Visualization of the contribution of each herb to the formula and ELSD filtering

These are additional figures for sections 2.2. and 2.3.

**Supplementary Figure 1:** Visualization of the contribution of the ten herbs to the formula, in which each herb is represented by a different color: A) 2D feature map in NI: each black circle represents a feature detected in the formula, the size of the circles is fixed and equal for all features. The inner color of the circle indicates that the feature is specifically detected in one of the ten herbs (90% specificity threshold). B) FBMN in NI for the organization of the MS/MS spectra of all features presented in A, which the same color coding and fixed node size.
Supplementary Figure 2: A) 2D feature map of HRMS processed data in negative ionization, B) ELSD profiling of the formula, C) and D) bar plot with superimposed ELSD area of the single herb extracts adjusted to their proportion into the formula, divided into high (C) and low areas (D). E) 2D feature map (NI) with attributed ELSD areas. Dots with black circle represents the components that were further identified.
Supplementary Figure 3: Visualization of the ELSD detected peaks in the FBMN-NI. Each herb is represented by a different color, the size of the node is proportional to ELSD areas. See table 2 for the name of the components.

**Supplementary Figure 4:** Main steps of the script developed to express numerically the specificity of nodes and clusters. The *specificity percentage* is the relative height intensity of one feature in a multi-herb formula. The peak height of one aligned feature in one herb is divided by the sum of the heights in all herbs. The *cluster specificity percentage* is the average of the specificity percentages of the features grouped in a cluster for a given herb. A component index is a number that designates a cluster in GNPS terminology.

5 Detailed annotations of the specific and abundant components

5.1 Annotation workflow

For the features selected by ELSD filtering, their ISDB annotations obtained in the FBMN were verified and completed in detail. The annotation strategy combined MF assignment with taxonomic data since most of the constituting herbs were rather well documented from a phytochemical point of view. HRMS/MS and UV spectra were used for checking annotation consistency (Main text Fig. 1.6 and Suppl. Mat. Fig.5). The number of potential structures for the MF retrieved from HRMS data were reduced by applying a taxonomic filter (from the species to the family taxa level) (Suppl. Mat. Fig. 5). The annotation consistency was checked between the hits obtained by MF assignment from HRMS and filtering by taxonomy and ISDB spectral scoring (Top 6 hits) (Suppl. Mat. Fig. 5). When necessary, UV spectra were used as orthogonal information to confirm or discriminate the classes of compounds. Finally, a comparison with the markers referenced in the European and Chinese Pharmacopoeias was performed. Three detailed examples of this annotation process are presented in Suppl. Mat. Fig. 6 to 8. The annotation presented below were obtained from a first batch of metabolites profiling (data not shown). This workflow resulted in the thorough annotation of 22 potential markers among the features selected by ELSD, which included between 2 to 4 potential markers per herb, at the exception of Angelica sinensis for which no ELSD peak were detected. The combination of MF assignment, taxonomic filter, MS/MS scoring and orthogonal UV check provided in half of the cases a single highly probable structure, and in the other half up to 4 putative structures belonging to the same chemical class of components (Suppl. Mat., Table S1). Interestingly, the results of the taxonomic filtering and ISDB annotations were consistent in 80% of cases. Furthermore, orthogonal control by UV spectra permitted the discrimination of all annotated structures belonging to more than one class of compounds even after taxonomic filtering. Finally, the verification of the annotations against the Pharmacopoeias permitted to discriminate between 2 annotations and to modify a case.
Supplementary Figure 11: scheme of the annotation strategy.
5.2 Example of annotations

Supplementary Figure 12: annotation scheme for G2, (formally identified as liquiritin apioside): for G2 molecular formula, the DNP listed 4 possible structures for the species, three of which were proposed by the ISDB consultation. Among them, the UV spectrum eliminated the chalcone, resulting in two possible structures of the same chemical class at the end of the annotation.
Supplementary Figure 13: annotation scheme for SC1 (baicalin): this component was classified as a trihydroxyflavone by taxonomy (6 genus hits), four of which were then proposed by ISDB consultation. Among the 4 final hits, the most relevant was baicalin, which is the marker of both European and Chinese Pharmacopoeias.
Supplementary Figure 14: annotation schema for SM1 (astilbin): no match between taxonomy and ISDB was found. The ISDB consultation retrieved 3 classes of compounds. UV spectrum discriminated them by demonstrating the presence of flavanone and discarding the chalcones and xanthones. If no concordant taxonomical hit was retrieved by the ISDB consultation, three pentahydroxyflavanones were suggested. The consultation of the Chinese Pharmacopoeia (CP) permitted to discriminate between them and to select the official marker, astilbin, which is not referenced in the DNP for *S. glabra*. 
### 5.3 Summary of annotations

8 Multi-component signatures

Supplementary Figure 15: multi-component signatures in NI: A) metabolite profile of the formula showing all formally identified components. B) metabolite profile of the formula showing some of the selected multi-component signatures. C) multicomponent signatures for *I. tinctoria* and its marker isovitexin (I1), *P. cuspidatum* and *E*-piceid (PO1), *P. vulgaris* and rosmarinic acid (PR1) and *C. indicum* and C1. D) C)
multicomponent signatures for *S.baicalensis* and wogonoside and oroxyloside (SC2 and SC3), and for *O.diffusa*. See table S3 to S12 for annotations.

**Supplementary Figure 16:** representation of clusters from the FBMN-PI in relation to the chromatogram of the formula: A) UHPLC-HRMS metabolite profile of the formula in PI, B) cluster containing potential co-markers for *G.uralensis*, the color tones of the nodes indicate the features with the same retention time, C) bar plot showing the peak height intensity of related clusters, D) cluster with potential co-markers for *S.glabra*, E)
cluster with potential co-markers for *A. sinensis*, F) cluster with potential co-markers for *S. flavescens*, the color tones of the nodes indicate the features with the same retention time. The numbers indicate the m/z ratio of the nodes, followed by their retention time. See table S3, S5, S11 and S12 for related annotation. G) FBMN. See Fig.4 for the node layout legends.

**Supplementary Figure 17:** representation of a cluster from the FBMN-NI in relation to the chromatogram of the formula: A) UHPLC-HRMS metabolite profile of the formula in NI, B) bar plot showing the peak height intensity of related cluster, which contains potential co-markers for *S. baicalensis* and *P. cuspidatum*. The numbers indicate the m/z ratio of the nodes, followed by their retention time. See table S8 and S10 for related annotation. See Fig.4D for the node layout legends.
Supplementary Figure 18: representation of a cluster from the FBMN-PI in relation to the chromatogram of the formula: A) UHPLC-HRMS/MS metabolite profile of the formula in PI, B) cluster with potential co-markers for *O. diffusa* and the corresponding histogram of the node peak heights as a function of time. The numbers indicate the m/z ratio of the nodes, followed by their retention time. See table S7 for related annotation. See Fig. 4D for the node layout legends.
Supplementary Figure 19: representation of a cluster from the FBMN in NI in relation to the chromatogram of the formula: A) UHPLC-HRMS/MS metabolite profile of the formula in NI, B) cluster with potential co-markers for *P. vulgaris* and *S. flavescens*, C) bar plot showing the peak heights of related nodes in the cluster, D) cluster with potential co-markers for *C. indicum*, E) cluster with potential co-markers for *S. baicalensis*. The
numbers on the nodes indicate the \( m/z \) ratio of the nodes, followed by their retention time. See table S4, S8, S8 and S9 for related annotation. See Fig. 4D for the node layout legends.

9 UHPLC-UV-PDA HRMS/MS data acquisition

The analyses were performed on an Acquity UPLC system interfaced to an Orbitrap Q-Exactive Focus mass spectrometer (Thermo Scientific) using a heated electrospray ionization (HESI-II) source and an Acquity UPLC PDA detector. Thermo Scientific Xcalibur 2.1 software was employed for instrument control. PDA detector recorded from 210 to 450 nm (resolution 1.2 nm). The optimized HESI-II parameters were as follows: source voltage, 3.5 kV (PI), 2.5 kV(NI); sheath gas flow rate (N2), 47.5 units; auxiliary gas flow rate, 11.25 units; spare gas flow rate, 2.25; capillary temperature, 256.25°C, S-Lens RF Level, 45. The mass analyzer was calibrated using a mixture of caffeine, methionine–arginine–phenylalanine–alanine–acetate (MRFA), sodium dodecyl sulfate, sodium taurocholate, and Ultramark 1621 in an acetonitrile/methanol/ water solution containing 1% formic acid by direct injection. The data-dependent MS/MS events were performed on the three most intense ions detected in full scan MS (Top3 experiment). The MS/MS isolation window width was 1 Da, and the stepped normalized collision energy (NCE) was set to 15, 30 and 45 units. In data-dependent MS/MS experiments, full scans were acquired at a resolution of 35,000 FWHM (at \( m/z \) 200) and MS/MS scans at 17,500 FWHM both with an automatically determined maximum injection time. After being acquired in a MS/MS scan, parent ions were placed in a dynamic exclusion list for 2.0 s
