CONCLUSION
Based on the pattern of gonadosomatic index, it was concluded that this fish has a prolonged active reproductive period. Their reproduction in this basin shows some differences from other reports, which might be related to different environmental conditions.

Keywords: gonadosomatic index, oocyte diameter, ovary, spawning, loach

INTRODUCTION
The cobitid fishes are represented in Iran by Cobitis linea (Heckel, 1847) and another not clearly identified species, occurring south of the Caspian Sea basin. Some authors reported the latter fish as Cobitis taenia Linnaeus, 1758 (see Coad 2008, Abdoli and Nädert 2009) whereas some other researchers disagreed owing the fact that Cobitis taenia is rather a north-European species and its occurrence in the southern Caspian Sea basin would be unlikely (Kottelat and Freyhof 2007). It is possible that the cobitid fish occurring at latter location might represent a new species. Therefore, for the purpose of this paper, the south Caspian loach in question will be referred to as Cobitis sp.

The earlier mentioned Cobitis linea can be found in the Kor River basin and the upper Kul River drainage of the Hormozgan basin (Banarescu and Nalbant 1966, Bianco and Nalbant 1980). Southern Caspian Sea loach...
**MATERIALS AND METHODS**

**Study area, sampling, and habitat.** The study was conducted in the Babolrud River (lat 36°26′ N, long 52°35′ E) in south of the Caspian Sea basin, north of Iran. Fish were collected from this river monthly from May 2009 to April 2010 by electrofishing (200–300 V). The water temperature of the samples site was measured simultaneously. This fish, *Cobitis* sp., is commonly found in tributary streams of the Babolrud River. The bottom of these water bodies is generally sandy with occasional silt and pebbles (5–30 cm in diameter), and the water is clear and slow running. The analysis of water at two different stations in May showed that the temperature was 19.1–20.2°C; pH 6.9–7.0, O₂ 5–9 mg · L⁻¹, and the water hardness 224 mg · L⁻¹.

**Biometry and data analysis.** The fish were measured (total length = TL; standard length = SL) to the nearest 0.1 mm and weighed (body weight = Wₗ); to the nearest 0.01 g. The gonads were weighed (gonad weight = Wₕ) to the nearest 0.001 g. To examine the monthly changes in gonads as a mean for estimating the spawning season of this loach: gonadosomatic index (GSI) and modified gonadosomatic index (MGSI) were calculated following the formulas: 

\[ GSI = \left( \frac{W_h}{W_b} \right) \times 100 \]

\[ MGSI = \left( \frac{W_h}{W_b} \right) \times 100 \]  

(Nikolsky 1963).

Altogether, the absolute fecundity (Fₘ) was estimated in 30 ovaries by calculating the number of oocytes with a diameter greater than 0.2 mm (Kostrzewa et al. 2003). To achieve accurate results: fish that were caught in the beginning of May and June 2009 and in 6 May 2010 (before spawning), were used. The relative fecundity (Fₚ) was expressed as the absolute fecundity (Fₘ) dividing by the fish body weight. The result was the number of eggs per 1 g of body weight (Bagenal 1967). To determine the oocyte diameter, the ovaries were preserved in 10% formalin solution. The diameters of 60 ova of each female fish were measured using a Zeiss SV 6 dissecting microscope outfitted with an ocular micrometer. The sex was determined based on the presence or absence of the Canestrini scale (*lamina cribrosa* i.e., a plate-like ossified extension of the ray—a secondary sexual character of males; Canestrini 1871) and the examinations of gonad morphology after dissection. The Chi square test was used to assess sex ratio deviation from a 50:50 (Wootton 1998). The fish were ageing according to scales taken from the left side of the body, between end of the pectoral fin and the beginning of the dorsal fin. In order to compare significant differences in the GSI index between samples taken on various months and various size samples, the analysis of variance (ANOVA I) was applied. The relation between the absolute fecundity (Fₘ) and body length and weight, the gonad weight and the age of females was determined by regression analysis. The data were analyzed with the SPSS version 10.0 software and Microsoft Excel 2007 spreadsheet.

**RESULTS**

**Size, sex ratio, and age.** During this study, 226 specimens of *Cobitis* sp. were caught, ranging in total length from 31.1 to 92.5 mm, standard length from 26.7 to 83.2 mm, and total weight from 0.4 to 6.2 g. The females were longer, heavier, and achieved maturity later (at the age of 2+) than the males. Their TL exceeded 45 mm and the body weight approximated 2 g. This population of loach had a narrow age range (1+ to 5+ years). The majority of the fish caught were 2+ and 3+ years old, some were 1+

| Age | n | SL [mm] | TL [mm] | Wₗ [g] |
|-----|---|---------|---------|-------|
| M   | F | M       | F       | M     | F     |
| 1+  | 10| 28.93 ± 1.86 | 29.24 ± 3.46 | 33.25 ± 2.18 | 33.07 ± 4.25 |
| 2+  | 51| 41.17 ± 4.12 | 37.69 ± 5.08 | 47.76 ± 4.95 | 46.19 ± 5.74 |
| 3+  | 36| 48.35 ± 1.74 | 48.96 ± 3.69 | 56.28 ± 2.49 | 55.81 ± 4.55 |
| 4+  | 0 | —       | 65.83 ± 3.94 | —     | 75.23 ± 4.72 |
| 5+  | 0 | —       | 75.91 ± 1.08 | —     | 87.34 ± 2.11 |

SL = standard length; TL = total length; Wₗ = body weight; n = number of specimens; SD = standard deviation; M = male; F = female.

| SL = standard length; TL = total length; Wₗ = body weight; n = number of specimens; SD = standard deviation; M = male; F = female.

---

Table 1

Length and weight (mean ± SD) in different age groups of males and females of *Cobitis* sp. from the Babolrud River
and 4+ and only a few of them were 5+ years old. The oldest females (1.77%) among specimens were 5 years old but most of them (40.71%) were in third year (+2) of their lives (Table 1). The body length increased proportionally to the age. The older loaches were longer than those which had just reached sexual maturity (in the second and third year of life). The body weight of the older fish was heavier than the young ones. Of the total number of 226 fish specimens caught, 129 were females and 97 were males, giving an overall sex ratio of 1 : 1.33 and the difference between the number of females and males was significant ($\chi^2 = 4.5310; P < 0.05$).

**Gonadosomatic and modified gonadosomatic indices.** Significant differences were observed in female
and male GSI and MGSI in different months ($P < 0.05$). There were no significant differences between GSI and MGSI ($P > 0.05$). The female indices increased during November to May, peaking at the mid of spring and then decreased until August, then showed a slow increase in October and finally decreased in November (Figs. 1, 2).

**Oocyte diameter and fecundity.** The oocyte diameter ranged from 0.02 to 1.4 mm with a mean of 0.5839 mm (SD ± 0.1578). They were highest in May and lowest in December. There was a peak in the number of yellowish-yolk oocytes (0.8–1.4 mm diameter) in May (Fig. 3).

The fish used to estimate fecundity were 3+, 4+, or 5+ years old. Individual values of the absolute fecundity varied in a wide range from 734 to 3562 eggs with an average of 2172.5

---

**Fig. 1.** Variation of mean (±SE) gonadosomatic index (GSI) of female (F) and male (M) for *Cobitis* sp. from the Babolrud River in different months

**Fig. 2.** Variation of mean (±SE) modified gonadosomatic index (MGSI) of female (F) and male (M) for *Cobitis* sp. from the Babolrud River in different months
(SD ± 719). The relative fecundity was 347 to 945 with a mean of 590.08 (SD ± 207) per gram body weight (Table 2).

It was observed that the absolute fecundity accompanied the growth of weight of the female loaches. The absolute fecundity was significantly related to fish female body weight and also gonad weight (Table 3).

**DISCUSSION**

**Age and size of fish.** Females achieve maturity later than the males; at the age of 2+, SL is about 56 mm and body weight about 2 g (Robotham 1981, Boroń and Pimpicka 2000). The loach is a short-lived species, most of the caught fish were 2+ and 3+ years old, some were 1+ and 4+ and only a few of them were 5+ years old (Robotham 1981), while in present study the oldest females (1.77%) were 5+ years old but most of them (40.71%) were in the third year of their lives.

**Reproduction.** This is the first study concerning reproduction process of *Cobitis* sp. in southern part of the Caspian Sea basin. Spawning of *C. taenia* takes place from May to July, usually in shallow littoral, among the submerged vegetation where the water temperature is at least 16–18°C (Boroń and Danilkiewicz 2000, Boroń and Pimpicka 2000). A similar time of spawning was observed for *C. bilineata* Canestrini, 1865 from northern Italy (Marconato and Rasotto 1989). A later spawning period (June–July) was observed for *C. taenia* from the United Kingdom (Robotham 1981). Ekmeği and Erk’akan (2003) showed that the *C. simplicispina* Hankó, 1925 from Turkey begins to spawn in April, when the water temperature is 15° and finishes in May. The spawning period in the Babolrud River lasted until the middle of July. As late as in mid-July, in some females ovaries filled with oocytes were observed ready to be laid. However, in August, the ovaries of all the

**Fig. 3.** The mean oocyte diameter [mm] in the gonads of *Cobitis* sp. from the Babolrud River.
loaches under study indicated end of the reproductive period. Then a secondary increasing in ovaries development was observed from August to October, when some of the fish was ready to spawn. In the Zegrzyński Reservoir, ovaries of the female loach were filled with mature eggs in August (Boroń and Pimpicka 2000).

The process of accumulating reserve substances in the ovaries of the females can be obtained partly by tracing the changes in the gonadosomatic index. In species which spawn in late spring and in summer such as loach, the index remains low in winter and then rises sharply just before the spawn (Wootton 1979, Marconato and Rasotto 1989, Rinchard and Kestemont 1996). A rapid increase in the weight of ovaries takes place when the temperature rises and increasing amounts of food are consumed (Wootton 1979).

Changes in the gonadosomatic index, calculated for the population in which females spawn in batches, must not be used as the only credible indicator of the number of batches laid. The highest GSI values from 18% for the fish from Lucień Lake (Kostrzewa et al. 2003) to 26% in the loach from Italy (Marconato and Rasotto 1989) were observed during reproduction period. Values of GSI, reported by different authors varied widely:

- from 2% to 20% for *C. elongatoides* Bacescu et Maier, 1969 from the Czech Republic (Halačka et al. 2000);
- from 12% to 26% for *C. taenia* from Italy (Marconato and Rasotto 1989);
- from 7% to 17% for *C. simplicispina* Hankó, 1925 from Turkey (Ekmekçi and Erk’akan 2003);
- from 5% to 18% for *Cobitis* sp. from Lucień Lake (Kostrzewa et al. 2003);
- from 5.2% to 12.2% for *C. elongatoides* from Hungary (Erős 2000).

On the other hand, the highest average value of GSI (calculated in late April, before spawning), of the population of *Cobitis* sp. from the Babolrud River, was about 9%, ranging from 4% to 26%.

**Fecundity.** It is difficult to determine the fecundity in females which spawn in batches as the fish under study. In order to estimate the absolute fecundity of the loach from the Babolrud River, all the oocytes of at least 0.2 mm in diameter were counted. A similar limiting value was adopted for *Cobitis* sp. from Lucień Lake (Kostrzewa et al. 2003). Some authors included larger oocytes, over 0.3 mm (Boroń and Pimpicka 2000) or over 1 mm (Boroń and Danilkiewicz 2000). In this study, the absolute fecundity of female loach from the Babolrud River was about 2172 eggs, ranging from 734 to 3562 eggs and the absolute fecundity of *Cobitis* sp. caught in Lucień Lake and Klawój Lake (Kostrzewa et al. 2003, Juchno and Boroń 2006) were comparable to the estimated value for the fish in the Babolrud River and equaled 2180 and 2078 eggs on average respectively. The absolute fecundity of the loach from Dgal Wielki Lake was low and ranged from 175 to 452 eggs, as only the oocytes larger than 1 mm were counted (Boroń and Danilkiewicz 2000). The number of oocytes obtained this way referred probably only to the first batch. Only the largest mature eggs were counted.

### Table 2

| Parameter | n | Fa range | Fa mean ± SD | Fr range | Fr mean ± SD |
|-----------|---|----------|--------------|----------|--------------|
| SL [mm]   |   | 50.1–60  | 11 734–1637  | 1467 ± 418 | 384–903  | 617 ± 225 |
|           |   | 60.1–70  | 14 918–2506  | 2049 ± 735 | 347–945  | 693 ± 241 |
|           |   | ≥70.1     | 5 1962–3562  | 2651 ± 642 | 415–877  | 532 ± 173 |

| Age       |   | 3+        | 18 859–2125  | 1529 ± 641 | 384–758  | 595 ± 172 |
|           |   | 4+        | 10 734–3194  | 2168 ± 803 | 347–945  | 612 ± 196 |
|           |   | 5+        | 2 2358–3562  | 2960 ± 851 | 387–584  | 485 ± 140 |

n = number of specimens; SD = standard deviation.

### Table 3

| Relation   | n | Linear regression | r² | F-value | P-value |
|------------|---|-------------------|----|---------|---------|
| Fa–TL      | 30 | y = 44.313x – 1022.2 | 0.5613 | 1.689 | 0.440 |
| Fa–Ws      | 30 | y = 483.79x + 389.57 | 0.6762 | 4.315 | 0.045 |
| Fa–Wg      | 30 | y = 1287.2x + 967.61 | 0.3034 | 24.385 | 0.022 |
| Fa–Age     | 30 | y = 655.84x – 437.33 | 0.2945 | 1.625 | 0.452 |
in order to estimate the fecundity of the loach in the northern Italy (Marconato and Rasotto 1989). In this case, the number of eggs equaled 1012. According to Lobón-Cerviá and Zabala (1984), the fecundity of the largest female \textit{C. paludicola} amounted to 1400 eggs, whereas according to Bohlen (1998) the fecundity of the females of this species was much higher and ranged from 2905 to 4258 eggs (3618 on average). Statistically significant relations were found between the absolute fecundity and body weight and gonad weight in \textit{Cobitis} sp. population from the Babolrud. The absolute fecundity of the fish from the Zegrzyński Reservoir ranged from 112 to 1520 eggs and was positively correlated with the body size, length, and the age of the females (Boroń and Pimpicka 2000) and the relative fecundity ranged from 28 to 204 eggs per 1 g of the body weight, 108 on average. The relative fecundity in a related species of \textit{C. elongatoides} ranged from 35 to 105 eggs (Erös 2000). The relative fecundity in the loach from the Babolrud River was higher and equalled 347 to 945 with a mean of 590 eggs per 1 g of a female body weight. According to present study, the relative fecundity in the loach from Kławój Lake amounted to 629 eggs (Juchno and Boroń 2006).

**ACKNOWLEDGEMENTS**

The authors are grateful to Cevher Ozeran, Ali Gholamifard and Fatih Mangit for their comments in this manuscript, Nihat Senol and Asta Aleksandrovicute for revision of the English and Hamid Ghasemnejad for his help in fish collections.
