**ABSTRACT:** The DGKT vacua are a class of AdS$_4$ flux vacua showing full moduli stabilization, parametric control, and a parametric separation of scales. The particular masses of the moduli remarkably give rise to integer conformal dimensions in the light spectrum of the would-be holographic duals. In this note, we comment on two properties for AdS flux vacua with integer conformal dimensions. First, there are polynomial spacetime-dependent shift symmetries for the moduli. Secondly, the leading scalings of the central charge and the moduli can be directly deduced from the near-horizon geometry of stacks of orthogonally-intersecting D-brane domain walls dual to the unbounded fluxes. This suggests that a dual field theory could be found on this relatively simple set of domain walls. We illustrate this in a couple of examples of AdS$_4$ and AdS$_3$ parametric flux vacua.

**KEYWORDS:** AdS-CFT Correspondence, Flux Compactifications, Superstring Vacua

**ArXiv ePrint:** 2211.04187
1 Introduction

Realistic string theory vacua should have full moduli stabilization and a separation of scales between the Hubble scale $L_H$ and the Kaluza-Klein length scale $L_{KK}$, corresponding to the diameter of the internal manifold,

$$\frac{L_{KK}}{L_H} \ll 1.$$  

(1.1)

The DGKT vacua \cite{1, 2} are a class of $\mathcal{N} = 1$ AdS$_4$ flux vacua with full moduli stabilization, obtained from compactifying massive type IIA string theory on a Calabi-Yau threefold with fluxes and intersecting O6-planes. As there is unbounded flux $|F_4| \sim N$, parametric control

$$g_s \sim N^{-3/4}, \quad \text{vol}_S \sim N^{3/2},$$  

(1.2)

with $g_s$ the string coupling and $\text{vol}_S$ the internal volume in string frame, and parametric scale separation

$$\frac{L_{KK}}{L_H} \sim N^{-1/2}$$  

(1.3)

can be achieved by sending this flux to infinity.

There is however no full 10-dimensional understanding of the backreaction of the O6-planes on the internal geometry \cite{3} (for recent progress on this, see e.g. \cite{4–6}), and scale-separated supersymmetric AdS vacua are conjectured to be in the swampland \cite{7}. Studying the holographic CFT duals is a promising alternative approach for checking the consistency of these AdS vacua \cite{8–10}.
The would-be CFT duals of the DGKT vacua do have some very peculiar properties. First, scale-separated AdS vacua in general should be dual to CFTs with a large gap in the spectrum of single-trace primaries, and such CFTs are unknown [11]. Also, the central charge should scale like

$$c_{4d} \sim N^{9/2},$$

which is a higher scaling than in any known holographic set-up[12, 13], which goes up to $N^3$ [14, 15]. Moreover, the spectrum of light operators, dual to the moduli, would consist fully of integer conformal dimensions [16] (see also [17–20]). The Kähler moduli and dilaton are dual to $h^{1,1}$ operators with $\Delta = 6$ and one operator with $\Delta = 10$. These integers are universal [21, 22]: independent of the values of the fluxes and microscopic details of the Calabi-Yau internal manifold. As there is no extended supersymmetry in these CFTs (3d $\mathcal{N} = 1$), the presence of integers is very surprising and requires an explanation.

In this work we argue that integer dimensions are interesting, with two remarkable properties for AdS flux vacua with integers:

- Moduli fields in AdS flux vacua, dual to light operators with integer conformal dimensions, do have polynomial spacetime-dependent shift symmetries.

- It is possible to obtain the leading scalings of the central charge, string coupling and internal volume from the near-horizon geometry of a large number $N$ of orthogonally-intersecting D-brane domain walls, dual to the unbounded fluxes.

Because these domain walls reproduce the right scalings, it seems that the dual field theory will be the one living on these branes. Therefore, the holographic set-up for these vacua with integer dimensions does seem to be relatively simple and does not differ too much from the well-known AdS$_5 \times S^5$ example [14], where the D3-branes are dual to an unbounded $F_5$-flux and which has an integer $\Delta = 8$ in the light spectrum [23].

We heavily lean on [24] about a domain wall - flux correspondence in AdS$_4$ flux vacua. It is explained there how the fluxes ($F_4$, $H_3$, $F_0$) in DGKT can be interchanged for domain walls (wrapped D4-, NS5- and D8-branes), interpolating between AdS and flat spacetime, and how a AdS$_4 \times T_6$ geometry can be recovered as the near-horizon limit of these domain walls. We will just focus on the three stacks of $N$ orthogonally intersecting D4-branes of this set-up, dual to the unbounded flux $F_4 \sim N$, and observe how the large $N$ scalings can be directly deduced from the near-horizon geometry of these domain walls. For other parametric AdS$_4$ flux vacua with an integer $\Delta = 6$ in the spectrum, we observe how the large $N$ scalings can be derived in a similar way.

Because the space of 2d CFTs is better understood, it might be easier to bootstrap the holographic duals of AdS$_3$ vacua. Scale-separated AdS$_3$ vacua with minimal supersymmetry were found in [25] from compactification of massive IIA string theory on G2 holonomy spaces. The ingredients are very similar as for the DGKT vacua, with unbounded $F_4$-fluxes, and bounded $H_3$- and $F_0$-fluxes in combination with intersecting O6-planes. Now O2-planes are needed as well. Thanks to the unbounded $F_4$-flux, parametric control

$$g_s \sim N^{-3/4}, \quad \text{vol}_S \sim N^{7/4},$$

can be directly deduced from the near-horizon geometry of these domain walls. For other parametric AdS$_3$ flux vacua with an integer $\Delta = 6$ in the spectrum, we observe how the large $N$ scalings can be derived in a similar way.
and parametric scale separation (1.3) are achieved in the $N \to \infty$ limit. The central charge of the CFT$_2$ duals should now be
\[ c_{3d} \sim N^4, \]
and the light spectrum consists of irrational dimensions [26]. In this case, it is not possible to obtain the scalings (1.6), (1.7) from the near-horizon geometry of a set of orthogonally intersecting D4-brane domain walls. This suggests that for vacua with irrational conformal dimensions, a more complicated holographic set-up will be needed.

There are however other AdS$_3$ vacua in IIB string theory [27] for which the holographic brane set-up might be much simpler and more alike the 4d examples with $\Delta = 6$ we discuss. The internal manifold is a G2-structure manifold, and $F_7$- and $F_3$-fluxes are used [27]. Parametric scale separation can not be achieved for these vacua, but by taking $F_7 \sim N$ to be large, parametric control can be obtained. Interestingly, in a two-moduli truncation, the conformal dimensions are integer and rational ($\Delta_1 = 4$ and $\Delta_2 = 20/7$). Moreover, the leading scalings are now obtainable from the near-horizon limit of a stack of $N$ D1-branes, dual to the $F_7$-flux. So despite not showing a separation of scales, an exploration the holographic duals of these vacua, instead of the ones with irrational dimensions [25] mentioned above, might bring us closer to an understanding of the DGKT duals. The properties of the different AdS vacua we discuss are summarized in Table 1.

The outline is as follows. In section 2, the relation between shift symmetries and integer dimensions is explained. Then, in section 3, we first describe how to derive large $N$ scalings from D-brane domain walls in general in section 3.1. We apply this in section 3.2 to the DGKT vacua, both in massive ($F_0 \neq 0$) and in a double T-dual massless ($F_0 = 0$) form. We also briefly touch upon more general parametric AdS$_4$ vacua which have a $\Delta = 6$ in the spectrum. In section 3.3 the large $N$ scalings in IIA and IIB AdS$_3$ vacua are discussed, and we conclude in section 4.

## 2 Polynomial shift symmetries

The conformal dimensions of the light fields in the DGKT CFT duals are [11, 22]
\[ \Delta_\phi = (6, \ldots, 6, 10), \quad \Delta_\alpha = (5, \ldots, 5, 11), \]
for the $h^{1,1}$ and 1 saxions and axions respectively, and
\[ \Delta_\phi = (2, \ldots, 2), \quad \Delta_\alpha = (3, \ldots, 3), \]
for the $h^{2,1}$ complex structure moduli and their axions. All dimensions are integer.

|                      | IIA AdS$_4$ [1] | IIA AdS$_3$ [25] | IIB AdS$_3$ [27] |
|----------------------|----------------|----------------|-----------------|
| parametric control   | yes            | yes            | yes             |
| parametric scale separation | yes          | yes            | no              |
| integer dimension $\Delta = 2d$ | yes          | no             | yes             |
| simple brane set-up  | yes            | no             | yes             |

Table 1. Properties of different parametric AdS vacua in $(d + 1)$ dimensions.
As conformal dimensions in $\text{AdS}_{d+1}/\text{CFT}_d$ are obtained from the masses via a quadratic equation

$$\Delta(\Delta - d) = m^2 R_{\text{AdS}}^2,$$

(2.3)

it is surprising to get integers and one expects there to be a symmetry at work. Massless scalars, with $\Delta = 3$, for example, enjoy a constant shift symmetry. Could there be different shift symmetries for other integers?

For a free massless field in Minkowski space, there is not only the constant shift symmetry

$$\phi \rightarrow \phi + c, \quad c \in \mathbb{R},$$

(2.4)

but also an infinite sequence of shift symmetries that are polynomial in the spacetime coordinates $X^\mu$,

$$\phi \rightarrow \phi + c + c_{\mu} X^\mu + c_{\mu\nu} X^\mu X^\nu + \ldots,$$

(2.5)

where $c_{\mu_1\ldots\mu_k}$ are rank-$k$ symmetric traceless constant tensors [28]. In AdS space, this is not true anymore, but still, each polynomial shift symmetry of level $k$ can be kept separately if the free field $\phi$ has a particular mass depending on $k$ [29, 30]. More precisely, in $\text{AdS}_{d+1}$ a free field $\phi$\(^1\) has a symmetry

$$\phi \rightarrow \phi + c_{\mu_1\ldots\mu_k} X^{\mu_1} \ldots X^{\mu_k}|_{\text{AdS}},$$

(2.6)

where $X^\mu$ are coordinates on an embedding $(d+2)$-dimensional flat spacetime, if the mass of the field equals

$$m_{\phi}^2 = \frac{k(k + d)}{R_{\text{AdS}}^2},$$

(2.7)

with $R_{\text{AdS}}$ the radius of AdS. In a dual CFT, such masses correspond to integer dimensions

$$\Delta_{+} = k + d, \quad \text{or} \quad \Delta_{-} = -k.$$

(2.8)

We conclude that there are indeed polynomial shift symmetries for the moduli and axions (2.1) in DGKT related to the integer dimensions:

$$\Delta_{\phi} = \Delta_{+} = k + 3, \quad k = 3, 7,$$

$$\Delta_{a} = \Delta_{+} = k + 3, \quad k = 2, 8.$$

(2.9)

For the massless axions in (2.2), there are the ordinary constant ($k = 0$) shift symmetries, but for the complex structure moduli with $\Delta = 2$ such a symmetry is absent. A microscopic explanation of these shift symmetries, possibly related to the domain walls discussed in the next section or the discrete symmetries of [31] in the large $N$ limit, would be very interesting.

The non-susy DGKT vacua obtained from the original ones by a change in the sign of the $F_4$-flux still have a full integer spectrum [19], and so the shift symmetries are there as well for all the moduli. There is another class of scale-separated non-susy vacua, described

\(^1\)The interactions in DGKT are $1/N$ suppressed, and so the fields are free in the large flux $N \rightarrow \infty$ limit [16].
in [19], with both irrational and an integer $\Delta = 6$ in the spectrum, so there the shift symmetries are only present for a subset of the moduli.

To check what these symmetries look like on the boundary of AdS, we consider Poincaré coordinates

$$ds^2_{\text{AdS}} = \frac{R^2_{\text{AdS}}}{z^2} \left(-dx_0^2 + \sum_{i=1}^{d-1} dx_i^2 + dz^2 \right),$$

(2.10)

the boundary being at $z = \epsilon, \epsilon \to 0$. Then the polynomial shifts on the boundary reduce to

$$c_{\mu_1...\mu_k} X^{\mu_1} \ldots X^{\mu_k}|_{\text{AdS}} z \to 0 \left(\frac{R_{\text{AdS}}}{z}\right)^k c_{i_1...i_k} X^{i_1} \ldots X^{i_k}|_{\text{boundary}},$$

(2.11)

with $X_i$ coordinates of the flat embedding restricted to the boundary. Considering the near-boundary behaviour of the scalar field

$$\phi \sim \phi_0 z^{\Delta_-} + \phi_1 z^{\Delta_+} = \phi_0 z^{-k} + \phi_1 z^{k+d},$$

(2.12)

we see that the shift acts only on $\phi_0$ as

$$\phi_0 \to \phi_0 + R_{\text{AdS}}^k c_{i_1...i_k} X^{i_1} \ldots X^{i_k}|_{\text{boundary}}.$$ (2.13)

In standard quantization $\phi_0$ is fixed, and this means that the shift symmetry is broken on the boundary [32]. This should be investigated more precisely when more is known about an explicit DGKT CFT dual.

### 3 Large $N$ scalings from D-brane domain walls

Parametric control, and possibly scale separation, can be obtained in AdS flux vacua in the $N \to \infty$ limit, where $N$ is proportional to some unbounded flux. This flux, and also the bounded fluxes needed for moduli stabilization, may be interchanged for brane domain walls interpolating between the AdS vacuum and flat spacetime, as in [24]. Interestingly, an AdS$\times$(torus) geometry may be found in the near-horizon region of this entire brane-system and the dilaton approaches a finite constant when approaching the horizon [24].

In this section, we focus on the branes dual to the unbounded fluxes and explain how one can derive the scalings of the central charge, string coupling, and internal volume for most AdS flux vacua by just looking at the near-horizon geometry of these branes. We first do this for a single stack of domain walls in general flux vacua, and afterwards apply it to some concrete examples including the DGKT and scale-separated AdS$_3$ vacua.

#### 3.1 General flux vacua

If there is one unbounded flux, $F_{8-p} \sim N$, we can change this for $N$ D$p$-branes, wrapped on $(p+2-D)$-cycles, in a 10d flat spacetime consisting of $D$ non-compact directions, the other directions forming a toroidal geometry. These branes can be considered as domain walls in the $D$-dimensional spacetime, with coordinates $(t, x_1, x_2, \ldots x_{D-2}, x)$, and where $x$ will be the direction transverse to the branes. We denote the wrapped internal coordinates by $(y_1, y_2, \ldots y_{p+2-D})$, and the unwrapped ones by $(z_1, z_2, \ldots z_{8-p})$, as shown in Table 2.
Table 2. $N\, D_p$-brane domain walls in $D$ dimensions.

This system is described by [15]

$$ds^2_{10} = f_p^{-1/2} \left[ -dt^2 + dx_1^2 + \cdots + dx_{D-2}^2 \right] + f_p^{3/2} dx_1^2 + f_p^{1/2} dy_idy_j + f_p^{1/2} dz_j dz_j,$$

(3.1)

and the string coupling is

$$g_s = f_p^{3/2},$$

(3.2)

with

$$f_p \sim 1 + \frac{N}{r^p}, \quad r^2 = \sum_i y_i^2 + \sum_j z_j^2,$$

(3.3)

a harmonic function in the transverse coordinates that scales like $f_p \sim N$ in the near-horizon region.

Letting $N \to \infty$, the near-horizon geometry will be of the following schematic form,

$$ds^2_{NH} = \alpha' \left[ N^{1/2} ds^2_{X_D} + N^{-1/2} dy_idy_j + N^{1/2} dz_j dz_j \right],$$

(3.4)

where $X_D$ is the $D$-dimensional spacetime and

$$g_s \sim N^{3/2}.$$

(3.5)

We see that there is a separation of scales between the wrapped internal dimensions and the scale of $X_D$, and we can read off the internal volume in string units:

$$\text{vol}_S \sim (N^{-1/2})^{p+2-D} \cdot (N^{1/2})^{8-D} \cdot l_s^{10-D} = N^{D+6-2p} \cdot l_s^{10-D}.$$

(3.6)

From this, we deduce the D-dimensional Planck length

$$l_{p,D} = (g_s^2 \text{vol}_S^{-1})^{1/(D-2)} l_s = N^{-1/(D-2)} l_s.$$

(3.7)

Hence, the metric in Planck units is

$$ds^2_{NH} = N^{1/2} \left[ N ds^2_{X_D} + dy_idy_j + dz_j dz_j \right] l_{p,D}^2.$$

(3.8)

Then, the AdS radius is

$$R_{\text{AdS}} \sim N^{D-1/2} l_{p,D},$$

(3.9)

and so the central charge will be

$$c \sim (R_{\text{AdS}}/l_{p,D})^{D-2} \sim N^{D-1/2}.$$

(3.10)

Repeating the same calculation for domain walls from NS5-branes, we find

$$g_s \sim N^{1/2}, \quad \text{vol}_S \sim N^{3/2}, \quad c \sim N^{D-1/2},$$

(3.11)
or for F1-strings (only for $D = 3$),

$$g_s \sim N^{-\frac{1}{2}}, \quad \text{vol}_S \sim N^{\frac{D-3}{2}}, \quad c \sim N^{\frac{D-1}{2}}. \quad (3.12)$$

In the examples that we discuss below, there will often be multiple stacks like in Table 2 of D-branes dual to unbounded flux. If these stacks are orthogonally-intersecting, they must satisfy certain composition rules, summarised in [33]. For the $Dp/Dq$-brane intersections that we consider, each pair of these branes must have (0 mod 4) relative transverse coordinates. These are coordinates that are orthogonal to one of the two branes, but not both. Then, we can assign a function $f_{pi}$ to each stack of $Dp$-branes, that only depends on the overall transverse directions. For each of the coordinate directions $\zeta = t, x, y$ or $z$, we then multiply the appropriate powers of these functions as follows,

$$\prod_i f_{pi}^{1/2} \cdot \prod_j f_{qj}^{-1/2} \cdot (d\zeta)^2, \quad (3.13)$$

where the $p_i$-branes are orthogonal, and the $q_j$-branes are parallel to the $\zeta$-direction. With these harmonic superposition rules [34], we obtain the supergravity description of the brane systems. The string coupling will be given by

$$g_s = \prod_i f_{pi}^{3-p_i}, \quad (3.14)$$

where the multiplication is over all branes involved, and we will deduce the central charge and internal volumes from the near-horizon geometries of (3.13).

### 3.2 AdS$_4$ vacua

#### 3.2.1 Scale separated AdS$_4$ vacua in massive IIA string theory (DGKT)

The DGKT [1] potential is given by

$$V = \frac{1}{s^3} \left[ \frac{A_F}{u^3} + \frac{A_{F_0} u^3 s}{s} + \frac{A_{H_S} s}{u^3} - A_{O6} \right], \quad (3.15)$$

where $u^3 = \text{vol}_S$ and $s = e^{-D} = e^{-\phi} \sqrt{\text{vol}_S}$, and the $A$’s are coefficients depending on the values of the fluxes or the orientifold charge, with $A_{O6}^2 = 16 A_{F_0} A_{H_S}$. The Kähler potential equals

$$K = -3 \log u - 4 \log s. \quad (3.16)$$

The conformal dimensions of the dual fields are

$$\Delta_1 = 6, \quad \Delta_2 = 10. \quad (3.17)$$

Imposing the scaling $A_{F_1} \sim N^2$, we find that, at the minimum of the potential

$$V \sim N^{-\frac{3}{2}}, \quad s \sim N^\frac{3}{2}, \quad u \sim N^\frac{1}{2}, \quad (3.18)$$

which means that

$$c \sim N^{9/2}, \quad g_s \sim N^{-3/4}, \quad \text{vol}_S \sim N^{3/2}. \quad (3.19)$$
If the internal manifold is a toroidal orientifold $T^6/\mathbb{Z}_2^3$, $F_{a,i} \sim N_i$ ($i = 1, 2, 3$) flux is turned on along each of the 3 sub-2-tori. We can interchange these 3 fluxes for 3 stacks domain walls consisting of respectively $N_i$ D4-branes wrapped on the different 2-cycles, as shown in Table 3.

As explained in [24], we can also change the other bounded $H_3$- and $F_0$-fluxes for NS5-branes wrapped on 3-cycles and D8-branes on 6-cycles respectively. The resulting near-horizon geometry of this brane set-up will be $\text{AdS}_4 \times T^6$. In the following, we will not explicitly take the presence of these sub-leading branes, dual to bounded fluxes, into account, but just assume they are there to make the near-horizon geometry of the right form and look only at the large $N$ dependence of this geometry.

As $N_i \sim N \to \infty$, using the harmonic superposition rules, we find

$$ds_{NH}^2 = \alpha \left[ N_1^{\frac{1}{2}} N_2^{\frac{1}{2}} N_3^{\frac{1}{2}} ds_{X_4}^2 + N_1^{-\frac{1}{2}} N_2^{\frac{1}{2}} N_3^{\frac{1}{2}} (dy_1^2 + dy_2^2) 
+ N_1^{\frac{1}{2}} N_2^{-\frac{1}{2}} N_3^{\frac{1}{2}} (dy_3^2 + dy_4^2) + N_1^{\frac{1}{2}} N_2^{\frac{1}{2}} N_3^{-\frac{1}{2}} (dy_5^2 + dy_6^2) \right],$$

with

$$g_s \sim N_1^{-\frac{1}{4}} N_2^{-\frac{1}{4}} N_3^{-\frac{1}{4}} \sim N^{-\frac{3}{4}}.$$

The internal volume can be read off,

$$\text{vol}_S \sim N_1^{\frac{1}{2}} N_2^{\frac{1}{2}} N_3^{\frac{1}{2}} \sim N^2,$$

along with the degree of scale separation,

$$\frac{L_{KK}^2}{L_H^2} \sim \max_i(N_i^{-1}) \sim N^{-1}.$$

The 4d Planck scale is given by

$$l_{p,4} = \frac{g_s}{\sqrt{\text{vol}_S}} l_s \sim N_1^{\frac{1}{2}} N_2^{-\frac{1}{2}} N_3^{-\frac{1}{2}} l_s,$$

and so it follows that the central charge is given by

$$c \sim \frac{R_{X_4}^2}{l_{p,4}^2} \sim N_1^3 N_2^3 N_3^3 \sim N^3.$$

We obtain the same scalings as the ones (3.19) from the scalar potential. This match is non-trivial and suggests that the DGKT CFT duals can indeed be found on the D-branes dual to the fluxes. In the next sections we will see that something similar holds for other vacua with integer conformal dimensions.

| $t$ | $x^1$ | $x^2$ | $x$ | $y_1$ | $y_2$ | $y_3$ | $y_4$ | $y_5$ | $y_6$ |

Table 3. D4-brane domain walls in DGKT.
3.2.2 Scale separated AdS$_4$ vacua in massless IIA string theory

We can proceed similarly for scale-separated AdS$_4$ vacua without Romans mass. These are obtained by performing two T-dualities on massive DGKT and then re-scaling fluxes to get a solution under control [4, 33]. The internal manifold will now have curvature becoming a more general SU(3) structure manifold. The flux distribution is anisotropic, with only unbounded flux on 2 out of 3 2-tori in the toroidal case. That is why we now write explicitly $vol_s = u_1u_2u_3$. There is unbounded $F_6$-flux, both bounded $F_2$-flux ($F_{2,1}$) and unbounded $F_2$-flux ($F_{2,2}, F_{2,3}$), a curvature $R$ contribution and again there are O6-planes. The scalar potential is given by

$$V = \frac{1}{s^3} \left[ A_{F_6} \frac{u_2u_3}{su_1} + A_{F_{2,1}} \frac{u_2u_3}{su_1} + A_{F_{2,2}} \frac{u_1u_3}{su_2} + A_{F_{2,3}} \frac{u_1u_2}{su_3} + A_R \frac{su_1}{u_2u_3} - A_{O6} \right], \quad (3.26)$$

with Kähler potential

$$K = - \log u_1u_2u_3 - 4 \log s. \quad (3.27)$$

Conformal dimensions do not change under T-duality:

$$\Delta_{1,2,3} = 6, \quad \Delta_4 = 10. \quad (3.28)$$

Letting $F_6 \sim N$, $F_{2,2} \sim M_1$ and $F_{2,3} \sim M_2$, it follows that

$$c \sim N^{\frac{3}{2}}M_1^{\frac{3}{2}}M_2^{\frac{3}{2}}, \quad g_s \sim N^{\frac{1}{4}}M_1^{-\frac{1}{4}}M_2^{-\frac{1}{4}}, \quad vol_s \sim N^{\frac{3}{2}}M_1^{-\frac{1}{4}}M_2^{-\frac{1}{4}}. \quad (3.29)$$

For $N$ large enough compared to $M_1$ and $M_2$, the coupling will be strong and this solution can be uplifted to M-theory. The first dimension-6 operator can then be interpreted as being dual to the (7d) internal volume.

Now we change the $F_6$-flux for D2-branes, and the unbounded $F_2$-fluxes for D6-branes wrapped on 4-cycles, as in Table 4.

The following near-horizon geometry can be read off:

$$ds_{NH}^2 = \alpha' \left[ N^{\frac{1}{4}}M_1^{\frac{1}{2}}M_2^{\frac{3}{2}}ds_{X_4}^2 + N^{\frac{1}{4}}M_1^{-\frac{1}{2}}M_2^{-\frac{3}{2}}(dy_1^2 + dy_2^2) \right. \quad (3.30)$$

$$+ N^{\frac{1}{2}}M_1^{-\frac{1}{2}}M_2^{\frac{1}{2}}(dy_3^2 + dy_4^2) + N^{\frac{1}{2}}M_1^{\frac{1}{2}}M_2^{-\frac{1}{2}}(dy_5^2 + dy_6^2),$$

with

$$g_s \sim N^{\frac{1}{4}}M_1^{-\frac{1}{4}}M_2^{-\frac{3}{4}}, \quad \frac{L_K^2}{L_H^2} \sim \max_i(M_i^{-1}), \quad (3.31)$$

fully in accordance with the scalings from the scalar potential (3.29).
3.2.3 Other parametric AdS\(_4\) vacua

These large \(N\) scalings from domain walls do not only work out for scale-separated vacua as in the examples above, but also for more general 4d examples with parametric control without scale separation. A simple example is obtained by imposing isotropy \(u_1 = u_2 = u_3\) in the potential of the last section, so that

\[
V = \frac{1}{s^3} \left[ A_{F_6} \frac{1}{su^3} + A_{F_2} \frac{u}{s} + A_{R} \frac{s}{u} - A_{O6} \right],
\]

and then the only unbounded flux will be \(F_6 \sim N\). The conformal dimensions are now

\[
\Delta_1 = 6, \quad \Delta_2 = 11/3.
\]

The scalings are

\[
c \sim N^{\frac{2}{3}}, \quad g_s \sim N^{\frac{1}{3}}, \quad \text{vol}_S \sim N^{\frac{2}{3}},
\]

which coincide with the scalings (3.5), (3.6), (3.10) for one stack of \(N\) D2-branes in 4d.

There is clearly no scale separation,\(^2\) as can be seen from the near-horizon geometry as well,

\[
\alpha' \frac{1}{N} s^2 (ds^2_{\chi_4} + \frac{1}{2} (dy_1^2 + dy_2^2 + dy_3^2 + dy_4^2 + dy_5^2 + dy_6^2))
\]

Reference [35] classifies 2-moduli scalar potentials for asymptotic 4d \(N = 1\) flux vacua. For the AdS vacua they obtain near infinite distance singularities, we observe that

\[
\Delta_1 = 6, \quad \Delta_2 \text{ is rational.}
\]

Moreover, the central charge is always given by

\[
c \sim N^{\frac{k}{2}},
\]

with \(N\) an unbounded flux and \(k\) some positive integer. With (3.10), this suggests that these vacua can be obtained in the near-horizon limit of \(k\) stacks of D-brane domain walls. The string coupling and internal volume scale accordingly. We will report on this in more detail in the future.

3.3 AdS\(_3\) vacua

3.3.1 Scale-separated AdS\(_3\) in massive IIA string theory

The vacua of [25] are scale-separated AdS\(_3\) vacua, from compactification of massive IIA string theory on a G2 holonomy manifold. There are \(F_4\)-, \(H_3\)- and \(F_0\)- fluxes, together with O6-planes, and the scalar potential is:

\[
V = \frac{A_{F_4}}{u^2 s^3} + \frac{A_{F_0} u^2}{s^3} + \frac{A_{H_3}}{u^3 s^2} - \frac{A_{O6} u^4}{s^2},
\]

\(^2\)Hence, the use of a 4d effective potential is strictly speaking not valid. Also, the large \(N\) limit corresponds to strong coupling in this case, which means that these IIA solutions should be uplifted to M-theory to be reliable.
Table 5. D4-brane domain walls for scale-separated AdS$_3$.

|   | $t$ | $x^1$ | $x$ | $y_1$ | $y_2$ | $y_3$ | $y_4$ | $y_5$ | $y_6$ | $y_7$ |
|---|-----|-------|-----|-------|-------|-------|-------|-------|-------|-------|
| $N_1$ D4 | $\otimes$ | $\otimes$ | $\otimes$ | $\otimes$ |       |       |       |       |       |       |
| $N_2$ D4 | $\otimes$ | $\otimes$ |       |       |       |       |       |       |       |       |
| $N_3$ D4 | $\otimes$ | $\otimes$ | $\otimes$ | $\otimes$ |       |       |       |       |       |       |
| $N_4$ D4 | $\otimes$ | $\otimes$ |       |       |       |       |       |       |       |       |
| $N_5$ D4 | $\otimes$ | $\otimes$ |       |       |       |       |       |       |       |       |
| $N_6$ D4 | $\otimes$ | $\otimes$ |       |       |       |       |       |       |       |       |
| $N_7$ D4 | $\otimes$ | $\otimes$ |       |       |       |       |       |       |       |       |

with $A_{Q6}^2 = 12 \cdot A_{f0} \cdot A_{h0}$, and where $u^{7/2} = \text{vol}_S$ and $s = e^{-2\phi} \text{vol}_S$.\[^{3}\] The conformal dimensions are irrational

$$\Delta = 1 + \sqrt{\frac{191 \pm 8\sqrt{277}}{7}}.$$  \hfill (3.39)

With $F_4 \sim N$, we find from (3.38) that

$$c \sim N^4, \quad g_s \sim N^{-3/4}, \quad \text{vol}_S \sim N^{7/4}.$$  \hfill (3.40)

There are such $F_4$-fluxes on seven different 4-cycles, and interchanging them for D4-branes wrapped on the dual 3-cycles, we find the system of Table 5.

There should be further domain walls from NS5-branes and D8-branes, dual to the bounded $H_3$ - and $F_0$-fluxes. If there is indeed an AdS$_3 \times T_7$ geometry in the near-horizon limit of this set of domain walls, the schematic flux dependence should be like

$$ds^2_{NH} = \alpha' \left[ (N_1 \cdot \ldots \cdot N_7)^{1/2} ds^2_{X_3} + (N_1 N_4 N_6)^{-\frac{1}{2}} (N_2 N_3 N_5 N_7)^{\frac{1}{2}} dy_1^2 + \ldots \right]$$

$$= \alpha' \left[ N^{\frac{7}{2}} ds^2_{X_3} + N^{\frac{1}{2}} (dy_1^2 + dy_2^2 + dy_3^2 + dy_4^2 + dy_5^2 + dy_6^2 + dy_7^2) \right],$$

with $N_i = N, i = 1, \ldots 7$. The string coupling (3.5) would be

$$g_s = (N_1 \cdot \ldots \cdot N_7)^{-\frac{1}{4}} = N^{-\frac{7}{4}},$$  \hfill (3.42)

and the internal volume is

$$\text{vol}_S = (N_1 \cdot \ldots \cdot N_7)^{\frac{1}{4}} = N^{\frac{7}{4}}.$$  \hfill (3.43)

Finally, the central charge would be

$$c = N_1 \cdot \ldots \cdot N_7 = N^7.$$  \hfill (3.44)

Remarkably, the scalings of the central charge and the string coupling, derived from the brane system do not match with (3.40). Given that each of the seven internal lengths should scale in the same way with $N$ [25], and taking into account that each pair of stacks of D4-branes should have 0 or 4 relative transverse directions [33], the set-up of Table 5

\[^{3}\]To make contact with the notation in [25]: $u = e^{\frac{2}{7} + 2\beta}$, $s = e^{-\frac{4}{7} + 3\beta}$.\]
is the only possible set-up consisting of orthogonally-intersecting D4-branes. Given the irrational dimensions (3.39) for these vacua, it seems that this simple holographic set-up with orthogonal D-branes, dual to fluxes, only works for vacua with integer conformal dimensions, which go together with the polynomial shift symmetries discussed in section 2.

### 3.3.2 Parametric AdS$_3$ vacua in IIB string theory

To stress that this failure to obtain the scalings from the near-horizon geometry of a simple system of orthogonally-intersecting branes is not generic to asymptotic vacua in 3d, we mention another example: AdS$_3$ vacua from compactification of IIB string theory on G2-structure manifolds (so with curvature $R$) [27] with $F_7$, $F_3$, fluxes and O5-planes and possibly D5-branes. These do not allow scale separation, but the moduli can take parametric values. The scalar potential equals

$$V = \frac{A_{F_7}}{u^2 s^3} + \frac{A_{F_3} u^{1/2}}{s^3} + \frac{A_R}{u s^2} - \frac{A_{O5/D5}}{u^{1/2} s^{3/2}},$$

with $A_{O5/D5}^2 = 16 A_{F_3} \cdot A_R / 3$. The conformal dimensions are now integer and rational

$$\Delta_1 = 4, \quad \Delta_2 = \frac{20}{7}.$$

Choosing $F_7 \sim N$, the scalings

$$c \sim N, \quad g_s \sim N^{1/2}, \quad \text{vol}_S \sim N^{7/4}.$$

from the scalar potential (3.45). These coincide with the scalings (3.5), (3.6), (3.10) for $N$ D1-domain walls in 3d, see Table 6.

### 4 Conclusions

The holographic duals of the DGKT vacua are remarkable, in the sense that their spectrum consists of integer dimensions and that the scaling of the central charge $c \sim N^{9/2}$ is unseen in any well-understood holographic set-up. We have observed, however, that the DGKT scalings are consistent with the large $N$ near-horizon limit of three intersecting stacks of $N$ D4-branes wrapped on 2-cycles. Similarly, the scalings in the scale-separated vacua in massless IIA, obtained after twice T-dualizing the original DGKT vacua [4], are consistent with the near-horizon geometry of one stack of D2-branes and two stacks of D6-branes wrapped on 4-cycles.

More generally, for AdS vacua in $(d + 1)$ dimensions with minimal supersymmetry and an unbounded flux proportional to $N$, and where the conformal dimensions take specific values

$$\Delta_1 = 2d, \quad \Delta_2 \text{ is rational},$$

from the scalar potential (3.45). These coincide with the scalings (3.5), (3.6), (3.10) for $N$ D1-domain walls in 3d, see Table 6.

| $t$ | $x^1$ | $x^2$ | $y^1$ | $y^2$ | $y^3$ | $y^4$ | $y^5$ | $y^6$ | $y^7$ |
|-----|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| $N$ | D1    | $\otimes$ | $\otimes$ |       |       |       |       |       |       |

Table 6. D1-brane domain walls for parametric AdS$_3$. 

---

JHEP05(2023)040
the scalings of the central charge and the moduli deduced from the scalar potential agree with those of a near-horizon geometry of $O(N)$ D-brane domain walls as $N \rightarrow \infty$, whereas this does not seem the case for vacua with irrational dimensions. Hence, for AdS vacua satisfying (4.1), a dual field theory might be found on this set of orthogonally intersecting D-branes dual to the fluxes. Also, the integer dimension $\Delta_1 = 2d$ signals the presence of a level $d$ polynomial shift symmetry for the corresponding field.

The scale-separated AdS$_3$ vacua are unlike their 4-dimensional DGKT counterparts, despite being built from similar ingredients, with irrational dimensions and scalings that cannot be obtained from orthogonal D4-domain walls. Moreover, a massless version ($F_0 \neq 0$) does not exist here [36], preventing an M-theory uplift [37]. Future research will clarify the origin of the failed scalings for the AdS$_3$ vacua and whether they imply any inconsistency.
