Abstract

Mycobacterium tuberculosis (M. tuberculosis) is the causative agent of tuberculosis in human. One of the major M. tuberculosis virulence factors is early secretory antigenic target of 6-kDa (ESAT-6), and EccB5 protein encoded by eccB5 is one of its components. EccB5 protein is a transmembrane protein in ESX-5 system. The aim of this study is to explore the characteristics of wild-type EccB5 and its mutant form N426I. We expressed the EccB5 protein by cloning the mutant and wild-type eccB5 gene in Escherichia coli (E. coli). We compared the protein structure of wild type and mutant form of EccB5 and found changes in structure around Asn426 (loop structure) in wild type and around Ile426 (β-strand) in the mutant. The truncated recombinant protein of EccB5 was successfully cloned and expressed using plasmid pCold I in E. coli DH5α and E. coli strain Rosetta-gami B (DE3) and purified as a 38.6 kDa protein by using the affinity column. There was no detectable adenosine triphosphatase activity in truncated forms of EccB5 and its mutant. In conclusion, our study reveals successful cloning and protein expression of truncated form of eccB5 gene of M. tuberculosis. EccB5 protein in ESX-5 system may be an important membrane component involved in the transport machinery of type VII secretion system, which is essential for growth and virulence.

Keywords: M. tuberculosis; eccB5; ATPase; cloning; expression

Introduction

Tuberculosis (TB) is one of the major global public health problems. According to World Health Organization (WHO), Indonesia is regarded as a high TB burden country and holds the second highest position in the number of TB cases in the world. Incidence of TB cases in Indonesia is estimated to be about 1.02 million per year.1,2 WHO global TB report indicates that in 2017, Indonesia is still a high TB burden country, lies in third position for incident TB cases, after China.3

TB is an infectious disease in human caused by Mycobacterium tuberculosis and zoonotic TB is caused by M. bovis.1,4-6 M. tuberculosis is a pathogenic bacterial species of the mycobacteria genus and has many virulence factors and proteins secreted via type VII secretion systems (T7SSs) which are well documented.7-9 The T7SSs have five systems: ESX-1, ESX-2, ESX-3, ESX-4, and ESX-5. These secretion systems are important for virulence of mycobacteria, especially the ESX-5 system (Rv1782 - Rv1798) is only present in slow-growing mycobacteria.10,11 ESX-5 system has four core component (EccB5, EccC5, EccD5, and EccE5) the estimated size is about ~1500 kDa.12 Satta et al., reported that mutation in the eccB5 gene was observed

in the virulence gene from isolates found during isoniazid-resistant outbreak in London.\textsuperscript{13} The single-nucleotide polymorphism (SNP) was detected in eccB\textsubscript{5} gene located at position 2017898, numbers annotated from whole-genome database of M. tuberculosis, accession number: PRJEB13764, which resulted in the reduction of colony-forming unit (CFU) count.\textsuperscript{13} We have found in our previous study that SNP in the eccB\textsubscript{5} gene of isolates from Indonesia in the open reading frame region at 1277th nucleotide change in A/T.\textsuperscript{14}

The SNPs are the most common form of genetic variation, and the unique diversity is also observed in several genes. The SNPs could have the important effect on the phenotype of mycobacteria, which could influence the pathogenesis of M. tuberculosis infection, molecular epidemiology, demographic variations, phylogenetic markers, drug resistance, and gene functions.\textsuperscript{15}

In this study, we focused on the characteristics of EccB\textsubscript{5} of both wild type and mutant (1277 A/T) form of eccB\textsubscript{5} of M. tuberculosis by expressing the gene and purifying the recombinant protein. EccB\textsubscript{5} has high homology to EccB\textsubscript{1}, which has one or more motif for adenosine triphosphatase (ATPase) activity, so we performed the docking experiment with the Swiss model found in the database and measured the ATPase activity of purified truncated EccB\textsubscript{5} and its mutant.

**Materials and Methods**

**Plasmid and bacterial strain**

In this study, we used pCold I (Takara\textsuperscript{®}, Shiga, Japan) as an expression vector and Escherichia coli (E. coli) strain DH5\textsubscript{a} as a bacterial cloning host. We used E. coli strain Rosetta-gami B (DE3) as an expression host. E. coli strain DH5\textsubscript{a} and Rosetta-gami B (DE3) were cultured for preparing the competent cells according to the standard protocol.\textsuperscript{16} E. coli strain DH5\textsubscript{a} were cultured in Luria-Bertani (LB) media containing antibiotic ampicillin 100 µg/mL. The E. coli Rosetta-gami B (DE3) were grown in LB medium containing tetracycline (12.5 µg/mL), chloramphenicol (34 µg/mL), kanamycin (15 µg/mL), and ampicillin (100 µg/mL).

**Protein prediction and determination of transmembrane protein**

The protein structure prediction and homology was carried out using the Swiss Model.\textsuperscript{17,18} The protein model of EccB\textsubscript{5} was built using 3x3n for template.\textsuperscript{19} Transmembrane helices proteins region prediction was used to check and confirm the protein structural details.\textsuperscript{20,21}

**Construction of plasmid for expression of EccB\textsubscript{5}**

The eccB\textsubscript{5} gene was constructed using M. tuberculosis gene and EccB\textsubscript{5} protein was prepared in E. coli DH5\textsubscript{a} using the pCold I plasmid. Primer F EccB\textsubscript{5} 418 Eco (5’-ATA TGA ATT CGT GGG TAT CCC GGG TGC G-3’) and R- EccB\textsubscript{5} Xba (5’-TTA ATC TAG ATT TCG GTA CCA CCA ACT CTG-3’) used to amplify the truncated eccB\textsubscript{5} gene. The polymerase chain reaction (PCR) was performed by PrimeSTAR MAX DNA polymerase (Takara) using PCR thermal cycler according to the following set condition: predenaturation at 94°C for 2 min, denaturation at 98°C for 10 sec, annealing at 55°C for 5 sec, extension at 72°C for 5 sec, and total number of cycles are 20. Subsequently, PCR product was purified according to the protocol of DNA Purification Kit (Monarch\textsuperscript{®}, New England Biolabs Japan Inc., Tokyo, Japan). The PCR product was subsequently ligated to the expression vector and the pCold I W 418 and pCold I M 418 were obtained. Sequencing was performed for confirmation of the DNA target sequences.

**Expression of recombinant protein of EccB\textsubscript{5} in E. coli strain Rosetta-gami B (DE3)**

The cloned plasmids were transformed into E. coli Rosetta-gami B (DE3). The single colony was picked and inoculated in 1.5 mL of LB broth containing appropriate antibiotics and incubated at 37°C for 24 h with shaking. Five hundred microliter of the bacterial cultures were transferred into 50 mL of LB broth containing adequate antibiotics and incubated at 37°C. After reaching the OD\textsubscript{600} = 0.6, cells were induced by 1.0 mM isopropyl β-D-1-thiogalactopyranoside and then cultured at 15°C for 16 h for expression.

**Extraction and purification of recombinant protein**

E. coli cells were harvested, and the wet weight was determined. Cells were extracted using Bug Buster\textsuperscript{®} (Merck, Tokyo, Japan) according to the manufacturer’s protocol. The crude protein was purified using Talon\textsuperscript{®} metal resin (Clontec Laboratories Inc., CA). The extracted protein was dialyzed against 10 mM Tris HCl, pH 7.5.

**Sodium dodecyl sulfate-polycrylamide gel electrophoresis and western blot**

In brief, 4 µL of extracted protein samples were loaded on the wells of 12.5% sodium dodecyl sulfate-polycrylamide gel electrophoresis (SDS-PAGE). The separated protein on SDS-PAGE was stained using Coomassie brilliant blue.
Anti-His antibodies (primary antibody, Novagen®/C210; EMD Chemical, Inc., Germany) and horse radish peroxidase-linked anti-mouse IgG (secondary antibody; Cell Signaling Technology, Inc.) were used for detection in a western blot (WB) analysis.

**ATPase activity**

The ATPase activity was measured using the ATPase assay kit (Sigma-Aldrich), according to the protocol of Sigma-Aldrich. In brief, 10 μL of the concentrated samples were dispensed into microplate. Ten microliter
of 4 mM ATP was added in 20 μL assay buffer and incubated at room temperature for 30 min. Two hundred microliter of the reagent was added to each well and was incubated for 30 min at room temperature. Readings at 600–650 nm was taken with enzyme-linked immunosorbent assay plate reader (Vmax).

**Molecular modeling of EccB5**

Homology modeling was performed using the SWISS model. Modeling of the EccB5 hexamer was performed using SymmDock. The model with the highest geometric shape complementarity scores were chosen as the model of EccB5. Molecular operating environment (MOE) was used as the platform for the docking simulation with ATP.

**Results**

**Prediction of protein structure of EccB5**

The prediction protein structure of EccB5 full form were explored by using PyMol software, the Molecular Graphic System, by Schrödinger, to locate mutation A1277T using 3x3n as template X-ray, 2.0 Å (Fig. 1). The secondary structure of wild-type EccB5 shows amino acid residues of Asn426 as a cartoon model in magenta (Fig. 1A). While amino acid residues of mutant EccB5 Ile426 in cartoon model (β-strand structure) are as shown in magenta (Fig. 1B), the superimposed structure of EccB5 protein wild type and mutant consists of α-helical structure (α1-α 10) and β-strand structure (β1-β17) are as shown in Figure 1C. Analysis of root mean square deviation between mutant and wild type is 0.015 Å, these indicate that both proteins have similar structure.

In this study, we tried to express recombinant EccB5 protein in *E. coli* strain Rosetta-gami B (DE3) in full form, but the results showed that the expression was negligible (data not shown). So, to increase the amount of protein, the nucleotide sequences at the N-terminal transmembrane region were deleted from the full form. Analyses showed that the transmembrane region of eccB5 gene was at position 54–76 of amino acid residues.

In this study, the nucleotide sequences (1–417) were deleted and primer was designed to include the gene starting from 418 of nucleotide sequences to the stop codon. The molecular weight of truncated recombinant protein of EccB5 (rEccB5) was estimated to be ~38.6 kDa.

**Expression of EccB5 in *E. coli* strain Rosetta-gami B (DE3)**

The expression of rEccB5 in *E. coli* strain Rosetta-gami B (DE3) is as shown in Figure 2A. The molecular weight of rEccB5 is 38.6 kDa and the bands are shown in black arrows. The target protein was extracted by using Bug Buster as shown in CBB staining (lane 1, 2, 3). Extracted protein was purified by using Talon metal resin. The SDS-PAGE of the purified protein after dialysis in 10 mM Tris HCl pH75 is shown as a distinct band in
CBB stain (lane 5, 6, black arrows). It is clear that the protein of interest was purified up to a certain level of purity. WB analysis of purified rEccB5 using anti-His-Tag antibodies is shown in Figure 2B. It is clear that rEccB5 of wild type and mutant was expressed in *E. coli* and detected by the antibody.

**ATPase activity**

The purified protein was collected and ATPase activity was measured. There was no significant ATPase activity in both mutant and wild-type rEccB5 expressed in *E. coli* Rosetta-gami B (DE3) (data not shown). Predictable ATPase motif PX2NLXSARL is present at the N-terminal region of EccB1, so it is reasonable that the truncated EccB5 has no ATPase activity. The N-terminal of EccB5 may be playing a major role in ATPase activity, but the study needs further evaluation.

**Modeling of the EccB5 protein**

We analyzed the full length of EccB5 using SWISS model of EccB5 and the structure of the hexamer oligomer was predicted using SymmDock web server. Most ATPase functions as hexamers and so we hypothesized that the EccB5 forms a hexamer like that of EccB1. Figure 3A shows the predicted EccB5 hexamer as seen from the top, and the six monomers of EccB5 are indicated in different colors. In the middle of the hexameric oligomers is the small pore like gap, similar to the one seen in EccB1 predictable due to high homology to each other. The predicted structure of the EccB5 hexamer is as observed from the sides of the hexamer (Fig. 3B). This model was used to dock the ATP molecule into EccB5 hexamer. MOE was used as the platform for the simulation. The results of the simulation are as shown in Figure 3C. The ATP molecule is shown as a stick model and is located at the interface of EccB5. The ribbon model shows the location of ATP in EccB5 hexamer. The amino acids indicated are involved in the interaction with ATP. It is likely that Arg455 and Leu462 largely interact with ATP. Enlargement of the ribbon model at ATP interaction shows that Asn426 is adjacent to ATP-binding site (Fig. 3E). From the structural simulation, it seems likely that Asn426 is not directly involved in the interaction of EccB5 with ATP. The distance between the ATP and Asn426 is within 10 Å. In this simulation, neither water molecules nor metallic ions are included, so we cannot rule out the possibility that Asn426 is not directly involved in the interaction with ATP. Further
experimentation with the crystallization of EccB5 with ATP may reveal the exact involvement of Asn426 in ATP binding.

Discussion
TB is an infectious disease caused by \textit{M. tuberculosis}. \textit{M. tuberculosis} is member of mycobacteria tuberculosis complex and is included in the slow growing mycobacteria group. Slow-growing mycobacteria have one of the unique secretion systems, namely the ESX-5 system.\textsuperscript{7,8,23} ESX-5 system consists of 16 coding genes, one of them is eccB5 gene.\textsuperscript{9,24}

In previous study, the SNP in locus 1277 T/A of eccB5 nucleotide sequences, which is known as nonsynonymous SNP (nsSNP), was found, and single amino acid change at position 426 from Aspartic acid residue to Isoleucine was observed.\textsuperscript{14} However, the function of the protein is not clear, so we expressed the recombinant eccB5 gene and analyzed the wild-type and the mutated N426I EccB5 protein.

To know the structural differences of the EccB5 protein, prediction of the 3D protein models was done based on the database obtained from Swiss model and compared the structure of mutant and wild type using 3x3n template.\textsuperscript{19} The mutated region showed \(\beta\)-strand structure, while the wild type showed the loop structure prediction. These changes may be due to the changes in amino acid residues Asn426, which has hydrophilic side chain to Ile426, which has hydrophobic side groups. The structure of the hexamer

\textbf{FIG. 3.} Putative models of EccB5 hexamer and ATP pocket. (A) Top view of the proposed sixfold rotational symmetric oligomer of EccB5. (B) Side view of the EccB5 hexamer. (C) The putative structure of ATP-binding site. ATP molecule is shown as a stick model. (D) The amino acid which were predicted to be localized within 4.5 \(\text{Å}\) from ATP molecule using molecular operating environment ligand interactions application. Green circles indicate the interaction between amino acid side chains with ATP and the blue circles show the interaction between amino acid backbone with ATP. (E) Enlargement of the binding pocket area of ATP. Asn426 region is shown as a stick model. ATP, adenosine triphosphate.
oligomer was predicted using SymmDock web server as seen in Figure 3. This model was used to dock the ATP molecule into EccB5 hexamer. MOE was used as the platform for the simulation. The results of the simulation are as shown in Figure 3C. The ATP molecule is located at the interface of adjacent EccB5. Amino acids Arg455 and Leu462 have stronger interaction with ATP. Enlargement of the ribbon model at ATP interaction, shows Asn426 adjacent to ATP-binding site. The distance between the ATP and Asn426 is within 10 Å. In this simulation, neither water molecules nor metallic ions are included, so we cannot rule out the possibility that Asn426 is not directly involved in the interaction with ATP. Further experimentation with the crystallization of EccB5 with ATP may reveal the exact involvement of Asn426 in ATP binding.

Although we tried to express the full forms of \( eccB_{5} \) gene, the protein expression was negligible. The result is similar to that obtained by Beckham et al.\(^{25} \) EccB5 expression is low probably due to the low stability of a single protein in the ESX-5 complex system. To overexpress the protein, we deleted the N-terminal trans-membrane helices protein region of 417 nucleotide sequences. There are reports that the presence of the transmembrane protein results in extremely low level of the expressed protein.\(^{26} \) The truncated recombinant protein of wild-type and mutant EccB5 was successfully expressed in \( E. \ coli \) Rosetta-gami B (DE3). In addition, the growth of recombinant bacteria between \( E. \ coli \) expressing mutant and wild type was no different. The growth of \( E. \ coli \) expressing wild-type EccB5 was higher than those expressing the mutant EccB5. Interestingly, the yield of the mutated EccB5 was lower compared to the wild-type EccB5 as observed from the bands of the CBB stain. Purification does not alter the amount of protein obtained. Amino acid residues of Asn are often involved in active binding sites of the protein, probably due to their polar nature. On the contrary, amino acid residue of Ile is nonreactive and infrequently involved in direct protein function, but sometimes involved in substrate recognition due to the hydrophobic nature of the side chain.\(^{27} \) SNP of \( eccB_{5} \) gene was also found in different locations of T/T, and reduced CFU count was observed in \( M. \ tuberculous. \)\(^{13} \) The \( eccB_{5} \) gene on the ESX-5 system in \( M. \ tuberculous \) has important functions, such as viability, nutritional uptake, and cell wall integrity.\(^{28} \) Di Luca et al., also described that deletion of \( eccB_{5}-eccC_{5} \) gene affected bacterial growth of \( Mycobacterium marinum. \)\(^{28} \)

In this study, we measured the ATPase activity, but there was no significant ATPase activity in both wild-type and mutant EccB5. In a previous study, it was shown that EccB1 is a periplasmic ATPase, and EccB5 is highly homologous to EccB1 in ESX system.\(^{19} \) Our EccB5 is expressed as a truncated form, so it may be possible that the ATPase function is lost when the N-terminal motif PX2NLXSARL is deleted. According to Zhang et al., ATPase motif PX2NLXSARL at N-terminal position has direct involvement in ATPase activity.\(^{19} \)

ATPase is one of the important enzymes in bacteria, such as for driving substrates across the inner membrane using ATP dephosphorylation activity.\(^{19,29} \) EccB5 hexamer may function as a part of a transport channel of the huge type VII secretion membrane system. Houben et al., reported that EccB5 located at the cell envelope of \( M. \ marinum \) forms a large membrane complex along with EccC, EccD, and EccE, and so it is likely that EccB5 of \( M. \ tuberculous \) may be involved in the formation of channel spanning the plasma and mycobacterial membrane.\(^{12} \) Also as such, it may have an important role as virulence factor in \( M. \ tuberculous \) and may be a possible target for drug design.
