Abstract

We prove some variants of the exponential formula and apply them to the multivariate Tutte polynomials (also known as Potts-model partition functions) of graphs. We also prove some further identities for the multivariate Tutte polynomial, which generalize an identity for counting connected graphs found by Riordan, Nijenhuis, Wilf and Kreweras and in more general form by Leroux and Gessel, and an identity for the inversion enumerator of trees found by Mallows, Riordan and Kreweras. Finally, we prove a generalization of Möbius inversion on the partition lattice.

Key Words: Exponential formula, generating function, sequence of binomial type, convolution family, graph, connected component, Tutte polynomial, Potts model, complete graph, inversion enumerator for trees, Abel’s binomial identity, Chu–Vandermonde convolution, Rothe’s identity, Möbius inversion, partition lattice.

1 Introduction

Let \( \{c_n\}_{n=1}^{\infty} \) be a sequence of coefficients, and let
\[
C(x) = \sum_{n=1}^{\infty} \frac{c_n x^n}{n!}
\]
be the corresponding exponential generating function, considered as a formal power series in the indeterminate \( x \). Now let \( q \) be another (commuting) indeterminate\(^1\), and define
\[
A_q(x) = \exp[qC(x)] = \sum_{n=0}^{\infty} \frac{a_n(q) x^n}{n!},
\]
so that \( A_q(x) = A(x)^q \) [we write \( A(x) = A_1(x) \)]. It is easy to see that:

(a) Each coefficient \( a_n(q) \) is a polynomial in \( q \), of degree at most \( n \); indeed we have the explicit formula
\[
a_n(q) = \sum_{\ell=0}^{n} \frac{q^\ell}{\ell!} \sum_{\substack{n_1, \ldots, n_\ell \geq 1 \ \text{\ \ \ \ \ \ } \sum n_j = n}} \prod_{j=1}^{\ell} c_{n_j}.
\]

(b) \( a_0(q) = 1 \).

(c) For \( n \neq 0 \), the polynomial \( a_n(q) \) has zero constant term, so that we can write \( a_n(q) = q \hat{a}_n(q) \) where \( \hat{a}_n(q) \) is a polynomial of degree at most \( n - 1 \); moreover we have \( \hat{a}_n(0) = c_n \).

For some purposes it is convenient to introduce the modified generating function
\[
\hat{A}_q(x) = \frac{A_q(x) - 1}{q} = \frac{\exp[qC(x)] - 1}{q} = \sum_{n=1}^{\infty} \frac{\hat{a}_n(q) x^n}{n!}.
\]
The coefficients \( \{a_n(q)\}_{n=0}^{\infty} \) furthermore satisfy the following identities [23]:\(^3\)
\[
\sum_{k=0}^{n} \binom{n}{k} a_k(q_1) a_{n-k}(q_2) = a_n(q_1 + q_2) \quad \text{for } n \geq 1
\]
\[
\sum_{k=1}^{n} \binom{n}{k} \hat{a}_k(q_1) a_{n-k}(q_2) = n \hat{a}_n(q_1 + q_2) \quad \text{for } n \geq 1
\]

\(^1\)Let us stress that this \( q \) has nothing to do with the \( q \) of \( q \)-series; rather, it is connected with the \( q \) of the \( q \)-state Potts model [44, 68, 69] and of the multivariate Tutte polynomial [57].

\(^2\)This formula holds also for \( n = 0 \) because the integer 0 has exactly one ordered partition \((n_1, \ldots, n_\ell)\) into zero or more strictly positive parts: namely, we have \( \ell = 0 \) parts, and the multinomial coefficient and the empty product both equal 1, correctly giving \( a_0(q) = 1 \).

\(^3\)See Gould [23] for fascinating comments on the history of identities equivalent to (1.6) [or to (1.10) below], which apparently go back to Euler (1748), Rothe (1793), Hindenburg (1796), von Ettingshausen (1826) and Hanstead (1881), among others.
Indeed, (1.5) follows from writing the trivial identity
\[ A_{q_1}(x)A_{q_2}(x) = A_{q_1+q_2}(x) \] (1.7)
and extracting the coefficient of \(x^n\), while (1.6) follows analogously from
\[ A_{q_2}(x) \left[ \frac{x}{dx} \frac{A_{q_1}(x) - 1}{q_1} \right] = \frac{x}{dx} \frac{A_{q_1+q_2}(x) - 1}{q_1 + q_2} \] (1.8)
[23, eq. (4.3)], which is an easy consequence of (1.2). Specializing (1.6) to \(q_1 = 0\), or alternatively applying \(\frac{x}{dx}\) directly to (1.2), we obtain the well-known recursion relation [67, Theorem 3.10.1]
\[ a_n(q) = q \sum_{k=1}^{n} \binom{n-1}{k-1} c_k a_{n-k}(q) \quad \text{for } n \geq 1, \] (1.9)
which allows the \(\{a_n(q)\}\) to be calculated given the \(\{c_n\}\), or vice versa. More generally, we can form the linear combination \(n \times (1.5) - (q_1 + q_2) \times (1.6)\) to obtain the recursion relation
\[ a_n(q_2) = \sum_{k=1}^{n} \left[ \binom{n-1}{k-1} (q_1 + q_2) - \binom{n}{k} q_1 \right] \tilde{a}_k(q_1) a_{n-k}(q_2) \] (1.10a)
\[ = \sum_{k=1}^{n} \left[ \binom{n-1}{k-1} q_2 - \binom{n-1}{k} q_1 \right] \tilde{a}_k(q_1) a_{n-k}(q_2) \] (1.10b)
for \(n \geq 1\), which allows the \(\{a_n(q_2)\}\) to be calculated given the \(\{\tilde{a}_n(q_1)\}\) for any fixed \(q_1\), and which reduces to (1.9) when \(q_1 = 0\). We do not know whether there exist useful analogues of (1.5)/(1.6) with higher powers of \(k\) on the left-hand side.

Combinatorially, all these identities are versions of the exponential formula [5, 13, 14, 60, 64, 67], which relates the weights \(c_n\) of “connected” objects to the weights \(a_n(q)\) of “all” objects, when the weight of an object is defined to be the product of the weights of its “connected components” times a factor \(q\) for each connected component. This idea can be formalized in the following combinatorial model: Let \(\Pi_n\) be the set of partitions of \([n] \equiv \{1, \ldots, n\}\) into (zero or more) nonempty blocks; give

\[ a_n(q_2) = \sum_{k=1}^{n} \left[ \binom{n-1}{k-1} (q_1 + q_2) - \binom{n}{k} q_1 \right] \tilde{a}_k(q_1) a_{n-k}(q_2) \] (1.10a)
\[ = \sum_{k=1}^{n} \left[ \binom{n-1}{k-1} q_2 - \binom{n-1}{k} q_1 \right] \tilde{a}_k(q_1) a_{n-k}(q_2) \] (1.10b)

for \(n \geq 1\), which allows the \(\{a_n(q_2)\}\) to be calculated given the \(\{\tilde{a}_n(q_1)\}\) for any fixed \(q_1\), and which reduces to (1.9) when \(q_1 = 0\). We do not know whether there exist useful analogues of (1.5)/(1.6) with higher powers of \(k\) on the left-hand side.

Combinatorially, all these identities are versions of the exponential formula [5, 13, 14, 60, 64, 67], which relates the weights \(c_n\) of “connected” objects to the weights \(a_n(q)\) of “all” objects, when the weight of an object is defined to be the product of the weights of its “connected components” times a factor \(q\) for each connected component. This idea can be formalized in the following combinatorial model: Let \(\Pi_n\) be the set of partitions of \([n] \equiv \{1, \ldots, n\}\) into (zero or more) nonempty blocks; give

\[ a_n(q_2) = \sum_{k=1}^{n} \left[ \binom{n-1}{k-1} (q_1 + q_2) - \binom{n}{k} q_1 \right] \tilde{a}_k(q_1) a_{n-k}(q_2) \] (1.10a)
\[ = \sum_{k=1}^{n} \left[ \binom{n-1}{k-1} q_2 - \binom{n-1}{k} q_1 \right] \tilde{a}_k(q_1) a_{n-k}(q_2) \] (1.10b)

4See [23, eq. (1.3)] or [59, Exercise 1.39, pp. 50 and 62] for the case \(q_1 = 1\), which is of course trivially equivalent to the general case of \(q_1 \neq 0\).

4In the theory of combinatorial species [5], the exponential formula is merely a special case of the more general concept of composition (or substitution) of species \(F \circ G\) [5, section 1.4.1], which is defined so that the exponential generating function of \(F \circ G\) is the composition of the exponential generating functions of \(F\) and \(G\). When \(F\) is taken to be the species \(E\) of sets (ensembles in French) and \(H\) is some species for which there exists a reasonable notion of connectedness, then, letting \(H^c\) be the subspecies of connected \(H\)-structures, we have the isomorphism of species \(H = E \circ H^c\); since the exponential generating function of \(E\) is \(\exp\), this immediately implies the exponential formula \(H(x) = \exp(H^c(x))\). This result also generalizes to weighted and multi-sort species. See [34] for results closely related to those of the present paper, formulated in the language of species.
a partition \( \pi = \{ \pi_1, \ldots, \pi_\ell \} \) a weight \( w(\pi) = q^\ell \prod_{i=1}^\ell c_{|\pi_i|} \) where \( \{c_k\}_{k=1}^\infty \) are arbitrary coefficients; and let \( a_n(q) = \sum_{\pi \in \Pi_n} w(\pi) \). Then (1.3) is immediate: the multinomial coefficient counts the ordered partitions of \([n]\) into blocks of sizes \( n_1, \ldots, n_\ell \), and the \( 1/\ell! \) converts this to unordered partitions. As for (1.5)/(1.6), we first observe that \( a_n(q_1 + q_2) \) can be computed by allowing each block to be colored either “1” (with weight \( q_1 \)) or “2” (with weight \( q_2 \)). Identity (1.5) follows by defining \( S \subseteq [n] \) to be the set of elements colored “1”, and setting \( k = |S| \). Analogously, \( \hat{a}_n(q_1 + q_2) \) can be computed by coloring and weighting blocks as before, except that the block containing one specified element \( i \in [n] \) (say, \( i = 1 \)) must be colored “1” and it receives weight 1 instead of weight \( q_1 \). Defining again \( S \subseteq [n] \) to be the set of elements colored “1”, and setting \( k = |S| \), we obtain (1.6) in the form:

\[
\hat{a}_n(q_1 + q_2) = \sum_{k=1}^n \binom{n-1}{k-1} \hat{a}_k(q_1) a_{n-k}(q_2) \quad \text{for } n \geq 1 .
\] (1.11)

Sequences of polynomials \( \{a_n(q)\} \) satisfying (1.2) [or equivalently satisfying (1.5) and not identically zero] have been termed sequences of binomial type by Rota and collaborators \([12, 16, 39, 48, 49, 51]\) and studied by means of the umbral calculus \([18, 49, 52]\). The corresponding sequences \( \{a_n(q)/n!\} \) have been termed sequences of binomial type by Labelle \([32]\) and convolution families by Knuth \([30]\) and Zeng \([70]\); these authors used elementary formal-power-series methods closely resembling those used here. A purely combinatorial approach to sequences of binomial type, employing the theory of species, has been developed by Labelle \([33]\) (see also \([5, \text{section 3.1}]\)).

Further identities, generalizing (1.5)/(1.6), can be obtained by a powerful transformation suggested by Knuth \([30]\). Start with any formal power series \( A(x) \) with constant term 1; set \( A_q(x) = A(x)^q \) and define polynomials \( \{a_n(q)\} \) by (1.2). Now let \( t \) be a parameter, and define a formal power series \( A(x; t) \) by the implicit equation:

\[
A(x; t) = A(xA(x; t)^q) .
\] (1.12)

Since \( A(x; 0) = A(x) \), we can view the family \( \{A(x; t)\}_{t \in \mathbb{R}} \) as a special class of “perturbations” of \( A(x) \). Now define polynomials \( \{a_n(q; t)\} \) by the obvious formula:

\[
A(x; t)^q = \sum_{n=0}^\infty a_n(q; t) \frac{x^n}{n!} .
\] (1.13)

---

6The coefficients \( c_k \) may in turn be generating functions for some additional structure on the set \([k]\) — for instance, a graph, a digraph, a hypergraph, etc. — under the condition that this structure is “connected”.

7See also \([45, \text{Theorem 2.9}]\); and see \([5, \text{p. 188, Exercise 3.1.20(a)}]\) for the special case \( q_1 = 1 \).

8It is not hard to see by induction that if \( \{a_n(q)\} \) satisfies (1.5) [or even the special case of (1.5) with \( q_1 = q_2 \)] and is not identically zero, then \( \text{deg} \ a_n \leq n \) with \( a_0 = 1 \) and \( a_n(0) = 0 \) for \( n \geq 1 \); moreover, with a little extra work it can be shown that \( A_q(x) \) is necessarily of the form (1.2): see \([16, \text{Theorem 4.1}]\) [30, 70] [60, Exercise 5.37, pp. 87–88 and 131–132].

Let us also remark that Rota et al. \([39, 51]\) and many subsequent authors \([12, 16, 48, 49]\), in defining “sequence of binomial type”, impose the additional condition that \( \text{deg} \ a_n = n \) exactly (i.e. \( c_1 \neq 0 \)); but since this condition is irrelevant for our purposes, we prefer not to impose it.
For each $t$, these polynomials form a family of the type (1.2) and thus satisfy the identities (1.5)/(1.6). On the other hand, a straightforward calculation using the Lagrange inversion formula [60] yields the remarkable relation

$$a_n(q; t) = \frac{q}{q + nt} a_n(q + nt) = q \tilde{a}_n(q + nt),$$  \hspace{1cm} (1.14)

or even more simply

$$\tilde{a}_n(q; t) = \tilde{a}_n(q + nt).$$  \hspace{1cm} (1.15)

[In particular, $a_n(q; t)$ and $\tilde{a}_n(q; t)$ are polynomials jointly in $q$ and $t$, so we can treat $t$ as an indeterminate if we wish.] It follows that, for any family $\{a_n(q)\}$ of type (1.2), we have the following identities generalizing (1.5)/(1.6):\(^9\)

$$\sum_{k=0}^{n} \binom{n}{k} q_1 \tilde{a}_k(q_1 + kt) q_2 \tilde{a}_{n-k}(q_2 + (n - k)t) = (q_1 + q_2) \tilde{a}_n(q_1 + q_2 + nt) \hspace{1cm} (1.16)$$

$$\sum_{k=1}^{n} \binom{n}{k} k \tilde{a}_k(q_1 + kt) q_2 \tilde{a}_{n-k}(q_2 + (n - k)t) = n \tilde{a}_n(q_1 + q_2 + nt) \hspace{1cm} \text{for } n \geq 1 \hspace{1cm} (1.17)$$

where we understand that $q \tilde{a}_0(q) = 1$. Multiplying (1.17) by $t$ and summing it with (1.16), we obtain the alternate form

$$\sum_{k=0}^{n} \binom{n}{k} a_k(q_1 + kt) q_2 \tilde{a}_{n-k}(q_2 + (n - k)t) = a_n(q_1 + q_2 + nt). \hspace{1cm} (1.18)$$

If in (1.18) we interchange $k \leftrightarrow n - k$ and $q_1 \leftrightarrow q_2$ and then replace $q_2$ by $q_2 - nt$, we obtain the slightly simpler form

$$\sum_{k=0}^{n} \binom{n}{k} q_1 \tilde{a}_k(q_1 + kt) a_{n-k}(q_2 - kt) = a_n(q_1 + q_2). \hspace{1cm} (1.19)$$

A combinatorial proof and interpretation of (1.16)/(1.18) in terms of the theory of species has been given by Labelle [33].\(^1\) We call (1.16)–(1.19) Abel-type extensions of (1.5)/(1.6) because in the simplest case $A(x) = e^x$, $a_n(q) = q^n$ they reduce to Abel’s celebrated extensions of the binomial theorem (also discovered simultaneously by Cauchy) [28, 46, 61].

These Abel-type formulae can alternatively be derived as immediate consequences of the Pfaff–Cauchy derivative identities (generalizations of Leibniz’s rule for the $n$th

---

\(^9\)See [60, Exercises 5.37(e) and 5.58, pp. 87–88, 99, 131–133 and 148], where the argument is attributed to Eric Rains and Ira Gessel. Please note also that if we write $f(x) = x/A(x)^t$ and $g(x) = xA(x; t)^t$, then $f$ and $g$ are compositional inverses (as observed in [30, 32] for $t = 1$).

\(^1\)Already Rota et al. [51, p. 711, Proposition 4] and Reiner [45, Theorem 2.10] noticed that, for any $t$, the family $\{a_n(q; t)\}$ defined by (1.14) is of type (1.2). But they do not seem to have noticed the relation (1.12), which to our knowledge goes back to Knuth [30].

\(^1\)See also [5, p. 189, Exercise 3.1.22] for a brief summary.

Table 1: Some classical identities that are special cases of (1.5)/(1.6) and (1.16)–(1.19). See [21–24, 28, 46, 61] for more information concerning Abel–Cauchy and Chu–Vandermonde–Rothe identities. The identity (1.5) is well known for the Bell [11, p. 136, eq. 3n] and Laguerre [2, p. 192, eq. 41] [36, p. 96, Problem 20] polynomials. We do not know any references for (1.6) or (1.16)–(1.19) in these cases.

derivative of the product of two functions) recently presented by Johnson [28]. Indeed, setting $v = A(x)^n$, $w = A(x)^\alpha$, $\phi = A(x)^\ell$ in [28, eq. (1.1)] yields (1.19), while making the same substitution in [28, eq. (1.4)] yields (1.16).

Some classical examples of families \{\(a_n(q)\)\} and the corresponding identities (1.5)/(1.6) and (1.16)–(1.19) are listed in Table 1.

In this note we begin by proving some easy generalizations of the foregoing formulae to the case in which the integer index $n$ is replaced by a multi-index $\mathbf{n}$ over a finite ground set $V$. We then show some applications of the latter formulae to the multivariate Tutte polynomial [57] of a graph $G = (V, E)$. Finally, we derive some further identities for the multivariate Tutte polynomial, which generalize an identity for counting connected graphs found by Riordan, Nijenhuis, Wilf and Kreweras [31,40,47] and in more general form by Leroux [37] and Gessel [17] and an identity for the inversion enumerator of trees found by Mallows, Riordan and Kreweras [31, 38]. In the appendix we prove an apparently new generalization of Möbius inversion on the partition lattice.

We stress that many (though not all) of the formulae derived in this paper are already known. But we think that our approach provides a unified perspective that may be of interest.

6
2 Variants of the exponential formula

Let $V$ be a finite ground set; we shall use multi-indices $\mathbf{n} = (n_i)_{i \in V} \in \mathbb{N}^V$ and commuting indeterminates $\mathbf{x} = (x_i)_{i \in V}$. We write $|\mathbf{n}| = \sum_{i \in V} n_i$ and $\mathbf{x}^\mathbf{n} = \prod_{i \in V} x_i^{n_i}$. We use the notation $\mathbf{n}! = \prod_{i \in V} n_i!$ and analogously for binomial and multinomial coefficients. Finally, we denote by $\mathbf{0}$ (resp. $\mathbf{1}$) the multi-index with all entries $0$ (resp. $1$); and for any subset $W \subseteq V$, we denote by $\mathbf{1}_W$ the multi-index taking the value $1$ on $W$ and $0$ on $V \setminus W$.

Let $R$ be a commutative ring containing the rationals as a subring; we shall use polynomials and formal power series whose coefficients lie in $R$. (In applications, $R$ will usually be either the rationals, reals or complex numbers, or a ring of polynomials or formal power series over one of these fields.) One possible approach is to treat the coefficients $c_\mathbf{n} = (c_\mathbf{n})_{\mathbf{n} \in \mathbb{N}^V \setminus \{\mathbf{0}\}}$ as indeterminates, and to take $R$ to be the polynomial ring $\mathbb{Q}[c]$; this approach has the advantage of exhibiting the polynomial dependence on the coefficients $c_\mathbf{n}$. But we need not commit ourselves to any specific choice of the ring $R$; all of our identities will be valid in complete generality.

So let $(c_\mathbf{n})_{\mathbf{n} \in \mathbb{N}^V}$ be a sequence of coefficients in the ring $R$, with $c_\mathbf{0} = 0$; and let

$$C(\mathbf{x}) = \sum_{\mathbf{n}} c_\mathbf{n} \frac{\mathbf{x}^\mathbf{n}}{\mathbf{n}!}$$

be the corresponding exponential generating function, considered as a formal power series in the indeterminates $\mathbf{x}$. Now let $q$ be another (commuting) indeterminate, and define

$$A_q(\mathbf{x}) = \exp[qC(\mathbf{x})] = \sum_{\mathbf{n}} a_\mathbf{n}(q) \frac{\mathbf{x}^\mathbf{n}}{\mathbf{n}!}.$$

Using the Taylor series for $\exp$, we deduce immediately that

(a) Each coefficient $a_\mathbf{n}(q)$ is a polynomial in $q$, of degree at most $|\mathbf{n}|$; indeed we have the explicit formula\(^{12}\)

$$a_\mathbf{n}(q) = \sum_{\ell=0}^{|\mathbf{n}|} \frac{q^{\ell}}{\ell!} \sum_{\mathbf{n}_1, \ldots, \mathbf{n}_\ell \neq \mathbf{0}} \left( \frac{\mathbf{n}}{\mathbf{n}_1, \ldots, \mathbf{n}_\ell} \right) \prod_{j=1}^{\ell} c_{\mathbf{n}_j}. \quad (2.3)$$

(b) $a_\mathbf{0}(q) = 1$.

(c) For $\mathbf{n} \neq \mathbf{0}$, the polynomial $a_\mathbf{n}(q)$ has zero constant term, so that we can write $a_\mathbf{n}(q) = q \tilde{a}_\mathbf{n}(q)$ where $\tilde{a}_\mathbf{n}(q)$ is a polynomial of degree at most $|\mathbf{n}| - 1$; moreover we have $\tilde{a}_\mathbf{n}(0) = c_\mathbf{n}$.

\(^{12}\)This formula holds also for $\mathbf{n} = \mathbf{0}$ because the multi-index $\mathbf{0}$ has exactly one ordered partition $(\mathbf{n}_1, \ldots, \mathbf{n}_\ell)$ into zero or more nonvanishing parts: namely, we have $\ell = 0$ parts, and the multinomial coefficient and the empty product both equal 1, correctly giving $a_\mathbf{0}(q) = 1$. This same observation applies to all subsequent formulae of a similar type, such as (2.7) ff.
Conversely, it is not hard to see that if \((c_n)_{n \in \mathbb{N} \setminus \{0\}}\) is any sequence and we define \((a_n(q))_{n \in \mathbb{N}}\) by (2.3), then the latter family satisfies (2.2).

Using \(q C(x) = \log A_q(x)\) together with the Taylor series for \(\log(1 + z)\), we obtain the inverse formula

\[
qc_n = \sum_{\ell=1}^{n} \frac{(-q)^{\ell-1}}{\ell} \sum_{\frac{n_1, \ldots, n_\ell}{\sum n_j = n}} \binom{n}{n_1, \ldots, n_\ell} \prod_{j=1}^{\ell} a_{n_j}(q) \quad (2.4)
\]

or equivalently

\[
c_n = \sum_{\ell=1}^{n} \frac{(-q)^{\ell-1}}{\ell} \sum_{\frac{n_1, \ldots, n_\ell}{\sum n_j = n}} \binom{n}{n_1, \ldots, n_\ell} \prod_{j=1}^{\ell} \hat{a}_{n_j}(q) . \quad (2.5)
\]

It is a nontrivial fact that the right-hand side of (2.5) is independent of \(q\).

Now let \(r\) be another indeterminate, and let us use the identity \(A_{rq}(x) = A_q(x)^r\) together with the Taylor series

\[
(1 + z)^r \equiv \exp[r \log(1 + z)] = \sum_{\ell=0}^{\infty} \frac{r^\ell}{\ell!} z^\ell
\]

where \(r^\ell = r(r - 1) \cdots (r - \ell + 1)\) denotes the falling factorial. (If we like, we can alternatively use the notation \(\binom{r}{\ell} = \frac{r^\ell}{\ell!}\), which is a well-defined polynomial in the indeterminate \(r\).) We obtain

\[
a_n(rq) = \sum_{\ell=0}^{n} \frac{r^\ell}{\ell!} \sum_{\frac{n_1, \ldots, n_\ell}{\sum n_j = n}} \binom{n}{n_1, \ldots, n_\ell} \prod_{j=1}^{\ell} a_{n_j}(q) . \quad (2.7)
\]

In view of the identity \((-r)^\ell = (-1)^\ell r^\ell\) where \(r^\ell = r(r + 1) \cdots (r + \ell - 1) = (r + \ell - 1)^\ell\) denotes the rising factorial, we also have

\[
a_n(-rq) = \sum_{\ell=0}^{n} \frac{(-1)^\ell r^\ell}{\ell!} \sum_{\frac{n_1, \ldots, n_\ell}{\sum n_j = n}} \binom{n}{n_1, \ldots, n_\ell} \prod_{j=1}^{\ell} a_{n_j}(q) . \quad (2.8)
\]

Since both sides of the identities (2.7)/(2.8) are polynomials in \(r\), we can specialize these identities to \(r\) integer or rational, or more generally to \(r\) being any element of the ring \(R\). If \(r\) is a positive integer, the sum in (2.7) can obviously be restricted to \(\ell \leq r\). Slightly (but not much) less trivially, if \(r\) is a positive integer, then by using

\[
\frac{r^\ell}{\ell!} = \frac{(r + \ell - 1)!}{\ell!(r - 1)!} = \frac{(\ell + 1)^{r-1}}{(r-1)!}
\]

(2.9)
we can rewrite (2.8) as

\[ a_n(-rq) = \sum_{\ell=0}^{|n|} (-1)^\ell \frac{(\ell + 1)^{|n|} - 1}{(r-1)!} \sum_{n_1, \ldots, n_\ell \neq 0 \atop \sum j = n} \left( \begin{array}{c} n \\ n_1, \ldots, n_\ell \end{array} \right) \prod_{j=1}^\ell a_{n_j}(q), \]  

(2.10)

in which the coefficient \((\ell + 1)^{|n|}/(r-1)!)\) is a polynomial of degree \(r - 1\) in \(\ell\). In particular, for \(r = 1\) we have

\[ a_n(-q) = \sum_{\ell=0}^{|n|} (-1)^\ell \sum_{n_1, \ldots, n_\ell \neq 0 \atop \sum n_j = n} \left( \begin{array}{c} n \\ n_1, \ldots, n_\ell \end{array} \right) \prod_{j=1}^\ell a_{n_j}(q). \]  

(2.11)

By formally setting \(r = q_2/q_1\) (this is justifiable if we work in a ring of formal Laurent series in the indeterminate \(q_1\)), we obtain the identity

\[ a_n(q_2) = \sum_{\ell=0}^{|n|} \frac{1}{\ell!} \left( \prod_{j=0}^{\ell-1} (q_2 - j q_1) \right) \sum_{n_1, \ldots, n_\ell \neq 0 \atop \sum n_j = n} \left( \begin{array}{c} n \\ n_1, \ldots, n_\ell \end{array} \right) \prod_{j=1}^\ell \hat{a}_{n_j}(q_1), \]  

(2.12)

which is nice because both sides are manifestly polynomials in the indeterminates \(q_1\) and \(q_2\). Alternatively, for \(n \neq 0\) we can pull out the \(j = 0\) factor and write

\[ \hat{a}_n(q_2) = \sum_{\ell=1}^{|n|} \frac{1}{\ell!} \left( \prod_{j=1}^{\ell-1} (q_2 - j q_1) \right) \sum_{n_1, \ldots, n_\ell \neq 0 \atop \sum n_j = n} \left( \begin{array}{c} n \\ n_1, \ldots, n_\ell \end{array} \right) \prod_{j=1}^\ell \hat{a}_{n_j}(q_1). \]  

(2.13)

Conversely, it is not hard to see that if \(q_1\) is any element of the ring \(R\) and \(\hat{a}(q_1)\) is any sequence, and we define \((a_n(q))_{n \in \mathbb{N}}\) by (2.12), then the latter family satisfies (2.2).

The following special cases of (2.12)/(2.13) are of particular interest:

(a) For \(q_1 = 0\), the identity (2.12) reduces to (2.3).

(b) For \(q_2 = 0\), we obtain the inverse formula (2.4)/(2.5).

(c) For \(q_2 = -q_1\), we obtain the closely related formula (2.11).

It is easy to show that the coefficients \(\{a_n(q)\}_{n \in \mathbb{N}}\) satisfy the identities

\[ \sum_k \binom{n}{k} a_k(q_1) a_{n-k}(q_2) = a_n(q_1 + q_2) \]  

(2.14)

\[ \sum_{k \neq 0} \binom{n}{k} k \hat{a}_k(q_1) a_{n-k}(q_2) = n_i \hat{a}_n(q_1 + q_2) \quad \text{for} \; n \neq 0 \]  

(2.15)
Indeed, (2.14) follows by expanding out the identity $A_{q_1}(x)A_{q_2}(x) = A_{q_1+q_2}(x)$ and extracting the coefficient of $x^n$, while (2.15) follows analogously from

\[
A_{q_2}(x) \left[ x_i \frac{\partial}{\partial x_i} A_{q_1}(x) - \frac{1}{q_1} \right] = x_i \frac{\partial}{\partial x_i} A_{q_1+q_2}(x) - \frac{1}{q_1 + q_2},
\]

which is an easy consequence of (2.2). In particular, specializing (2.15) to $q_i = \{\}$ allows the extracting the coefficient of $x$, which reduces to (2.17) when $q_1 = 0$.

We do not know whether there exist useful analogues of (2.14)/(2.15) with higher powers of $k$ on the left-hand side.

Finally, we can deduce the Abel-type extensions of (2.14)/(2.15):

\[
\sum_k \binom{n}{k} q_1 \tilde{a}_k(q_1 + k \cdot t) q_2 \tilde{a}_{n-k}(q_2 + (n-k) \cdot t) = (q_1 + q_2) \tilde{a}_n(q_1 + q_2 + n \cdot t)
\]

(2.19)

\[
\sum_{k \neq 0} \binom{n}{k} k_i \tilde{a}_k(q_1 + k \cdot t) q_2 \tilde{a}_{n-k}(q_2 + (n-k) \cdot t) = n_i \tilde{a}_n(q_1 + q_2 + n \cdot t)
\]

for $n \neq 0$

(2.20)

where $t = (t_i)_{i \in V}$ are commuting indeterminates and we understand $q_0(q) = 1$. These formulae can be proved by repeated use of the Lagrange inversion formula, once in each variable. For details we refer to the paper of Zeng [70, pp. 225–226]. For further information on classical specializations of (2.19)/(2.20), see [42, 43, 58, 61, 70].

**Remark.** We wonder whether (2.19)/(2.20) might have an extension to identities involving a not-necessarily-diagonal matrix $T = (t_{ij})_{i,j \in V}$ of indeterminates, based on considering the implicit equation

\[
\exp(C(x; T)) = A(\exp(C(x; T))^T x),
\]

(2.21)

which generalizes (1.12). If true, this could be a powerful extension. See Strehl [61] for possibly related work in which a matrix of indeterminates is employed.
3 Application to the multivariate Tutte polynomial

In this section we apply the formulae of Section 2 to deduce some identities for multivariate Tutte polynomials.

3.1 Definitions and basic properties

Let $G = (V, E)$ be a finite undirected graph with vertex set $V \neq \emptyset$ and edge set $E$; loops and multiple edges are allowed unless explicitly stated otherwise. Then the multivariate Tutte polynomial \cite{57} of $G$ is, by definition, the polynomial

$$Z_G(q,v) = \sum_{A \subseteq E} q^{k(A)} \prod_{e \in A} v_e ,$$

(3.1)

where $q$ and $v = (v_e)_{e \in E}$ are commuting indeterminates, and $k(A)$ denotes the number of connected components in the subgraph $(V, A)$. It is also convenient to pull out one factor of $q$ by defining

$$\hat{Z}_G(q,v) = \sum_{A \subseteq E} q^{k(A)-1} \prod_{e \in A} v_e ;$$

(3.2)

this is still a polynomial since $k(A) \geq 1$ for all $A$. Finally, let us make the convention that if $G = \emptyset$ (the graph with empty vertex set and empty edge set), then $Z_\emptyset = 1$ and $\hat{Z}_\emptyset$ is undefined.

If we specialize to $v_e = v$ for all edges $e$, we obtain a two-variable polynomial $Z_G(q,v)$ that is essentially equivalent to the classical Tutte polynomial \cite[section 2.5]{57}.

Note that at $q = 1$ we have the trivial formula

$$Z_G(1,v) = \hat{Z}_G(1,v) = \prod_{e \in E} (1 + v_e) .$$

(3.3)

More interestingly, at $q = 0$ we have the specialization

$$\hat{Z}_G(0,v) = C_G(v) \equiv \sum_{A \subseteq E \atop k(A) = 1} \prod_{e \in A} v_e ,$$

(3.4)

i.e. the generating polynomial of connected spanning subgraphs of $G$.

In statistical physics, $Z_G(q,v)$ is known as the partition function of the $q$-state Potts model \cite{44,68,69} in the Fortuin–Kasteleyn representation \cite{15,26,29}. This arises by virtue of the following identity \cite{15,29}:

\textbf{Theorem 3.1 (Fortuin–Kasteleyn representation of the Potts model \cite{15,29})}

For integer $q \geq 1$, we have

$$Z_G(q,v) = \sum_{\sigma : V - [q]} \prod_{e = ij \in E} \left[ 1 + v_e \delta(\sigma(i), \sigma(j)) \right]$$

(3.5)

where $\delta$ denotes the Kronecker delta.
Theorem 3.3

Let \( G \) (with weights as assigned above) be the set of all graphs \( (V,E) \) in which the weights \( v_i = (v_e)_{e \in E} \) are assigned to the vertices of \( G \) by expanding each vertex \( i \) to a clique consisting of \( n_i \) vertices. That is, the vertex set of \( G'[n] \) is the same as that of \( G[n] \), and the edges of \( G'[n] \) consist of those of \( G[n] \) together with all pairs \( ((i, \alpha), (j, \beta)) \) with \( i \in V, \alpha, \beta \in [n_i] \) and \( \alpha \neq \beta \). Given a set of weights \( \mathbf{v} = (v_e)_{e \in E} \) associated to the edges of \( G \) and another set of weights \( \mathbf{w} = (w_i)_{i \in V} \) associated to the vertices of \( G \), we assign the weight \( v_{ij} \) to each edge \( \langle (i, \alpha), (j, \beta) \rangle \) (\( i \neq j \)) in \( G'[n] \) and the weight \( w_i \) to each edge \( \langle (i, \alpha), (i, \beta) \rangle \) in \( G'[n] \).

Note in particular that if \( n = \mathbf{1}_W \) for some subset \( W \subseteq V \), then \( G[n] = G'[n] = G[W] \), the induced subgraph of \( G \) on \( W \).

The following “master formula” generates the multivariate Tutte polynomials (with weights as assigned above) of all the graphs \( G[n] \) and \( G'[n] \):

**Theorem 3.3** Let \( G = (V,E) \) be a simple graph, and let \( \mathbf{v} = (v_e)_{e \in E} \) and \( \mathbf{w} = (w_i)_{i \in V} \) be indeterminates. We then have the following exponential generating func-
tions:
\[ \sum_n Z_{G[n]}(q, v) \frac{x^n}{n!} = \left( \sum_n \left( \prod_{ij \in E} (1 + v_{ij})^{n_{ij}} \right) \frac{x^n}{n!} \right)^q \]  
(3.7)

\[ \sum_n Z_{G^c[n]}(q, v, w) \frac{x^n}{n!} = \left( \sum_n \left( \prod_{ij \in E} (1 + v_{ij})^{n_{ij}} \right) \left( \prod_{i \in V} (1 + w_i)^{n_i(n_i-1)/2} \right) \frac{x^n}{n!} \right)^q \]  
(3.8)

where all sums run over \( n \in \mathbb{N}^V \).

We remark that the expression in large parentheses on the right-hand side of (3.7) [resp. (3.8)] is the grand partition function for a lattice gas on the graph \( G \) [resp. on the graph \( G^c \) obtained from \( G \) by adjoining a loop at each vertex] in which arbitrary nonnegative integer occupation numbers \( n = (n_i)_{i \in V} \) are allowed, with fugacities \( x \) on the vertices and two-particle Boltzmann weights \( 1 + v_{ij} \) on edges \( ij \) [and two-particle Boltzmann weights \( 1 + w_i \) on the loops]. See e.g. [53, 54] for definitions concerning lattice gases.

When \( G = K_1 \) (the graph with one vertex and no edges), (3.8) reduces to the well-known [6, 17, 19, 63, 65] exponential generating function for the Tutte polynomials of the complete graphs \( K_n \):

\[ \sum_{n=0}^{\infty} Z_n(q, v) \frac{x^n}{n!} = \left( \sum_{n=0}^{\infty} (1 + v)^{n(n-1)/2} \frac{x^n}{n!} \right)^q . \]  
(3.9)

When \( G = K_2 \), (3.7) reduces to the exponential generating function for the Tutte polynomials of the complete bipartite graphs \( K_{n_1, n_2} \):

\[ \sum_{n_1, n_2=0}^{\infty} Z_{n_1, n_2}(q, v) \frac{x^{n_1} y^{n_2}}{n_1! n_2!} = \left( \sum_{n_1, n_2=0}^{\infty} (1 + v)^{n_1 n_2} \frac{x^{n_1} y^{n_2}}{n_1! n_2!} \right)^q , \]  
(3.10)

which in turn specializes for \( v = -1 \) to the well-known [60, Exercise 5.6, pp. 73 and 107–108] exponential generating function for the chromatic polynomials of the complete bipartite graphs:

\[ \sum_{n_1, n_2=0}^{\infty} P_{K_{n_1, n_2}}(q) \frac{x^{n_1} y^{n_2}}{n_1! n_2!} = (e^x + e^y - 1)^q . \]  
(3.11)

More generally, when \( G = K_r \), (3.7) gives the exponential generating function for the Tutte polynomials of the complete \( r \)-partite graphs \( K_{n_1, \ldots, n_r} \).

\[ \text{Unfortunately, this formula is usually written in terms of the classical Tutte polynomial } T_G(x, y), \]  
which is related to \( Z_G(q, v) \) by a change of variables [57, section 2.5] that obscures the very different roles played by \( q \) and \( v \).

\[ (3.11) \] can alternatively be derived from the explicit expression [62] for \( P_{K_{n_1, n_2}}(q) \) by using a well-known Stirling-number identity [25, eq. (7.49)] together with the binomial formula.
Note also that if we only want to know $Z_{G[n]}(q, v)$ for $n \leq 1$ — that is, we want to know $Z_{G[W]}(q, v)$ for subsets $W \subseteq V$ — then it suffices to get correct the terms $n \leq 1$ on the right-hand side of (3.7); all the other terms can be dropped or altered arbitrarily. It follows that

$$Z_{G[W]}(q, v) = \left[ x^1 \right] \left( \sum_{n \leq 1} \left( \prod_{ij \in E} (1 + v_{ij})^{n_i n_j} \right) \frac{x^n}{n!} \right)^q.$$  

(3.12)

Note that the expression in large parentheses is now the grand partition function for a lattice gas with hard-core self-repulsion, i.e. at most one atom can occupy each site. In the special case $v = -1$, this becomes

$$P_{G[W]}(q) = \left[ x^1 \right] I_G(x)^q,$$  

(3.13)

where $I_G(x)$ is the multivariate generating polynomial for independent sets of vertices in $G$. The formula (3.13) was found previously by Lass [35, Proposition 3.1].

Since the formula (3.7) for $G[n]$ is just a specialization of the formula (3.8) for $G'[n]$, obtained by taking $w = 0$, it suffices to prove the latter.

**First Proof of Theorem 3.3.** Since the coefficient of $x^n$ on each side of (3.8) is a polynomial in $q$, it suffices to prove the identity for infinitely many values of $q$ in the ring $R$; in particular, it suffices to prove it for all positive integers $q$. By Theorem 3.1, for integer $q \geq 1$ we have

$$Z_{G'[n]}(q, v, w) = \sum_{\sigma: V(G'[n]) \rightarrow [q]} \prod_{rs \in E(G'[n])} \left[ 1 + v_{rs} \delta(\sigma(r), \sigma(s)) \right] \left( \prod_{i \in V} \prod_{\alpha \in [n_i]} \prod_{\beta \in [n_j]} \left[ 1 + v_{ij} \delta(\sigma(i, \alpha), \sigma(j, \beta)) \right] \right) \times$$  

$$\left( \prod_{i \in V} \prod_{\alpha, \beta \in [n_i]}_{\alpha < \beta} \left[ 1 + w_i \delta(\sigma(i, \alpha), \sigma(i, \beta)) \right] \right).$$  

(3.14a)

(3.14b)

Now, because of the symmetries in the construction of $G'[n]$, the summand in (3.14b) depends only on the numbers $\{n_{i,\tau}\}_{i \in V, \tau \in [q]}$ defined by

$$n_{i,\tau} = \#\{\alpha \in [n_i]: \sigma(i, \alpha) = \tau\},$$  

(3.15)

and we have

$$Z_{G'[n]}(q, v, w) = \sum_{\{n_{i,\tau}\}} \left( \prod_{i \in V} \binom{n_i}{n_{i,1}, \ldots, n_{i,q}} \right) \left( \prod_{ij \in E} \prod_{\tau=1}^q (1 + v_{ij})^{n_{i,\tau} n_{j,\tau}} \right) \times$$  

$$\left( \prod_{i \in V} \prod_{\tau=1}^q (1 + w_i)^{n_{i,\tau} (n_{i,\tau} - 1)/2} \right).$$  

(3.16)
Now multiply by \( x^n/n! \) and sum over \( n \); the sums over the \( n_i, \tau \) now become unrestricted, and the sums for the different values of \( \tau \) decouple; we end up with the product of \( q \) terms each of which is

\[
\sum_n \left( \prod_{ij \in E} (1 + v_{ij})^{n_i n_j} \right) \left( \prod_{i \in V} (1 + w_i)^{n_i(n_i-1)/2} \right) \frac{x^n}{n!}.
\]

(3.17)

\( \square \)

It is instructive to give an alternate proof of Theorem 3.3 in which \( q \) is treated directly as an indeterminate:

**SECOND PROOF OF THEOREM 3.3.** We begin by proving the special case (3.9). From the binomial formula we have

\[
\left( 1 + \sum_{n=1}^{\infty} (1 + v)^n (n-1)/2 \frac{x^n}{n!} \right)^q = 1 + \sum_{b=1}^{\infty} \frac{q^b}{b!} \left( \sum_{n=1}^{\infty} (1 + v)^n (n-1)/2 \frac{x^n}{n!} \right)^b
\]

(3.18a)

\[
= 1 + \sum_{b=1}^{\infty} \frac{q^b}{b!} \sum_{n_1, \ldots, n_b \geq 1} x^{n_1 + \cdots + n_b} \prod_{j=1}^{b} \prod_{i \in \pi_j} (1 + v)_{\pi_j}^{(|\pi_j| - 1)/2}.
\]

(3.18b)

Now write \( n = \sum_{j=1}^{b} n_j \), and consider \( n_1, \ldots, n_b \) as the block sizes in an ordered partition \( \pi = (\pi_1, \ldots, \pi_b) \) of \( [n] \) into \( b \) nonempty blocks. The number of ordered partitions with those block sizes is precisely the multinomial coefficient \( n!/ \prod_{j=1}^{b} n_j! \), so (3.18) is equal to

\[
1 + \sum_{n=1}^{\infty} \frac{x^n}{n!} \sum_{\pi \in \Pi_n^\prime} \frac{|\pi|}{|\pi|!} \prod_{j=1}^{b} (1 + v)_{\pi_j}^{(|\pi_j| - 1)/2},
\]

(3.19)

where \( \Pi_n^\prime \) denotes the set of ordered partitions of \( [n] \), and \( |\pi| \) denotes the number of blocks in the partition \( \pi \). Passing to unordered partitions absorbs the factor \( 1/|\pi|! \) (as these are partitions of a labelled set), and we get

\[
1 + \sum_{n=1}^{\infty} \frac{x^n}{n!} \sum_{\pi \in \Pi_n} q_{\pi}^{|\pi|} \prod_{j=1}^{b} (1 + v)_{\pi_j}^{(|\pi_j| - 1)/2}.
\]

(3.20)

The factor \( (1 + v)_{\pi_j}^{(|\pi_j| - 1)/2} \) corresponds to a sum over (simple undirected) graphs on the vertex set \( \pi_j \), with a weight \( v \) for each edge. We can now reinterpret (3.20) as a sum over (simple undirected) graphs \( H \) on the vertex set \( [n] \), with a weight \( v_{E(H)} \), together with a sum over partitions \( \pi \in \Pi_n \) that are compatible with \( H \) in the sense that each block of \( \pi \) is a union of (vertex sets of) connected components of \( H \). If \( H \) has \( r \) connected components, then these can be grouped into \( b \) nonempty
blocks in \( \binom{r}{b} \) ways (where \( \binom{r}{b} \) is a Stirling number of the second kind); and it is well known [25, eq. (6.10)] that

\[
\sum_{b=1}^{r} \binom{r}{b} q^b = q^r .
\]

Therefore, each graph \( H \) gets a weight \( q^{k(H)|E(H)|} \), and the sum over graphs gives \( Z_n(q, v) \). This proves (3.9).

The more general formulae (3.7)/(3.8) are derived by a variant of this proof in which sums over integers \( n \in \mathbb{N} \setminus \{0\} \) are replaced by sums over multi-indices \( n \in \mathbb{N}^V \setminus \{0\} \). In the one-dimensional case, we were considering partitions of \([n] \), a collection of \( n \) distinct objects of a single type. We are now working with multi-indices in \( \mathbb{N}^V \), and so we will be partitioning collections of objects of \(|V| \) different types. We begin with some notation. Given \( n = (n_i)_{i \in V} \in \mathbb{N}^V \), we write \([n]\) for the set of ordered pairs \( \{(i, \alpha): i \in V \text{ and } \alpha \in \{n_i\}\} \). Thus \(|[n]| = \sum_{i \in V} n_i\). We shall think of the subset \([n]_i := \{(i, \alpha): \alpha \in \{n_i\}\} \) as a copy of \([n_i]\) with type \( i \); thus, \([n]\) is a collection of \( n \) objects, with \( n_i \) objects of type \( i \) for each \( i \in V \). Note that \( G([n]) \) is simply the complete graph on the vertex set \([n]\). Now, given a partition \( \pi = (\pi_1, \ldots, \pi_k) \) of \([n]\) (with all \( \pi_j \) nonempty), we write \(|\pi| = k\). The block sizes \( B(\pi_j) \) are elements of \( \mathbb{N}^V \setminus \{0\} \) defined by

\[
B(\pi_j) = ([\pi_j] \cap \{n\}_i)_{i \in V} .
\]

Thus \( B(\pi_j) \) lists the number of objects of each type contained in the \( j \)-th block of \( \pi \).

Now let us define the weight

\[
W(n) := \left( \prod_{i' \in E} (1 + v_{i'})^{n_{i'}} \right) \left( \prod_{i \in V} (1 + w_i)^{n_i(n_i - 1)/2} \right) .
\]

The right-hand side of (3.8) is then

\[
\left( 1 + \sum_{n \neq 0} W(n) \frac{x^n}{n!} \right)^q = 1 + \sum_{b \geq 1} \frac{q^b}{b!} \left( \sum_{n \neq 0} W(n) \frac{x^n}{n!} \right)^b
\]

\[
= 1 + \sum_{b \geq 1} \frac{q^b}{b!} \sum_{n_1, \ldots, n_b \neq 0} \frac{x^{\sum_{j=1}^{b} n_j}}{\prod_{j=1}^{b} n_j!} \prod_{j=1}^{b} W(n_j) .
\]

Now let \( n = \sum_{j=1}^{b} n_j \), and consider \( n_1, \ldots, n_b \) as the block sizes in an ordered partition \( \pi \) of \([n]\) into \( b \) nonempty blocks. The number of ordered partitions with those block sizes is the (multidimensional) multinomial coefficient \( n! / \prod_{j=1}^{b} n_j! \), so (3.24) is equal to

\[
1 + \sum_{n \neq 0} \frac{x^n}{n!} \sum_{\pi} \frac{q^{|\pi|}}{|\pi|!} \prod_{j=1}^{b} W(B(\pi_j)) ,
\]

where the second sum is over ordered partitions of \([n]\). Passing to unordered partitions, this becomes

\[
1 + \sum_{n \neq 0} \frac{x^n}{n!} \sum_{\pi} q^{|\pi|} \prod_{j=1}^{b} W(B(\pi_j)) .
\]
The factor \( W(B(\pi_j)) \) corresponds to a sum over graphs with vertex set \( \pi_j \), such that edges within \([n]_i\) have weight \( w_i \) and edges between \([n]_i\) and \([n]_j\) have weight \( v_{ijr} \). As before, we can reinterpret (3.26) as a sum over graphs \( H \) with vertex set \([n]\), with these same edge weights. The final step of the argument — summing over partitions \( \pi \) that are compatible with \( H \) — is identical to that in the one-dimensional case: it makes no difference whether the vertex set is \([n]\) or \([n]\). We therefore see that each graph \( H \) gets weight \( q^{k(H)} \) times the product of edge weights, and we are done. □

### 3.3 Consequences for \( Z_G(q, v) \)

In view of Theorem 3.3, we can apply all the results of Section 2 with the identifications

\[
\begin{align*}
\alpha_n(q) &= Z_{G[n]}(q, v, w) \\
\tilde{a}_n(q) &= \tilde{Z}_{G[n]}(q, v, w) \\
c_n &= C_{G[n]}(v, w) \\
a_n(1) &= \left( \prod_{ij \in E} (1 + v_{ij})^{n_i n_j} \right) \left( \prod_{i \in V} (1 + w_i)^{n_i(n_i-1)/2} \right)
\end{align*}
\]

We refrain from writing out all the formulae, which are obtained by substituting (3.27a–d) into (2.3), (2.4)/(2.5), (2.7)–(2.13), (2.14), (2.15), (2.17), (2.18), (2.19) and (2.20). Let us simply show a few important results that arise from the partition formula (2.7)/(2.12) and from the convolution formula (2.14)–(2.15).

#### 3.3.1 Partition formulae

By specializing (2.7)/(2.12) to \( n = 1 \), we can obtain a partition formula that expresses the multivariate Tutte polynomial of \( G \) at \( q = q_2 \) in terms of the multivariate Tutte polynomials of induced subgraphs of \( G \) at \( q = q_1 \), for arbitrary choices of \( q_1 \) and \( q_2 \):

**Proposition 3.4** Let \( G = (V, E) \) be a finite loopless graph. Then

\[
Z_G(q_2, v) = \sum_{\pi \in \Pi(V)} (q_2/q_1)^{\left| \pi \right|} \prod_{B \in \pi} Z_{G[B]}(q_1, v),
\]

where the sum runs over (unordered) partitions \( \pi \) of the vertex set \( V \), the product runs over blocks \( B \) of \( \pi \), and \( G[B] \) denotes the induced subgraph of \( G \) on the vertex set \( B \).\(^{15}\) Equivalently we can write

\[
Z_G(q_2, v) = \sum_{\pi \in \Pi(V)} \left( \prod_{j=0}^{\left| \pi \right| - 1} \left( q_2 - jq_1 \right) \right) \prod_{B \in \pi} \tilde{Z}_{G[B]}(q_1, v)
\]

\(^{15}\)Readers who dislike dividing by indeterminates can reinterpret this formula by writing \( r = q_2/q_1 \) and hence \( q_2 = rq_1 \), as in (2.7).
or

\[ \hat{Z}_G(q_2, v) = \sum_{\pi \in \Pi(V)} \left( \prod_{j=1}^{\vert \pi \vert - 1} (q_2 - jq_1) \right) \prod_{B \in \pi} \hat{Z}_{G[B]}(q_1, v). \] (3.30)

**Proof.** Specializing (2.7) [or equivalently (2.12)] to \( n = 1 \), we obtain a sum over ordered partitions \( \pi = (\pi_1, \ldots, \pi_\ell) \) of \( V \) into \( \ell \) nonempty blocks. Passing from ordered to unordered partitions, we get a factor \( \ell! \) that cancels the \( 1/\ell! \) in (2.7)/(2.12). \( \square \)

Proposition 3.4 is very powerful because we are free to choose \( q_1 \) as we please; then \( Z_G(q_2, v) \) can be written in terms of \( Z_{G[B]}(q_1, v) \). The two most important special cases are \( q_1 = 0 \) and \( q_1 = 1 \).

**Case** \( q_1 = 0 \). Taking the limit \( q_1 \to 0 \) in (3.28), or equivalently just setting \( q_1 = 0 \) in (3.29), we obtain

\[ Z_G(q, v) = \sum_{\pi \in \Pi(V)} q^{\vert \pi \vert} \prod_{B \in \pi} C_{G[B]}(v). \] (3.31)

[This formula can alternatively be derived from (2.3) by the same reasoning as used in proving Proposition 3.4.] Of course, (3.31) also has an obvious direct combinatorial proof, based on the definition (3.1): first we classify subsets \( A \subseteq E \) according to the partition \( \pi \) of the vertex set \( V \) that is induced by the connected components of the subgraph \((V, A)\); then we sum over ways of connecting up each component.

**Case** \( q_1 = 1 \). This special case is slightly less obvious, and it is worth stating it explicitly:

**Corollary 3.5** Let \( G = (V, E) \) be a finite loopless graph. Then

\[ Z_G(q, v) = \sum_{\pi \in \Pi(V)} q^{\vert \pi \vert} \prod_{B \in \pi} \prod_{e \in E(G[B])} (1 + v_e) \] (3.32)

where the sum runs over (unordered) partitions \( \pi \) of the vertex set \( V \), the outermost product runs over blocks \( B \) of \( \pi \), and the innermost product runs over edges in the induced subgraph \( G[B] \). In particular,

\[ C_G(v) = \sum_{\pi \in \Pi(V)} (-1)^{\vert \pi \vert - 1} (\vert \pi \vert - 1)! \prod_{B \in \pi} \prod_{e \in E(G[B])} (1 + v_e) \] (3.33)

\[ Z_G(-1, v) = \sum_{\pi \in \Pi(V)} (-1)^{\vert \pi \vert} \vert \pi \vert! \prod_{B \in \pi} \prod_{e \in E(G[B])} (1 + v_e) \] (3.34)

where \( \vert \pi \vert \) denotes the number of blocks in \( \pi \).

Specializing (3.32)–(3.34) to \( v_e = -1 \) for all edges \( e \), we have:

\[ \text{Specializing (3.32)–(3.34) to } v_e = -1 \text{ for all edges } e, \text{ we have:} \]

\[ \text{The case } q_1 = -1 \text{ is also of interest, as it is related to acyclic orientations. See Lass [35] for some interesting material that may be relevant in the present context.} \]
Corollary 3.6 Let $G = (V, E)$ be a finite loopless graph with $|V| = n$. Then:

$$P_G(q) = \sum_{k=1}^{n} q^k Q_G(k)$$  \hspace{1cm} (3.35)

$$P'_G(0) = C_G(-1) = \sum_{k=1}^{n} (-1)^{k-1} (k-1)! Q_G(k)$$  \hspace{1cm} (3.36)

$$P_G(-1) = \sum_{k=1}^{n} (-1)^{k} k! Q_G(k)$$  \hspace{1cm} (3.37)

where $Q_G(k)$ denotes the number of partitions of $V$ into $k$ nonempty independent subsets.

Of course, (3.35) is well known and has a trivial direct proof by counting proper $q$-colorings; and (3.36)/(3.37) are immediate corollaries of (3.35).

Let us conclude by giving two direct combinatorial proofs of the fundamental Proposition 3.4: one using the subgraph representation (3.1), and the other using the coloring representation (3.5).

**Second Proof of Proposition 3.4.** Use the partition formula (3.31) [which itself had a simple direct combinatorial proof] to expand $Z_G(q_2, v)$ on the left-hand side of (3.28) and to expand each $Z_{G[B]}(q_1, v)$ on the right-hand side. We can then interpret the double sum on the right-hand side as a sum over partitions $\pi$ of $V$, with weight $q_1$ for each block, together with a sum over ways of grouping these blocks into nonempty groups, with a weight $(q_2/q_1)^k$ if we have $k$ groups. Using the identity

$$\sum_{k=1}^{n} \binom{n}{k} (q_2/q_1)^k = (q_2/q_1)^n$$  \hspace{1cm} (3.38)

where $n = |\pi|$, we get exactly the expression on the left-hand side. \hspace{1cm} □

It will not escape the reader’s notice that the argument using (3.38) is identical to the one given earlier using (3.21).

**Third Proof of Proposition 3.4.** Since both sides of (3.28) are polynomials in $q_1$ and $q_2$, it suffices to prove the identity for all pairs of positive integers $q_1, q_2$ such that $r = q_2/q_1$ is also an integer. We shall do this using Theorem 3.1. Consider a (not-necessarily-proper) coloring $\sigma: V \to [q_2]$. Fix a bijection $[q_2] \simeq [q_1] \times [r]$ and write $\sigma = (\tau, \psi)$ where $\tau: V \to [q_1]$ and $\psi: V \to [r]$. We then trivially have

$$Z_G(q_2, v) = \sum_{\sigma: V \to [q_2]} \prod_{e=ij \in E} \left[ 1 + v_e \delta(\sigma(i), \sigma(j)) \right]$$  \hspace{1cm} (3.39a)

$$= \sum_{\psi: V \to [r]} \sum_{\tau: V \to [q_1]} \prod_{e=ij \in E} \left[ 1 + v_e \delta(\tau(i), \tau(j)) \delta(\psi(i), \psi(j)) \right].$$  \hspace{1cm} (3.39b)
The map \( \psi \) induces a partition \( \pi_\psi \) of \( V \) into its nonempty color classes, and the remaining sum over \( \tau \) gives (by Theorem 3.1 again) \( \prod_{B \in \pi_\psi} Z_{G[B]}(q_1, v) \). On the other hand, each partition \( \pi \) of \( V \) arises in this way from \( \frac{r}{|\pi|} \) different colorings \( \psi \), since we have \( r \) choices to color the lexicographically first block of \( \pi \), \( r - 1 \) choices for the lexicographically second block, and so forth. This proves (3.28). □

Important note: The formulae in this subsection — notably (3.33) together with the \( q = 1 \) case of (3.31) — are strongly reminiscent of Möbius inversion on the lattice of partitions \( \Pi(V) \). This is not an accident. In fact, the formula (3.30) is a special case of a “\( q_1-q_2 \) generalization” of Möbius inversion that we present in Appendix A. We are grateful to an anonymous referee for drawing our attention to the connection of these formulae with Möbius inversion and for challenging us to find the underlying general principle.

3.3.2 Convolution formulae

In a similar way we can obtain convolution formulae for the multivariate Tutte polynomial by specializing (2.14)–(2.15):

**Proposition 3.7** Let \( G = (V, E) \) be a finite loopless graph. Then

\[
Z_G(q_1 + q_2, v) = \sum_{W \subseteq V} Z_{G[W]}(q_1, v) Z_{G[V \setminus W]}(q_2, v). \tag{3.40}
\]

Moreover, for each \( i \in V \) we have

\[
\hat{Z}_G(q_1 + q_2, v) = \sum_{W \subseteq V \atop W \ni i} \hat{Z}_{G[W]}(q_1, v) Z_{G[V \setminus W]}(q_2, v) \tag{3.41}
\]

and in particular

\[
Z_G(q, v) = \sum_{W \subseteq V \atop W \ni i} q C_{G[W]}(v) Z_{G[V \setminus W]}(q, v). \tag{3.42}
\]

We also have

\[
|V| Z_G(q_2, v) = \sum_{\emptyset \neq W \subseteq V} \left[ (q_1 + q_2)|W| - q_1|V| \right] \hat{Z}_{G[W]}(q_1, v) Z_{G[V \setminus W]}(q_2, v). \tag{3.43}
\]

**Proof.** (3.40) and (3.41) are just (2.14) and (2.15), respectively, specialized to \( n = 1 \). Further specializing the latter to \( q_1 = 0 \), we obtain (3.42). Finally, (3.43) is obtained by subtracting \( (q_1 + q_2) \times (3.41) \) from (3.40) and summing over \( i \in V \). □

For completeness, let us give a simple direct proof of (3.41). [(3.40) is similar but easier, and is left as an exercise for the reader.]
**Alternate Proof of Proposition 3.7.** From the definition (3.2) we have

\[ \hat{Z}_G(q_1 + q_2, v) = \sum_{A \subseteq E} (q_1 + q_2)^{k(A)-1} \prod_{e \in A} v_e. \]  

(3.44)

The factor \((q_1 + q_2)^{k(A)-1}\) can be handled by choosing, for each connected component of \((V, A)\) other than the component containing the distinguished vertex \(i\), to color it either "1" or "2", with a corresponding factor \(q_1\) or \(q_2\), and summing over all such choices. Now define \(W \subseteq V\) to be the vertex set corresponding to the union of the components colored "1" together with the component containing \(i\). By construction, \(W\) is compatible with \(A\) in the sense that \(A\) has no edges connecting \(W\) to \(V \setminus W\). Moreover, every \(W \ni i\) compatible with \(A\) is obtained exactly once by some choice of colors "1" and "2". On the other hand, the right-hand side of (3.41) is given precisely by such a sum over compatible pairs \((W, A)\) [the \(\hat{Z}_G[W](q_1, v)\) accounts for the fact that the component containing \(i\) carries no color and hence no factor \(q_1\)]. □

We do not know whether the Abel-type extensions (2.19)/(2.20), when applied to the multivariate Tutte polynomial, are of any interest.

### 3.4 Specialization to the complete graphs

Let us now take \(G\) to be the complete graph \(K_n\), with all the edge weights \(v_e\) set equal to the same value \(v\). We write \(Z_n(q, v), \hat{Z}_n(q, v)\) and \(C_n(v)\) for the corresponding polynomials.

#### 3.4.1 Partition formulae

Specializing (3.28), we obtain the general identity

\[ Z_n(q_2, v) = \sum_{\pi \in \Pi_n} (q_2/q_1)^{|\pi|} \prod_{i=1}^{\ell(\pi)} Z_{|\pi_i|}(q_1, v), \]  

(3.45)

where the sum runs over (unordered) partitions \(\pi\) of \([n]\), say \(\pi = \{\pi_1, \ldots, \pi_\ell\}\), and \(|\pi|\) denotes the number of blocks in \(\pi\) (i.e., \(|\pi| = \ell\)). Special cases of (3.45) arise at particular values of \(q_1\):

**Case \(q_1 = 0\).** Specializing (3.31), we obtain the trivial identity

\[ Z_n(q, v) = \sum_{\pi \in \Pi_n} q^{|\pi|} \prod_{i=1}^{\ell(\pi)} C_{|\pi_i|}(v). \]  

(3.46)
**Case \( q_1 = 1 \).** Specializing (3.32)–(3.34), we obtain the less trivial relations

\[
Z_n(q, v) = \sum_{\pi \in \Pi_n} q^{\pi} (1 + v)^{n(n-1)/2 - \|\pi\|} \tag{3.47}
\]

\[
C_n(v) = \sum_{\pi \in \Pi_n} (-1)^{|\pi|-1} \left( |\pi| - 1 \right)! (1 + v)^{n(n-1)/2 - \|\pi\|} \tag{3.48}
\]

\[
Z_n(-1, v) = \sum_{\pi \in \Pi_n} (-1)^{|\pi|} |\pi|! (1 + v)^{n(n-1)/2 - \|\pi\|} \tag{3.49}
\]

where

\[
\|\pi\| = \sum_{1 \leq i < j \leq \ell} \, |\pi_i| \, |\pi_j| = \frac{1}{2} \left( n^2 - \sum_{i=1}^{\ell} |\pi_i|^2 \right) \tag{3.50}
\]

denotes the number of “cross-edges” in \( \pi \), i.e. the number of edges in the complete \( \ell \)-partite graph with vertex classes \( \pi_1, \ldots, \pi_\ell \). Equivalently,

\[
\frac{n(n-1)}{2} - \|\pi\| = \sum_{i=1}^{\ell} |\pi_i| (|\pi_i| - 1) \tag{3.51}
\]

is the number of “internal edges” in \( \pi \). The formulae (3.47)–(3.49) will play an important role in our study of the large-\( n \)-asymptotics of \( C_n(v) \) and \( Z_n(q, v) \) at complex \( v \) [55].

### 3.4.2 Convolution formulae

Specializing (3.40)–(3.43) and exploiting the symmetries of the complete graph, we obtain

\[
Z_n(q_1 + q_2, v) = \sum_{k=0}^{n} \binom{n}{k} Z_k(q_1, v) Z_{n-k}(q_2, v) \tag{3.52}
\]

\[
\hat{Z}_n(q_1 + q_2, v) = \sum_{k=1}^{n} \binom{n-1}{k-1} \hat{Z}_k(q_1, v) Z_{n-k}(q_2, v) \quad \text{for } n \geq 1 \tag{3.53}
\]

\[
Z_n(q, v) = \sum_{k=1}^{n} \binom{n-1}{k-1} q C_k(v) Z_{n-k}(q, v) \quad \text{for } n \geq 1 \tag{3.54}
\]

\[
Z_n(q_2, v) = \sum_{k=1}^{n} \left[ \binom{n-1}{k-1} (q_1 + q_2) - \binom{n}{k} q_1 \right] \hat{Z}_k(q_1, v) Z_{n-k}(q_2, v) \quad \text{for } n \geq 1 \tag{3.55}
\]

On the other hand, these are just the one-dimensional identities (1.5), (1.6), (1.9) and (1.10) applied to the family \( a_n(q) = Z_n(q, v) \), which is indeed of the required form (1.2) by virtue of the generating-function formula (3.9).
The formula (3.54) can be used to compute the $Z_n(q, v)$ inductively given the $C_k(v)$. On the other hand, if we specialize (3.54) to $q = 1$ and use (3.3), we obtain the identity

$$(1 + v)^{n(n-1)/2} = \sum_{k=1}^{n} \binom{n-1}{k-1} C_k(v) (1 + v)^{(n-k)(n-k-1)/2} \quad \text{for } n \geq 1 \quad (3.56)$$

or equivalently

$$C_n(v) = (1 + v)^{n(n-1)/2} - \sum_{k=1}^{n-1} \binom{n-1}{k-1} C_k(v) (1 + v)^{(n-k)(n-k-1)/2} \quad \text{for } n \geq 1,$$

which can be used to compute the $C_n(v)$ inductively ab initio. We call (3.56)/(3.57) the “linear” identity for $C_n(v)$. It goes back at least to Leroux [37, eq. (3.3)] and is probably much older; it can be proven by an easy direct argument based on considering the size $k$ of the connected component containing a fixed vertex. [The same argument proves (3.54).]

Alternatively, if we specialize (3.55) to $q_1 = 1$ and use (3.3), we obtain

$$Z_n(q, v) = \sum_{k=1}^{n} \left[ \binom{n-1}{k-1}(1 + q) - \binom{n}{k} \right] (1 + v)^{k(k-1)/2} Z_{n-k}(q, v) \quad \text{for } n \geq 1 \quad (3.58)$$

which allows us to go directly from $Z_n(1, v) = (1 + v)^{n(n-1)/2}$ to $Z_n(q, v)$ without passing through $C_n(v)$. We can also rewrite (3.58) as

$$\hat{Z}_n(q, v) = (1 + v)^{n(n-1)/2} + \sum_{k=1}^{n-1} \left[ \binom{n-1}{k} q - \binom{n}{k} \right] (1 + v)^{(n-k)(n-k-1)/2} \hat{Z}_k(q, v) \quad \text{for } n \geq 1 \quad (3.59)$$

which manifestly generalizes (3.57) and reduces to it when $q = 0$.

### 3.5 A generalization

Let $a = \{a_n\}_{n=0}^{\infty}$ be an arbitrary sequence of coefficients belonging to the ring $R$, satisfying $a_0 = 1$, and define the family of polynomials

$$Z_n(q; a) = \sum_{\pi \in \Pi_n} q^{|\pi|} \prod_{i=1}^{|\pi|} a_{|\pi_i|} \quad (3.60)$$

with the convention $Z_0 = 1$. Note that $Z_n(1; a) = a_n$. This definition generalizes (3.47)/(3.51), and if we specialize to $a_n = (1 + v)^{n(n-1)/2}$ we obtain $Z_n(q, v)$.

A simple counting argument shows that

$$Z_n(q; a) = \sum_{b=0}^{n} \frac{q^b}{b!} \sum_{n_1, \ldots, n_b \geq 1, \sum n_i = n} \binom{n}{n_1, \ldots, n_b} \prod_{i=1}^{b} a_{n_i} \quad (3.61)$$
Using this to compute the exponential generating function of the \( \{ Z_n(q; a) \} \), we find, after a short calculation using the binomial series, that

\[
\sum_{n=0}^{\infty} \frac{x^n}{n!} Z_n(q; a) = \left( \sum_{n=0}^{\infty} \frac{x^n}{n!} a_n \right)^q.
\]

(3.62)

In other words, the family \( \{ Z_n(q; a) \} \) is of the form \( \{ a_n(q) \} \) defined in (1.2), with \( a_n(1) = a_n \). But this should hardly be surprising, as (3.61) is simply the one-dimensional case of (2.12) with \( q_2 = q \) and \( q_1 = 1 \). We have thus come full circle.

Likewise, the recursion

\[
Z_n(q; a) = q \sum_{k=1}^{n} \binom{n-1}{k-1} a_k Z_{n-k}(q-1; a)
\]

(3.63)

can be proven from (3.60) by an easy direct argument based on considering the size \( k \) of the block of \( \pi \) containing some fixed element of \( [n] \). But this identity is nothing other than (1.11) specialized to \( q_1 = 1 \) and \( q_2 = q - 1 \).

### 3.6 A related problem

Suppose we try a definition analogous to (3.60), but with ordinary powers \( q^{|\pi|} \) in place of falling factorials \( q^{\pi} \). That is, let \( c = \{ c_n \}_{n=1}^{\infty} \) be an arbitrary sequence of coefficients belonging to the ring \( R \), and define the family of polynomials

\[
Y_n(q; c) = \sum_{\pi \in \Pi_n} q^{|\pi|} \prod_{i=1}^{|\pi|} c_{|\pi_i|}
\]

(3.64)

with the convention \( Y_0 = 1 \). Of course, the factor \( q^{|\pi|} \) is superfluous, because we can simply multiply each \( c_n \) by \( q \), but it is convenient to keep it explicit. This definition generalizes (3.46), and if we specialize to \( c_n = C_n(v) \) we obtain \( Z_n(q, v) \).

A simple counting argument shows that

\[
Y_n(q; c) = \sum_{b=0}^{n} \frac{q^b}{b!} \sum_{\sum n_i = n} \binom{n}{n_1, \ldots, n_b} \prod_{i=1}^{b} c_{n_i}.
\]

(3.65)

Using this to compute the exponential generating function of the \( \{ Y_n(q; c) \} \), we find, after a short calculation using the exponential series, that

\[
\sum_{n=0}^{\infty} \frac{x^n}{n!} Y_n(q; c) = \exp \left( q \sum_{n=1}^{\infty} \frac{x^n}{n!} c_n \right).
\]

(3.66)

In other words, the family \( \{ Y_n(q; c) \} \) is again of the form \( \{ a_n(q) \} \) defined in (1.2). But this should hardly be surprising, as (3.65) is simply the one-dimensional case of (2.3) [i.e. (1.3).] We have again come full circle.
Likewise, the recursion

$$Y_n(q; c) = q \sum_{k=1}^{n} \binom{n-1}{k-1} c_k Y_{n-k}(q; c), \quad (3.67)$$

which can be proven from (3.64) by considering the size $k$ of the block of $\pi$ containing some fixed element of $[n]$, is nothing other than (1.9).

4 Nonlinear identity for the multivariate Tutte polynomial

4.1 General identity

In the preceding section we proved the identities (3.41) and (3.42) for the multivariate Tutte polynomial $Z_G(q, v)$, which are based on choosing a single distinguished vertex $i$. We shall now prove a different identity that is based on choosing a pair of distinguished vertices $i, j$. Unlike the identities discussed in the preceding section, this one relies on the graphical structure of $Z_G(q, v)$ and does not appear to generalize to arbitrary families $\{a_n(q)\}$ of the type (1.2).

So let $G = (V, E)$ be a finite undirected graph with $|V| \geq 2$, and let $i, j \in V$ with $i \neq j$. We then have the following identity:

**Theorem 4.1** Let $G = (V, E)$ be a finite graph, and let $i, j \in V$ with $i \neq j$. Then

$$Z_G(q, v) = \sum_{W \subseteq V \setminus \{i, j\}} \left[ q - 1 + \prod_{e \in E(W, j)} (1 + v_e) \right] C_{G[W]}(v) Z_{G[V \setminus W]}(q, v) \quad (4.1)$$

where $E(W, j)$ denotes the set of all edges with one endpoint in $W$ and the other endpoint at $j$. In particular,

$$C_G(v) = \sum_{W \subseteq V \setminus \{i, j\}} \left[ \prod_{e \in E(W, j)} (1 + v_e) - 1 \right] C_{G[W]}(v) C_{G[V \setminus W]}(v). \quad (4.2)$$

We do not know whether there exists a generalization of (4.1) involving $q_1$ and $q_2$ (rather than just $q_1 = 0$).

The proof of Theorem 4.1 is based on looking at the connected component of $i$ in the induced subgraph where $j$ is deleted:

**Proof.** Start from the definition $Z_G(q, v) = \sum_{A \subseteq E} q^{k(A)} \prod_{e \in A} v_e$. Let $G' = (V, A)$ and $G'' = G' \setminus j$, and let $W$ be the vertex set of the connected component of $G''$ containing $i$. Let us now sum over all $A \subseteq E$ that give rise in this way to a specified set $W \subseteq V$, and let us split this sum into two parts according as $A$ does or does not contain at
least one edge from \(j\) to \(W\). If \(A\) does not contain such an edge, then \(W\) is a connected component of \(G'\), giving rise to a factor \(q\), and we get \(qC_G[w](v)Z_{G[V\setminus W]}(q,v)\). On the other hand, if \(A\) contains at least one such edge, then \(W\) forms part of the connected component of \(j\) (\(\in V\setminus W\)) in \(G'\); hence there is no factor \(q\), but there is a factor \(v_e\) for each edge \(e\) in the (nonempty) subset \(A\cap E(W,j)\). Summing over all such nonempty subsets of \(E(W,j)\), we get

\[
\left[ \prod_{e \in E(W,j)} (1 + v_e) - 1 \right] C_G[w](v)Z_{G[V\setminus W]}(q,v) .
\]

(4.3)

Putting everything together gives (4.1). Specialization to \(q = 0\) yields (4.2). □

There is also a variant of (4.1) in which the right-hand side is completely expanded out. For notational simplicity we shall assume that \(G\) has no loop at the distinguished vertex \(j\). (In the general case one must multiply by a factor \(1 + v_e\) for each loop \(e\) at \(j\).)

**Proposition 4.2** Let \(G = (V,E)\) be a finite graph, let \(j \in V\), and suppose that \(G\) has no loop at \(j\). Then

\[
\hat{Z}_G(q,v) = \sum_{\pi \in \Pi(V \setminus \{j\})} \prod_{B \in \pi} \left[ q - 1 + \prod_{e \in E(B,j)} (1 + v_e) \right] C_G[B](v)
\]

(4.4)

where the sum runs over (unordered) partitions \(\pi\) of \(V \setminus \{j\}\), and the product runs over blocks \(B\) of \(\pi\). In particular,

\[
C_G(v) = \sum_{\pi \in \Pi(V \setminus \{j\})} \prod_{B \in \pi} \left[ \prod_{e \in E(B,j)} (1 + v_e) - 1 \right] C_G[B](v)
\]

(4.5)

**Proof.** In (3.2), consider a term \(A \subseteq E\), and let \(G' = (V,A)\) and \(G'' = G' \setminus j\). Let \(\pi\) be the partition of \(V \setminus \{j\}\) into vertex sets of connected components of \(G''\). We can recover \(G'\) from \(G''\) by adjoining, for each block \(B\) of \(\pi\), zero or more edges from the set \(E(B,j)\). If we adjoin zero edges, we get an extra factor \(q\) because \(B\) becomes the vertex set of a connected component of \(G'\) that is distinct from the component containing \(j\); if we adjoin one or more edges, we get no such factor. This proves (4.4). Specialization to \(q = 0\) yields (4.5). □

When \(v_e = v\) for all edges \(e\), the formulae (4.4) and (4.5) can be found in Gessel [17, Theorems 13 and 10]. The special case of (4.5) in which \(v_e = -1\) for all \(e\) was also found by Borgs [8] and used recently by him [9, Lemma 3.2] to bound the complex zeros of chromatic polynomials (a variant of the proof in [56]). Indeed, we were led to formulate (4.4)/(4.5) by meditating on Borgs’ special case, oblivious to the fact that they had already been essentially found by Gessel!
Finally, let us use (4.2) to prove an interesting inequality concerning the polynomials $C_G(v)$. Let
\[ c(A) = |A| - |V| + k(A) \]  
be the cyclomatic number of the subgraph $(V, A)$, and let us define the generalized connected sum
\[ C_G(v, \lambda) = \sum_{A \subseteq E \atop k(A) = 1} \lambda^{c(A)} \prod_{e \in A} v_e \]  
(4.7a)
\[ = \lambda^{-(|V|-1)} C_G(\lambda v) . \]  
(4.7b)
Of course, (4.7b) shows that $C_G(v, \lambda)$ contains no more information than $C_G(v)$; it is simply a convenient way of scaling all the variables $v_e$ simultaneously while removing a factor $\lambda^{|V|-1}$. In particular, $C_G(v, \lambda)$ interpolates between the spanning-tree sum ($\lambda = 0$) and the connected-spanning-subgraph sum ($\lambda = 1$). We then have the following result [56, Remark 2 in Section 4.1] [53, Proposition 2.5]:

**Proposition 4.3** Let $G = (V, E)$ be a finite graph ($V \neq \emptyset$) equipped with real edge weights $v = (v_e)_{e \in E}$ satisfying $-1 \leq v_e \leq 0$ for all $e \in E$. Then
\[ (-1)^{\ell+|V|-1} \frac{\partial^\ell}{\partial \lambda^\ell} C_G(v, \lambda) \geq 0 \]  
(4.8)
on $0 \leq \lambda \leq 1$, for all integers $\ell \geq 0$.

This inequality was proven in [53,56] using a “partitionability” method going back to Penrose [41]. Here we prove it using the recursion (4.2):

**Proof of Proposition 4.3.** By induction on $|V|$. When $|V| = 1$, $G$ necessarily consists of zero or more loops attached to the sole vertex, so
\[ C_G(v, \lambda) = \prod_{e \in E} (1 + \lambda v_e) . \]  
(4.9)
Using $v_e \leq 0$ and $1 + \lambda v_e \geq 0$, it is easy to see that (4.8) holds.

Now assume that $|V| \geq 2$. Replacing $v$ by $\lambda v$ in (4.2) and using (4.7b), we obtain
\[ C_G(v, \lambda) = \sum_{W \subseteq V \atop W \ni i, W \not\ni j} \lambda^{-1} \left[ \prod_{e \in E(W, j)} (1 + v_e) - 1 \right] C_G[W](v, \lambda) C_G[V \setminus W](v, \lambda) \]  
(4.10a)
\[ = \sum_{W \subseteq V \atop W \ni i, W \not\ni j} \left( \sum_{\emptyset \neq B \subseteq E(W, j)} \lambda^{|B|-1} \prod_{e \in B} v_e \right) C_G[W](v, \lambda) C_G[V \setminus W](v, \lambda) . \]  
(4.10b)

\[ \text{For the partitionability method (which applies to matroids as well as graphs), see also [7, 19] and the other references mentioned in [53, Section 2.2].} \]
Now apply $\partial^\ell / \partial \lambda^\ell$ to both sides: on the right-hand side we will have terms in which $\ell_1$ derivatives act on $\sum \lambda^{ |B|-1 } \prod v_e$, $\ell_2$ act on $C_{G[W]}(v, \lambda)$, and $\ell_3$ act on $C_{G[V \setminus W]}(v, \lambda)$, where $\ell_1 + \ell_2 + \ell_3 = \ell$. The induction hypothesis is applicable because $1 \leq |W| \leq |V| - 1$. So it suffices to check that

$$
(-1)^{\ell_1-1} \frac{\partial^{\ell_1}}{\partial \lambda^{\ell_1}} \left( \sum_{\emptyset \neq B \subseteq E(W,j)} \lambda^{ |B|-1 } \prod_{e \in B} v_e \right) \geq 0 .
$$

To prove this, let us order the elements of $E(W,j)$, i.e. consider $E(W,j) \simeq [m]$ where $m = |E(W,j)|$. Then, by singling out the smallest element in each set $B$, we can write

$$
\sum_{\emptyset \neq B \subseteq [m]} \lambda^{ |B|-1 } \prod_{e \in B} v_e = \sum_{i=1}^{m} v_i \prod_{j=i+1}^{m} (1 + \lambda v_j) .
$$

We have $v_i \leq 0$; each $\partial / \partial \lambda$ brings down some factor $v_j \leq 0$; and the undifferentiated factors satisfy $1 + \lambda v_j \geq 0$. So (4.11) holds. □

It is worth remarking that (4.11) is nothing other than Proposition 4.3 specialized to the graph $K_{2m}^2$ consisting of two vertices connected by $m$ parallel edges. Moreover, the identity (4.12) is nothing other than (one version of) the partitionability identity for $K_{2m}^2$.

### 4.2 Specialization to the complete graphs

Specializing (4.1) to the complete graph $K_n$ with equal weights $v$, we obtain

$$
Z_n(q, v) = \sum_{k=1}^{n-1} \binom{n-2}{k-1} [q + (1 + v)^k - 1] C_k(v) Z_{n-k}(q, v) \quad \text{for } n \geq 2
$$

(see [17, eq. (5)] for an equivalent formula). Specializing this to $q = 0$, we obtain

$$
C_n(v) = \sum_{k=1}^{n-1} \binom{n-2}{k-1} [(1 + v)^k - 1] C_k(v) C_{n-k}(v) \quad \text{for } n \geq 2 ,
$$

(see also [5, p. 306, Exercise 4.2.2] for a proof of (4.14) in species language.)

And specializing this latter formula to $v = 1$, we obtain the identity of Riordan, Nijenhuis, Wilf and Kreweras [31, 40, 47] for counting connected graphs. We call (4.14) the “nonlinear” identity for $C_n(v)$.

On the other hand, specializing (4.13) to $q = 1$, dividing both sides by $(1 + v)^{n-1}$ and relabelling $n \rightarrow n + 1$, we recover the “linear” identity (3.56).

The formula (4.14) has also been derived in a different context. Let $T$ be a tree with vertex set $[n]$, rooted at the vertex 1. An inversion of $T$ is an ordered pair $(j, k)$
of vertices such that \( j > k > 1 \) and \( k \) is a descendant of \( j \) (i.e., the path from 1 to \( k \) passes through \( j \)). We define the *inversion enumerator for trees* [20, 31, 38] (see also [10, 17, 19]) to be the polynomial

\[
I_n(y) = \sum_{\text{trees } T \text{ on } [n]} y^{\text{inv}(T)}
\]  

(4.15)

where \( \text{inv}(T) \) denotes the number of inversions in \( T \). This polynomial turns out to be related to \( C_n(v) \) by the beautiful formula [3, 20, 31, 38]

\[
C_n(v) = v^{n-1} I_n(1 + v).
\]  

(4.16)

Now, Mallows, Riordan and Kreweras [31, 38] show that \( I_n(y) \) satisfies the recursion

\[
I_n(y) = \sum_{k=1}^{n-1} \binom{n-2}{k-1} \left( \sum_{j=0}^{k-1} y^j \right) I_k(y) I_{n-k}(y) \quad \text{for } n \geq 2.
\]  

(4.17)

But using (4.16), it is easily seen that (4.17) is equivalent to (4.14).

Let us remark, finally, that even without using (4.15), it follows immediately from the recursion (4.17) [together with the initial condition \( I_1(y) = 1 \)] that the polynomials \( I_n(y) \equiv C_n(y-1)/(y-1)^{n-1} \) have nonnegative (indeed, strictly positive) integer coefficients. On the other hand, the nonnegativity of the derivatives of \( I_n(y) \) at \( y = 0 \) is also a special case of Proposition 4.3.

\section{A generalization of Möbius inversion on the partition lattice}

In this appendix we present an apparently new generalization of Möbius inversion on the lattice of partitions of a finite set, which is inspired by the formulae in Section 3.3.1 and in particular by (3.30), and more generally by (2.13). We refer to [59, Chapter 3] for basic facts about posets and Möbius inversion.

To begin with, let \( P \) be a finite poset. Then the *zeta function* \( \zeta \) on \( P \) is the function \( \zeta : P \times P \to \mathbb{Z} \) defined by

\[
\zeta(x, y) = \begin{cases} 
1 & \text{if } x \leq y \\
0 & \text{if } x \not\leq y
\end{cases}
\]  

(A.1)

(We think of \( \zeta \) as a matrix whose rows and columns are indexed by \( P \).) The *Möbius function* \( \mu \) on \( P \) is the two-sided matrix inverse of \( \zeta \), i.e. it satisfies \( \zeta \mu = \mu \zeta = I \). It can be computed by the recursion

\[
\mu(x, y) = \begin{cases} 
1 & \text{if } x = y \\
- \sum_{x \leq z < y} \mu(x, z) & \text{if } x < y \\
0 & \text{if } x \not\leq y
\end{cases}
\]  

(A.2)
Now let $S$ be a finite set, and let $P$ be the lattice $\Pi(S)$ of partitions of $S$, ordered by refinement. It is well known [59, p. 128] that the M"{o}bius function of $\Pi(S)$ is given by

$$
\mu(\sigma, \pi) = \begin{cases} 
\prod_{i=1}^{k} (-1)^{\lambda_i - 1} (\lambda_i - 1)! & \text{if } \sigma \leq \pi = \{B_1, \ldots, B_k\} \text{ and } B_i \text{ is partitioned into } \lambda_i \text{ blocks in } \sigma \\
0 & \text{if } \sigma \not\leq \pi
\end{cases}
$$

(A.3)

We generalize this as follows: let $q_1$ and $q_2$ be indeterminates, and define

$$
\mu_{q_1, q_2}(\sigma, \pi) = \begin{cases} 
\prod_{i=1}^{k} \prod_{j=1}^{\lambda_i - 1} (q_2 - jq_1) & \text{if } \sigma \leq \pi = \{B_1, \ldots, B_k\} \text{ and } B_i \text{ is partitioned into } \lambda_i \text{ blocks in } \sigma \\
0 & \text{if } \sigma \not\leq \pi
\end{cases}
$$

(A.4)

Let us observe for future reference that

$$
\prod_{j=1}^{m-1} (q_2 - jq_1) = q_1^m q_2^{-1} (q_2/q_1)^{m-1} = q_1^{m-1} (q_2/q_1 - 1)^{m-1}.
$$

(A.5)

Then we have in particular

$$
\mu_{0, 1} = \zeta
$$

(A.6a)

$$
\mu_{1, 0} = \mu
$$

(A.6b)

$$
\mu_{q, q} = I \text{ for all } q
$$

(A.6c)

We shall prove the following generalization of M"{o}bius inversion:

**Theorem A.1** Let $S$ be a finite set, and define the matrices $\mu_{q_1, q_2}$ on $\Pi(S)$ by (A.4). Then

$$
\mu_{q_1, q_2} \mu_{q_2, q_3} = \mu_{q_1, q_3} \quad (\text{matrix multiplication})
$$

(A.7)

We interpret (A.7) as an identity in the polynomial ring $\mathbb{Z}[q_1, q_2, q_3]$, but of course it also holds when $q_1, q_2, q_3$ are specialized to specific integer values (or more generally to specific values in a commutative ring $R$). In particular, M"{o}bius inversion corresponds to the special cases $(q_1, q_2, q_3) = (0, 1, 0)$ and $(1, 0, 1)$.

The proof of Theorem A.1 will be based on the following lemma, which we think is of some interest in its own right. It is probably not new, but we have been unable to find any reference.

**Lemma A.2** Let $m$ be a positive integer, and let $r$ and $s$ be indeterminates. Then

$$
\sum_{\omega \in \Pi_m} r^{\omega} \left( \prod_{B \in \omega} s^{\vert B \vert} \right) = (rs)^m
$$

(A.8)

as an identity in the polynomial ring $\mathbb{Z}[r, s]$. 

30
Let us remark that if one divides (A.8) by \( s^m \) and takes \( s \to \infty \) (or equivalently just extracts the coefficient of \( s^m \)), one obtains the well-known formula (3.21)/(3.38); while if one sets \( r = q/\epsilon, s = \epsilon q \) and takes \( \epsilon \to 0 \), then one obtains the formula

\[
\sum_{\pi \in \Pi_m} \mu(\hat{0}, \pi) q^{\left|\pi\right|} = q^m \quad (A.9)
\]
due to Rota [50, section 9] [59, pp. 128, 162, 187] (here \( \hat{0} \) denotes the partition in which every element is a singleton).

**Proof of Lemma A.2.** It suffices to prove (A.8) for positive integers \( r, s \). Then the right-hand side counts the proper colorings of the complete graph \( K_m \) with \( rs \) colors. But so does the left-hand side, if we use the color set \([r] \times [s]\) and define \( \omega \) to be the partition of \([m]\) in which two vertices are placed in the same block if and only if they receive a color with the same first index. \( \square \)

**Second Proof of Lemma A.2** (suggested independently by Christian Krattenthaler and Richard Stanley). We use the isomorphism of weighted species

\[
\text{Partitions} = \text{Sets} \circ \text{NonemptySets}, \quad (A.10)
\]

where a Set of cardinality \( b \) is given a weight \( r^b \), a NonemptySet of cardinality \( k \) is given a weight \( s^k \), and a partition \( \omega \) is weighted as on the left-hand side of (A.8).\(^{19}\)

The corresponding exponential generating functions are

\[
F(x) = \sum_{b=0}^{\infty} \frac{x^b}{b!} r^b = (1 + x)^r \quad (A.11)
\]

\[
G(x) = \sum_{k=1}^{\infty} \frac{x^k}{k!} s^k = (1 + x)^s - 1 \quad (A.12)
\]

and hence

\[
(F \circ G)(x) = (1 + x)^{rs} = \sum_{m=0}^{\infty} \frac{x^m}{m!} (rs)^m, \quad (A.13)
\]

which proves (A.8) for all \( m \geq 0 \). \( \square \)

**Proof of Theorem A.1.** Let \( \sigma \leq \pi = \{B_1, \ldots, B_k\} \) where \( B_i \) is partitioned into \( \lambda_i \) blocks in \( \sigma \), and let us compute

\[
(\mu_{q_1,q_2} \mu_{q_2,q_3})(\sigma, \pi) = \sum_{\sigma \leq \tau \leq \pi} \mu_{q_1,q_2}(\sigma, \tau) \mu_{q_2,q_3}(\tau, \pi). \quad (A.14)
\]

\(^{19}\)See [5, pp. 44, 86] for this isomorphism with a different weighting. For the reader unfamiliar with the theory of combinatorial species [5], it suffices to observe that a partition of a finite set \( S \) is simply a set of nonempty subsets of \( S \) that disjointly cover \( S \); one can then invoke [60, Theorem 5.1.4] to complete the proof.
The partition $\tau$ is specified by saying, for each $i \in [k]$, how the corresponding $\lambda_i$ blocks of $\sigma$ get grouped in $\tau$. The sum (A.14) will then factorize over $i$, with the $i$th factor given by

$$
\sum_{\omega \in \Pi_{\lambda_i}} \left( \prod_{\alpha=1}^{\mu_i} B_{\alpha}^{-1}(q_2/q_1) \right) \prod_{k=1}^{\mu_i-1} (q_3 - kq_2) = q_1^{\lambda_i} q_3^{-1} \sum_{\omega \in \Pi_{\lambda_i}} \left( \prod_{\alpha=1}^{\mu_i} B_{\alpha}^{-1}(q_2/q_1) \right) (q_3 - q_2)^{\mu_i} = q_1^{\lambda_i} q_3^{-1} (q_3/q_1)^{\lambda_i} \tag{A.15}
$$

by Lemma A.2. $\Box$

**Second Proof of Theorem A.1** (suggested by Richard Stanley). We prove (A.7) for $S = [n]$ simultaneously for all $n \geq 1$, using the interpretation of convolution of multiplicative functions on $\Pi = (\Pi_1, \Pi_2, \ldots)$ in terms of composition of exponential generating functions [60, pp. 7–8]. We first observe that $\mu_{q_1,q_2}$ is a multiplicative function on $\Pi$, with underlying numerical function

$$
f_{q_1,q_2}(m) = \prod_{j=1}^{m-1} (q_2 - jq_1) = q_1^m q_2^{-1}(q_2/q_1)^m \tag{A.16}
$$

and corresponding exponential generating function

$$
F_{q_1,q_2}(x) = \sum_{m=1}^{\infty} f_{q_1,q_2}(m) \frac{x^m}{m!} = q_2^{-1}[1 + q_1 x q_2/q_1 - 1] \tag{A.17}
$$

It is easy to check that

$$
F_{q_2,q_3}(F_{q_1,q_2}(x)) = F_{q_1,q_3}(x) \tag{A.18}
$$

By [60, Theorem 5.1.11], the identities (A.7) for all $n \geq 1$ are an immediate consequence.20 $\Box$

---

20Using [60, Theorem 5.1.11] with the coefficient field $K$ taken to be (say) $\mathbb{R}$, this argument proves (A.7) for $q_1, q_2, q_3 \in \mathbb{R}\setminus\{0\}$, which is more than enough to imply it as a polynomial identity. Alternatively, we can use [60, Theorem 5.1.11] with $K$ taken to be (say) the field $\mathbb{R}(q_1, q_2, q_3)$ of rational functions in the indeterminates $q_1, q_2, q_3$, which yields (A.7) directly as a polynomial identity.
Remark. If we define the diagonal matrix \( D_r \) by

\[
D_r(\sigma, \pi) = \begin{cases} 
|\sigma| & \text{if } \sigma = \pi \\
0 & \text{if } \sigma \neq \pi 
\end{cases}
\] (A.19)

then an easy calculation shows that

\[
D_r \mu_{q_1,q_2} D_r^{-1} = \mu_{rq_1,rq_2} .
\] (A.20)

This is why many things involving \( \mu_{q_1,q_2} \) depend only on the ratio \( q_2/q_1 \) [cf. (3.28)].

We can apply Theorem A.1 as follows: Let \( R \) be a commutative ring, and fix a function \( f : \Pi(S) \to R \) and an element \( q_0 \in R \) (it could be an indeterminate if desired). Now introduce a new indeterminate \( q \), and define \( F_q : \Pi(S) \to R[q] \) by

\[
F_q = f \mu_{q_0,q}
\] (A.21)

or in more detail

\[
F_q(\pi) = \sum_{\sigma \in \Pi(S)} f(\sigma) \mu_{q_0,q}(\sigma, \pi) .
\] (A.22)

By construction we have imposed the “initial condition”

\[
F_{q_0} = f
\] (A.23)

(here \( F_{q_0} \) means of course that the indeterminate \( q \) is replaced by the value \( q_0 \in R \)). Most importantly, Theorem A.1 implies that the \( q \)-dependence of \( F_q \) is “coherent” in the sense that

\[
F_{q_1} \mu_{q_1,q_2} = F_{q_2} .
\] (A.24)

The formula (3.30) is now the special case of (A.24) in which we take \( S = V \),

\[
F_q(\pi) = \prod_{B \in \pi} \hat{Z}_{G[B]}(q,v) ,
\] (A.25)

and we evaluate (A.24) at \( \pi = \hat{1} \) (the partition in which all of \( V \) belongs to a single block). More generally, in place of \( \hat{Z}_{G[B]}(q,v) \) we can use \( \hat{a}_{1_B}(q) \) where \( \{\hat{a}_n(q)\} \) is any family arising as in Section 2; we then obtain (2.13) specialized to \( n = 1 \).\(^{21}\)

The formulae in this appendix seem to be special for the partition lattice. Still, it may not be totally absurd to ask: Might there exist “\( q_1-q_2 \) generalizations” of Möbius inversion for some other posets? Maybe even for some natural class of posets?

---

\(^{21}\)Note also that, in these formulae, we use \( \hat{a}_n(q) \) [or \( c_n \)] only for \( 0 \leq n \leq 1 \).
Acknowledgments

We are grateful to Pierre Leroux for an extremely careful reading of the manuscript and for many suggestions, both substantive and bibliographic. In particular, it is thanks to him that our attention was drawn to [5, Section 3.1] and notably to [5, p. 189, Exercise 3.1.22], from which we learned about the Abel-type extensions (1.16)–(1.19).

We finished the first version of this paper, by unhappy circumstance, on the same day that we learned that Pierre had been struck with a grave illness, to which he succumbed two weeks later. We dedicate this work to his memory.

Finally, we are grateful to an anonymous referee for pointing out the connection of the formulae of Section 3.3.1 with Möbius inversion — which led us to discover the results reported in the Appendix — and to Christian Krattenthaler and Richard Stanley for comments on these results.

This research was supported in part by U.S. National Science Foundation grant PHY–0424082, by U.K. Engineering and Physical Sciences Research Council grant GR/S26323/01, and by a Leverhulme Visiting Professorship.
