the covers as in the Proposition 3.1.7. Note that $L/2$ thickening of the cover as in Proposition 3.1.7 is a cover with mesh at most $\tilde{D}_k(L) + L$ multiplicity at most $k$ and Lebesgue number at least $L/2$. Thus

$$D_k(L/2) \leq \tilde{D}_k(L) + L.$$

We leave it as an easy exercise to show that if the space is the vertex set of a graph (with unit length edges) with the induced metric, then $\tilde{D}_k(L) \geq L/k - 1$. More generally, the inequality $\tilde{D}_k(L) \geq L$ holds for quasi geodesic spaces. For such spaces $D_k \leq \tilde{D}_k$ and Theorem 1.1.1 remains true if one replaces $D_k$ by $\tilde{D}_k$.

### 3.2. Asymptotic dimension and Property A

In this section we will exhibit a link between $\epsilon_p$ and asymptotic dimension of $X$, in particular we will show that a large class of spaces, namely the spaces with finite asymptotic dimension of linear type, satisfy $\epsilon_{X;p}(S) \sim S^{-1}$ for all $p \geq 1$.

**Theorem 3.2.1.** Let $\mathcal{U}$ be a cover of $X$ with finite multiplicity. Then there exist a map $\xi: X \to \ell^p X$ which is $2\sqrt{2m(\mathcal{U})^2/L(\mathcal{U})^{2/p}}$-Lipschitz and satisfies $S(\xi) = S(\mathcal{U})$.

**Proof:** Let $\mathcal{U}$ be a cover of $X$. For any $\mathcal{U} \in \mathcal{U}$ define

$$\psi_{\mathcal{U}}(x) = \text{dist}(x, X - \mathcal{U}),$$

$$\psi(x) = \left( \sum_{\mathcal{U} \in \mathcal{U}} \psi_{\mathcal{U}}(x)^p \right)^{1/p}.$$
We have
\[
\psi(x) \geq L(\Omega, x) \geq L(\Omega),
\]
and
\[
\psi_U \text{ is } 1\text{-Lipschitz, i.e. } |\psi_U(x) - \psi_U(y)| \leq d(x, y).
\]

**Claim:**

\[
\left| \frac{\psi_U(x)}{\psi(x)} - \frac{\psi_U(y)}{\psi(y)} \right| \leq 2 \frac{(m(\Omega) + 1/2)^{1/p}}{L(\Omega)} d(x, y).
\]

Indeed,

\[
\left| \frac{\psi_U(x)}{\psi(x)} - \frac{\psi_U(y)}{\psi(y)} \right|^p = \left| \frac{\psi_U(x) - \psi_U(y)}{\psi(x)} - \frac{\psi_U(y)}{\psi(y)} \cdot \frac{\psi(x) - \psi(y)}{\psi(x)} \right|^p
\]
(by the inequality between the arithmetic and p-mean)

\[
\leq 2^{p-1} \left( \left| \frac{\psi_U(x) - \psi_U(y)}{\psi(x)^p} \right|^p + \frac{\psi_U(y)^p}{\psi(y)^p} \cdot \left| \frac{\psi(x) - \psi(y)}{\psi(x)^p} \right|^p \right)
\]
(by the triangle inequality in \(L^p(\Omega)\) and \(\psi_U(y) \leq \psi(y)\))

\[
\leq 2^{p-1} \frac{\psi(x)^p}{\psi(x)^p} \left( |\psi_U(x) - \psi_U(y)|^p + \sum_{V \in \Omega} |\psi_V(x) - \psi_V(y)|^p \right).
\]

\[
\leq 2^{p-1} \frac{1 + 2m(\Omega)}{L(\Omega)^p} d(x, y)^p.
\]

Let \(\phi_U(x) = \psi_U(x)/\psi(x)\) and \(\chi_U = \psi_U/||\psi_U||_p\). Define

\[
\xi_x(z) := \left( \sum_{U \in \Omega} \phi_U(x)^p \chi_U(z)^p \right)^{1/p}.
\]

Note that \(\chi_U\) and \(\xi_x\) are well defined. The support of \(\psi_U\) is contained in a ball of radius \(S\), thus the norm reduces to the finite sum. Also the sum in the definition of \(\xi_x(z)\) runs over those \(U\) which contain both \(x\) and \(z\), thus at most \(m(\Omega)\) of them. In particular, \(\xi_x(z) \neq 0\) if and only if \(x\) and \(z\) belong simultaneously to at least one \(U \in \Omega\). Therefore \(S(\xi) = S(\Omega)\).

Moreover, \(||\xi_x||_p^p = \sum_{z \in X} \sum_{U \in \Omega} \phi_U(x)^p \chi_U(z)^p = \sum_{U \in \Omega} \phi_U(x)^p (\sum_{z \in U} \chi_U(z)^p) = 1\).

We are left to check the Lipschitz condition. If \(d(x, y) \geq L(\Omega)\), the condition is trivial as \(||\xi_x - \xi_y|| \leq ||\xi_x|| + ||\xi_y|| = 2\) for all \(x\) and \(y\). Therefore assume that \(d(x, y) < L(\Omega)\), and, in particular, there is a set in \(\Omega\) containing both \(x\) and \(y\). Thus, there are at most \(2m(\Omega) - 1\) sets
containing any of $x$ or $z$. As previously we check:

$$
||\xi_x - \xi_y||_p^p = \sum_{z \in X} \left| \left( \sum_{U \in \mathcal{U}} (\phi_U(x) \chi_U(z))^p \right)^{1/p} - \left( \sum_{U \in \mathcal{U}} (\phi_U(y) \chi_U(z))^p \right)^{1/p} \right|^p
$$

(by triangle inequality in $\ell^p(\mathcal{U})$)

$$
\leq \sum_{z \in X} \sum_{U \in \mathcal{U}} |\phi_U(x) \chi_U(z) - \phi_U(y) \chi_U(z)|^p
$$

$$
= \sum_{U \in \mathcal{U}} |\phi_U(x) - \phi_U(y)|^p \left( \sum_{z \in U} \chi_U(z)^p \right)
$$

(by the Claim)

$$
\leq \sum_{x \text{ or } y \in \mathcal{U} \in \mathcal{U}} 2^{-1} (2m(\mathcal{U}) + 1) \left( \frac{2d(x,y)}{L(\mathcal{U})} \right)^p
$$

$$
= 2^{-1} (2m(\mathcal{U}) - 1)(2m(\mathcal{U}) + 1) \left( \frac{2d(x,y)}{L(\mathcal{U})} \right)^p \leq 2m(\mathcal{U})^2 \left( \frac{2d(x,y)}{L(\mathcal{U})} \right)^p.
$$

and, in particular, $\xi: X \to \ell^p(\mathcal{U})$ is $2(2m(\mathcal{U})^2)^{1/p}L(\mathcal{U})^{-1}$-Lipschitz.

The proof of Theorem 3.2.1 depends on an informal argument of Higson and Roe [HR00] and more precisely on a computation from the proof of Theorem 1 form [DB05] (case $p = 1$ of Theorem 3.2.1).

**Corollary 3.2.2.** Let $X$ be a metric space with finite asymptotic dimension and $\delta$-function $\delta_p$ (see Definition 3.1.4). Then

$$
\varepsilon_p \leq \frac{2^{1+1/p}}{\delta_p} \leq \frac{4}{\delta_p}
$$

for all $1 \leq p < \infty$.

**Proof of Theorem 1.1.1:** Substitute $f := u \circ D_k^{-1}$ in Corollary 2.4.4. The claim follows from inequalities

$$
4/\varepsilon_p \geq \delta_p \geq k^{-2/p} D_k^{-1},
$$

due to Remark 3.1.5 and Corollary 3.2.2.

A. N. Dranishnikov [Dra04] defined groups with a polynomial dimension growth. In term of the function $\delta_p$ it is defined as follows

**Definition 3.2.3.** A space has polynomial dimension growth of degree less than $k$ if $\lim_{S \to \infty} \delta_{2k}(S) = \infty$.

A straightforward corollary from Corollary 3.2.2 and Proposition 2.1.5 is

**Corollary 3.2.4.** [Dra04, Thm. 3.3] A space with a polynomial dimension growth has property A.

**Example 3.2.5.** A space $X$ is said to have polynomial growth if there exist $C$ and $n$ such that every ball of radius $R$ contains at most $C \cdot R^n$ elements. Take a cover of $X$ by all balls of radius
S/2. Its mesh is at most S, Lebesgue number is S/2 and multiplicity is C \cdot (S/2)^n. Thus \( \delta_p(S) \geq \frac{2^{2/p-1}}{C^{2/p}} S^{1-2n/p} \). In particular, by Corollary 3.2.2 \( e_p(S) \leq 4C^2 S^{-1+2n/p} \), and by Lemma 2.3.2, \( e_p(S) \leq (4e^2nC^2p^{-1}) \log(S)/S \) for \( S \geq e^p \), and the \( \ell^p \) compression rate for such a space equals one.

4. Application to spaces with infinite asymptotic dimension

4.1. Preliminaries

Let \( A^{n-1} = \{ x = (x_1, \ldots, x_n) \in \mathbb{R}^n | \sum_{i=1}^n x_i = 0 \} \). Equip \( A^{n-1} \) with a norm \( ||x|| := \sum_{i=1}^n |x_i| \). For any \( I \subset \{1, \ldots, n\} \) define a functional

\[
\phi_I(x) := \sum_{i \in I} x_i \#I - \sum_{i \notin I} x_i \#I^c = \frac{n \sum_{i \in I} x_i}{\#I \cdot \#I^c}.
\]

Where \( I^c \) denotes the complement of \( I \). Note that \( \phi_I = -\phi_{I^c} \).

Remark 4.1.1. For any \( I \) we have \( ||x|| > \phi_I(x) \).

Let

\[
V := \left\{ x \in A^{n-1} | \phi_I(x) \leq \frac{1}{2} \text{ for all } I \right\}.
\]

Let

\[
[i]_j := \begin{cases} i - n & \text{if } j \leq i, \\ i & \text{if } j > i. \\ \end{cases}
\]

Define \( \Lambda := \{ A^{n-1} \cap \mathbb{Z}^n \} \). Let \( \mathcal{U}_I := \{ [i] + x + V | x \in \Lambda \} \).

Lemma 4.1.2. \( \mathcal{U} := \bigcup_{i=0}^{n-1} \mathcal{U}_i \) is a (closed) cover of \( A^{n-1} \).

Proof: Put for the moment auxiliary \( l^2 \)-norm, defined by \( ||x||_2 = \sqrt{\sum_{i=1}^n |x_i|^2} \), on \( A^{n-1} \).

Below we will just check that \( V \) consists of the points that are closer or at the same distance to 0 than any vector \([i]\) or its image by the action of the permutation group \( S_n \), which is enough to conclude the claim.

Indeed, the set of points which are closer or at the same distance to 0 than to \([i]\) is defined by the inequality

\[
\langle x|[i] \rangle \leq 1/2 ||[i]||_2^2,
\]

where \( \langle \cdot | \cdot \rangle \) is the scalar product associated to \( || \cdot ||_2 \).

Straightforward computation shows, that (4.1.3) is equivalent to \( \phi_{\{1, \ldots, i\}}(x) \leq 1/2 \).

One can prove a stronger statement, namely that \( V \) is the Voronoi cell of the lattice \( \bigcup_{i=0}^{n-1} \Lambda + [i] \) [CS99, Ch. 6.6 and 21.3.B].
Lemma 4.1.4. Each $U_i$ consists of $1/(n-1)$-disjoint sets.

Proof: Let $x$ and $x'$ be two different points in $[i] + \Lambda$. Chose $i_0$ such that $x_{i_0} > x'_{i_0}$. Let $I = \{i_0\}$. Then

$$\phi_I(x - x') \geq \frac{n(x_{i_0} - x'_{i_0})}{1 \cdot (n-1)} \geq \frac{n}{(n-1)}.$$  

Let $z \in x + V$ and $z' \in x' + V$. Then

$$||z - z'|| \geq \phi_I(z - z') \geq \phi_I(x - x') - \phi_I(z - x) + \phi_I(z' - x') \geq \frac{n}{n-1} - \frac{1}{2} - \frac{1}{2} = \frac{1}{n-1}$$

by Remark 4.1.1.

Question 4.1.5. What is the best estimate for disjointness?

The set of extremal points (the vertices) of $V$ is the orbit of $\sigma = (2n)^{-1}(1-n, 3-n, \ldots, n-1)$ under the permutations of coordinates [CS99, Ch. 6.6 and 21.3.B]. From now on assume that $n = 2k$ is even. Then $||\sigma|| = (4k)^{-1} \cdot 2 \sum_{i=1}^{k} (2i - 1) = k/2$.

Thus we have proved

Lemma 4.1.6. The $\frac{1}{2k-1}$ open thickening $U'$ of $U$ satisfies $L(U') \geq \frac{1}{2k-1}$, $S(U') = k + 1/(2k-1)$ and $m(U'_k) = 2k$.

Corollary 4.1.7. $D_{2k;Z^k}(L) \leq (2k^2 - 2k + 1)L$.

Proof: Observe that the map $\iota: Z^k \ni (\ldots, z_m, \ldots) \mapsto (1/2)(\ldots, z_m, -z_m, \ldots) \in A_{2k-1}$ is an isometry. Thus the induced cover $\iota^*U'$ satisfies the inequality of the claim for $L = \frac{1}{2k-1}$.

Since we can precompose $\iota$ with a homotety of $A_{n-1}$ the claim is true for arbitrary $L$.

Question 4.1.8. What is the rate of $D_{k;Z^k}$? Can one replace a square in $D_{2k;Z^k}(L) \leq 2k^2$ by some lower power? What about the estimates for $D_{m^\alpha}$?

One can adjust the results of the next section to prove that if $D_{cm^\alpha;Z^m} \leq Cm^\beta$ then $\epsilon_p;Z;Z \leq \log(S)/\sqrt[1+\beta]{S}$ and, what follows, the compression rate of $Z \bowtie Z$ is at least $1/(1+\beta)$. On the other hand G. Arzhantseva, V. Guba and M. Sapir [AGS05, Thm. 1.8] showed that the Hilbert compression rate of $Z \bowtie Z$ is at most 3/4. It follows that $D_{cm^\alpha}(L) \leq m^\beta \cdot L$ is impossible with $\beta < 1/3$. Thus the answer to Question 4.1.8 is nontrivial.
4.2. The Lamplighter group \( \mathbb{Z} \wr \mathbb{Z} \)

The lamplighter group is the (restricted) wreath product \( \mathbb{Z} \wr \mathbb{Z} \), where \( H \wr G \) is defined as a semidirect product \( \bigoplus_G H \rtimes G \), where \( G \) acts on \( \bigoplus_G H \) permuting the factors. In other word

\[
H \wr G = \langle H, G | [a, [b, g]] = [a, b], \quad a, b \in H, \quad g \in G - \{e\} \rangle.
\]

**Proposition** [Dra04, Prop 4.2] 4.2.1. Let \( K \) be a normal subgroup of \( G \). Let \( G \) be equipped with a (left invariant) metric. Put on \( K \) the restricted metric, and induce the metric on \( H = G/K \). Let \( k \) and \( h \) be two integers. Then

\[
D_{kh^{-1}; G}(L) \leq \frac{A}{3} D_{k-1; K}(6 D_{h^{-1}; H}(L)).
\]

In our case \( G = \mathbb{Z} \wr \mathbb{Z} \) and \( H = \mathbb{Z} \). Thus \( D_{2k-1; G}(L) \leq 4/3D_{k-1; K}(24L) \), where \( K = \bigoplus_Z \mathbb{Z} \) with the restricted metric \( d_K \). This translates to the following statement. Given a cover \( \mathcal{U} \) of \( K \) one constructs a cover \( \mathcal{W} \) of \( \mathbb{Z} \wr \mathbb{Z} \) such that \( L(\mathcal{W}) \geq L(\mathcal{U}) \), \( S(\mathcal{W}) \leq 4/3S(\mathcal{U}) \) and \( m(\mathcal{W}) \leq 2m(\mathcal{U}) \).

Following Dranishnikov [Dra04] we decompose \( K := \bigoplus_Z \mathbb{Z} = K_m \oplus K^m \), where \( K_m = \bigoplus \{ -m+1, -m+2, \ldots, -m \} \mathbb{Z} \) and \( K^m = \bigoplus \{ -m-1, -m, m+1, \ldots \} \mathbb{Z} \).

**Lemma 4.2.2.** Let \( K/K_m \ni \alpha \to g_\alpha \in K \) be a section and let \( \mathcal{W} \) be a cover of \( K_m \) then \( \bar{\mathcal{W}} := \bigcup_\alpha g_\alpha \mathcal{W} \) is a cover of \( K \) with the same mesh and multiplicity. Moreover \( L(\bar{\mathcal{W}}) = \min \{ L(\mathcal{W}), 2m+1 \} \).

**Proof:** Observe that any two cosets of \( K_m \) are at least \( 2m+1 \) apart. \( \square \)

**Proposition 4.2.3.** Let \( f: (G, d) \to (G', d') \) be a map, and \( \mathcal{U} \) be a covering of \( G' \) then

\[
\rho_+(L(f^*\mathcal{U})) \geq L(\mathcal{U}), \quad \rho_-(S(f^*\mathcal{U})) \leq S(\mathcal{U}),
\]

where \( f^*\mathcal{U} = \{ f^{-1}U | U \in \mathcal{U} \} \) is the induced cover of \( G \), and \( \rho_\pm \) are the compression and dilation of \( f \).

**Lemma 4.2.4.** The natural homomorphism \( j : K_m \to \mathbb{Z}^{2m-1} \) satisfies

\[
d_K(x, y) - 4(m - 1) \leq d_1(f(x), f(y)) \leq d_K(x, y).
\]

**Proof:** Recall ([CT05]) that if \( f: \mathbb{Z} \to \mathbb{Z} \) is an element of \( K \) (i.e. if \( f \) has finite support) then the length of \( f \) (with respect to the metric restricted from \( \mathbb{Z} \wr \mathbb{Z} \)) equals to

\[
2 \max(\{0\} \cup \{k | f(k) \neq 0\}) + 2 \max(\{0\} \cup \{-k | f(k) \neq 0\}) + \sum_{k \in \mathbb{Z}} |f(k)|.
\]

\( \square \)

**Corollary 4.2.5.** There exist a cover \( \mathcal{W} \) of \( K_m \) satisfying \( L(\mathcal{W}) \geq 2m \), \( S(\mathcal{W}) \leq 16m^3 \) and \( m(\mathcal{W}) \leq 4m \).

**Proof:** By Corollary 4.1.7 and the previous Lemma we may construct a cover of \( K_m \) satisfying the bounds. The bound on mesh follows from

\[
S(\mathcal{W}) \leq D_{4m; \mathbb{Z}^2 m}(2m) + 4(m - 1) \leq (2(2m)^2 - 2(2m) + 1) \cdot (2m) + 4(m - 1) \leq 16m^3.
\]

\( \square \)
Let \( m = 12L \). By the result of Dranishnikov, we construct a cover \( \mathcal{W} \) of \( \mathbb{Z} \wr \mathbb{Z} \) with the properties
\[
L(\mathcal{W}) \geq \frac{1}{24} \cdot 2 \cdot 12L = L, \quad S(\mathcal{W}) \leq 4/3 \cdot 16(12L)^3 = 36864L^3 \quad \text{and} \quad m(\mathcal{W}) \leq 2 \cdot 4 \cdot 12L = 96L.
\]

**Corollary 4.2.6.** \( \delta_{p;\mathbb{Z} \wr \mathbb{Z}}(S) \geq (96)^{-2/p} \left[ \sqrt[3]{S/36864} \right]^{1-2/p} \geq (1/C)S^{1/3-2/(3p)} \).

**Corollary 4.2.7.** \( \epsilon_{p;\mathbb{Z} \wr \mathbb{Z}}(S) \leq \log(S)/\sqrt[3]{S} \) for any \( 1 \leq p < \infty \).

*Proof:* This follows from Corollary 3.2.2 and Lemma 2.3.2  \( \square \)

**Corollary 4.2.8.** The \( \ell^p \) compression rate of Guentner and Kaminker of \( \mathbb{Z} \wr \mathbb{Z} \) is at least \( 1/3 \) for all \( 1 \leq p < \infty \).

**Remark 4.2.9.** This result is not sharp. For \( p = 2 \) (Hilbert compression) by other techniques G. Arzhantseva, V. Guba and M. Sapir [AGS05, Thm. 1.8] and independently Y. Stalder and A. Valette [SV06, Cor. 4.5a] showed that the compression rate is at least \( 1/2 \). Recently R. Tessera showed that the Hilbert compression rate is at least \( 2/3 \) [Tes06a, Cor. 15].

On the other hand P. Nowak showed [Now06, Cor. 4.4] that \( \epsilon_{1;\mathbb{Z} \wr \mathbb{Z}} \sim S^{-1} \), thus the \( \ell^1 \) compression rate of \( \mathbb{Z} \wr \mathbb{Z} \) is one. By the H"older property of the Mazur map the \( \ell^p \)-compression rate is at least \( 1/p \), which gives better estimate that Corollary 4.2.8 for \( 1 \leq p < 3 \).
