Abstract

We apply the harmonic superspace approach for calculating the divergent part of the one-loop effective action of 6D, \( \mathcal{N} = (1,0) \) supersymmetric higher-derivative gauge theory with a dimensionless coupling constant. Our consideration uses the background superfield method allowing to carry out the analysis of the effective action in a manifestly gauge covariant and \( \mathcal{N} = (1,0) \) supersymmetric way. We exploit the regularization by dimensional reduction in which the divergences are absorbed into a renormalization of the coupling constant. Having the expression for the one-loop divergences, we calculate the relevant \( \beta \)-function. Its sign is specified by the overall sign of the classical action which in higher-derivative theories is not fixed \textit{a priori}. The result agrees with the earlier calculations in the component approach. The superfield calculation is simpler and provides possibilities for various generalizations.

1 Introduction

It is well known that field theories with standard kinetic terms and standard interactions are not renormalizable in higher dimensions because of the dimensionful coupling constants and the too slow decrease of propagators at large momenta. Supersymmetry is sometimes capable to improve the ultraviolet behavior in the lowest loops \([1, 2, 8, 4]\), but does not lead to the full renormalizability \([4]\) even in theories with the maximally extended supersymmetry \([5, 6, 7, 8]\).

A way to obtain a higher-dimensional renormalizable theory is to allow the action to include terms with higher derivatives. The study of the higher derivative theories at the classical and quantum levels has a long history that apparently begins with the seminal work by Pais and Uhlenbeck \([9]\). Although the higher-derivative theories suffer from the ghost states in the spectrum, they still attract much attention and are widely used in gravity, cosmology and quantum field theory (see, e.g., \([10, 11, 12, 13, 14]\)). Some of the recent applications, as well as the discussion of ways to evade the problem of ghosts, can be found in Ref. \([15, 16, 17, 18, 19, 20]\) and reviews \([21, 22]\) (and the references therein). So the higher-derivative models are considered to be very interesting and deserving the study from different points of view.

An important example of application of the higher-derivative theories is the regularization by higher-order covariant derivatives \([23, 24]\). This regularization is self-consistent and, for

\textsuperscript{4}stepan@m9com.ru
supersymmetric theories, can be formulated in a manifestly supersymmetric way \cite{25, 26, 27, 28} consistent with the non-renormalization theorems (see, e.g., \cite{29, 30, 31}). When applied for investigating quantum corrections in supersymmetric field theories, the higher-derivative regularization allowed to reveal some interesting features of them (see, e.g., \cite{32, 33} and references therein). This is one more argument why it is useful to study the quantum corrections in higher-derivative supersymmetric theories in various dimensions.

In this paper we study quantum properties of the six-dimensional renormalizable higher-derivative supersymmetric gauge theory proposed in Ref. \cite{34}. This theory describes the following set of the interacting 6D fields: the vector field, the Weyl spinor field, and three real scalar fields, all being in the adjoint representation of the gauge group. The model under consideration involves a dimensionless coupling constant and is formulated in 6D, $\mathcal{N} = (1,0)$ harmonic superspace, which ensures it to be manifestly 6D, $\mathcal{N} = (1,0)$ supersymmetric. The superfield and component forms of the action were earlier given in Ref. \cite{34}. The one-loop divergences and renormalization of the coupling constant in this theory were calculated in Refs. \cite{34, 35} by two different methods based on the component formulations.

The study of various aspects of the four-dimensional supersymmetric quantum field theories (see, e.g., the monographs \cite{29, 30, 31}) provided an evidence that the most attractive and elegant way of investigating their quantum properties is by using superfield methods. The superfield formulation of 6D supersymmetric theories was constructed in Refs. \cite{36, 37, 38} in terms of 6D, $\mathcal{N} = (1,0)$ harmonic superspace which is quite similar to its 4D, $\mathcal{N} = 2$ prototype \cite{39, 40, 41}. The main advantage of such a formulation is the possibility to keep manifest $\mathcal{N} = (1,0)$ supersymmetry at all steps of quantum calculations. In our recent papers \cite{42, 43, 44, 45, 46, 47, 48} we developed the harmonic superfield approach for calculating the lowest off-shell quantum corrections in various 6D, $\mathcal{N} = (1,0)$ and $\mathcal{N} = (1,1)$ supersymmetric theories. In the present paper we apply this superfield technique for studying the one-loop effective action in 6D, $\mathcal{N} = (1,0)$ higher-derivative gauge theory of Ref. \cite{34}.

The paper is organized as follows. In Sect. 2 we collect the basic notions of 6D, $\mathcal{N} = (1,0)$ harmonic superspace and the formulation of the model under consideration within its framework. Sect. 3 presents the manifestly supersymmetric and gauge covariant quantization of this theory and the construction of the corresponding effective action. In Sect. 4 we compute the one-loop divergences by a direct calculation of the harmonic supergraphs and find the $\beta$-function. The results and some further problems are summarized in Conclusion. The technical details of the calculation are contained in Appendices A and B.

2 Harmonic superspace formulation of 6D, $\mathcal{N} = (1,0)$ higher-derivative SYM theory

The harmonic superspace technique is most convenient for formulating theories with 6D, $\mathcal{N} = (1,0)$ supersymmetry as it suggests the manifestly supersymmetric and gauge invariant scheme of their quantization.

In our notation the coordinates of 6D Minkowski space and the $\mathcal{N} = (1,0)$ Grassmann coordinates are denoted by $x^M$ and $\theta^a$, with $M = 0, \ldots, 5$, $a = 1, \ldots, 4$, and $i = 1, 2$. The coordinates $(x^M, \theta^a, u^\pm_i)$ of the harmonic superspace include in addition the harmonic variables $u^\pm_i$ which obey the constraints $u^+i u^-_i = 1$, $u^-_i \equiv (u^+_i)^*$. Having these coordinates at hand, one can construct the harmonic derivatives

$$D^{++} = u^{+i} \frac{\partial}{\partial u^+_i}; \quad D^{--} = u^{-i} \frac{\partial}{\partial u^-_i}; \quad D^0 = u^{+i} \frac{\partial}{\partial u^+_i} - u^{-i} \frac{\partial}{\partial u^-_i},$$

(2.1)
which generate an $SU(2)$ algebra. The harmonic superspace contains an analytic subspace closed under the $6D, \mathcal{N} = (1, 0)$ supersymmetry transformations. It is parametrized by the coordinates

$$x^M_A = x^M + \frac{i}{2} \theta^a \gamma^M \theta^+; \quad \theta^\pm a = u^\pm_i \theta^{ai},$$

(2.2)

where $\gamma^M$ are $6D \gamma$-matrices.

We also introduce the harmonic spinor covariant derivatives

$$D^+_a = u^+_i D^i_a; \quad D^-_a = u^-_i D^i_a,$$

(2.3)

the only non-zero anticommutation relation among which being $\{D^+_a, D^-_b\} = i (\gamma^M)_{ab} \partial_M$. Due to the anticommutativity of the derivatives $D^+_a$ any product of four such derivatives (defined with respect to the same harmonic variable $u$) is reduced to the expression

$$(D^+_a)^4 = -\frac{1}{24} \varepsilon^{abcd} D^+_a D^+_b D^+_c D^+_d.$$  

(2.4)

In this paper we adopt the following convention for the superspace integration measures needed for constructing the $\mathcal{N} = (1, 0)$ invariant actions:

$$\int d\zeta^{(-4)} \equiv \int d^6 x d^4 \theta^+; \quad \int d^{1+4} z \equiv \int d^6 x d^8 \theta = \int d^6 x d^4 \theta^+ (D^+_a)^4.$$  

(2.5)

In the harmonic superspace formulation the gauge field is carried by the superfield $V^{++}(z, u) = V^{++} t^A$ which obeys the analyticity condition

$$D^+_a V^{++} = 0$$

(2.6)

and is real with respect to a generalized conjugation denoted by a tilde, $\tilde{V}^{++} = V^{++}$. In this paper we use the Hermitian generators $t^A$ which are normalized by the conditions $\text{tr}(t^A t^B) = \delta^{AB}/2$. From the gauge superfield $V^{++}$ one can construct a non-analytic superfield

$$V^{--}(z, u) \equiv \sum_{n=1}^{\infty} (-i)^{n+1} \int du_1 du_2 \ldots du_n \frac{V^{++}(z, u_1) V^{++}(z, u_2) \ldots V^{++}(z, u_n)}{(u^+_1 u^-_1)(u^+_2 u^-_2) \ldots (u^+_n u^-_n)},$$

(2.7)

and, further, the harmonic gauge superfield strength

$$F^{++} \equiv (D^+_a)^4 V^{--}.$$  

(2.8)

It is evidently analytic. Moreover, it satisfies the off-shell condition

$$\nabla^{++} F^{++} \equiv D^{++} F^{++} + i [V^{++}, F^{++}] = 0,$$

(2.9)

which is a consequence of the harmonic flatness condition

$$D^{++} V^{--} - D^{--} V^{++} + i [V^{++}, V^{--}] = 0.$$  

(2.10)

The latter can be considered as a definition of $V^{--}$.

The gauge transformations in the harmonic superspace are parametrized by the real (with respect to the tilde-conjugation) analytic superfield $\lambda = \lambda^A t^A$:

$$V^{\pm \pm} \to e^{i \lambda} V^{\pm \pm} e^{-i \lambda} - i e^{i \lambda} D^{\pm \pm} e^{-i \lambda}, \quad F^{++} \to e^{i \lambda} F^{++} e^{-i \lambda}.$$  

(2.11)
The $6D, \mathcal{N} = (1, 0)$ supersymmetric generalization of the usual $6D$ Yang–Mills theory in the harmonic superspace formulation is given by the action \[ S_{\text{SYM}} = \frac{1}{f_0} \sum_{n=2}^{\infty} \left( -\frac{i}{n} \right)^n \text{tr} \int d^{14}z \, du_1 \ldots du_n \frac{V^{++}(z, u_1) \ldots V^{++}(z, u_n)}{(u_1^+ u_2^+) \ldots (u_n^+ u_1^+)}, \] (2.12) with the coupling constant $f_0$ having the dimension of the inverse mass. It is clear that this theory is not renormalizable by power counting. A theory with a dimensionless coupling constant $g_0$ should evidently involve higher derivatives in its action. Such a theory has been constructed in the harmonic superspace in [34]. It is described by the following manifestly gauge invariant action

\[ S = \pm \frac{1}{2g_0^2} \text{tr} \int d\zeta (-4)^2 du (F^{++})^2 = \pm \frac{1}{4g_0^2} \int d\zeta (-4)^2 du (F^{++A})^2. \] (2.13)

The component form of this action was also worked out in [34]. The aim of our paper is to investigate the one-loop divergences for the theory with the action (2.13).

The sign of the action (2.13) deserves some comments. In conventional field theory models without higher derivatives the overall sign is fixed by the requirement that the energy is positive. In the higher-derivative theories the energy is not positively defined in general. This means, that there are no actual reasons to fix an overall sign of the action in such theories. This is why we cannot fix the sign of the action (2.13)\footnote{This point was also noted in [35].}. Note that in Ref. [34] there was chosen the sign minus since it gives rise to the correct sign in front of the component kinetic term of the triplet of scalar fields entering the gauge $\mathcal{N} = (1, 0)$ multiplet (the former auxiliary fields). However, this does not imply the positivity of energy for all component fields which involve higher-derivative ghosts for any sign.

3 Background field quantization in harmonic superspace

The harmonic superspace technique makes it possible to construct the manifestly $\mathcal{N} = (1, 0)$ supersymmetric quantization procedure. It is also convenient to use the background superfield method [50, 51, 52] which provides a manifestly gauge invariant effective action. In $6D, \mathcal{N} = (1, 0)$ harmonic superspace it is formulated similarly to the $4D, \mathcal{N} = 2$ case treated in [53, 54]. In particular, the background-quantum splitting is linear,

\[ V^{++} = V^{++} + v^{++}, \] (3.1)

where $V^{++}$ and $v^{++}$ are the background and quantum gauge superfields, respectively. After the substitution of (3.1) in the action (2.13) the gauge invariance (2.11) amounts to the two types of transformations. The background gauge invariance

\[ V^{++} \to e^{i\lambda} V^{++} e^{-i\lambda} - ie^{i\lambda} D^{++} e^{-i\lambda}, \quad v^{++} \to e^{i\lambda} v^{++} e^{-i\lambda} \] (3.2)

remains a manifest symmetry of the effective action, while the quantum gauge invariance

\[ V^{++} \to V^{++}, \quad v^{++} \to e^{i\lambda} (v^{++} + V^{++}) e^{-i\lambda} - V^{++} - ie^{i\lambda} D^{++} e^{-i\lambda} \] (3.3)

is broken by the gauge-fixing procedure down to the invariance under the BRST transformations. It is assumed that the gauge-fixing term should be chosen invariant under the transformations (3.2). The harmonic superspace analog of the $\xi$-gauge is then given by the action
\[ S_{gf} = \mp \frac{1}{2 g_0^2} \text{tr} \int d^{14} z \, du_1 \, du_2 \, \frac{(u_1^2 - u_2^2)}{(u_1^2 u_2^2)^3} e^{ib_1} e^{-ib_2} (\nabla_2^{++} v_2^{++} + \nabla_2^{++} v_2^{++}) e^{ib_2} e^{-ib_1} \big( \nabla_1^{++} v_1^{++} \big), \]  

where the operator

\[ \bigotimes \equiv \frac{1}{2} (D^+)^4 (\nabla^-)^2 \]  

is reduced to the covariant analog of the d’Alambertian operator, when acting on the analytic superfields. The background covariant derivatives are defined as

\[ \nabla^{++} = D^{++} + i V^{++}; \quad \nabla^{--} = D^{--} + i V^{--}. \]  

Evidently, if they act on a superfield in the adjoint representation (e.g., on \( v^{++} \)), the gauge superfields should be expanded over the generators of the adjoint representation, so that

\[ \nabla^{\pm\pm} v^{++} = D^{\pm\pm} v^{++} + i [V^{\pm\pm}, v^{++}]. \]  

The background bridge superfield \( b \) in Eq. (3.4) is related to the background superfields \( V^{++} \) and \( V^{--} \) (constructed out of \( V^{++} \) by the equation similar to (2.7)) via the relations

\[ V^{++} = -i e^{ib} D^{++} e^{-ib}; \quad V^{--} = -i e^{ib} D^{--} e^{-ib}. \]  

The subscripts 1 and 2 in Eq. (3.4) refer to the harmonic variables \( u_1 \) or \( u_2 \) present in \( S_{gf} \). Similar notation will be used below.

The action for the Faddeev–Popov ghosts corresponding to the gauge-fixing action (3.4) is obtained in the standard way (see, e.g., [53]) and is given by

\[ S_{FP} = \text{tr} \int d\zeta (-4) du \, b \nabla^{++} \left( \nabla^{++} c + i [v^{++}, c] \right), \]  

where the anticommuting analytic superfields \( b \) and \( c \) stand for the Faddeev–Popov antighosts and ghosts, respectively. However, the presence of the operator \( \bigotimes \) in Eq. (3.4) change the form of the Nielsen–Kallosh determinant. Namely, in the case under consideration it can be written in the form

\[ \Delta_{NK} = \text{Det}^{-1/2} (\nabla^{++})^2 \text{Det} \bigotimes = \int D\varphi \, D\chi^{(+4)} \, D\sigma \, \exp \left( i S_{NK} \right), \]  

where the set of Nielsen–Kallosh ghosts involves the commuting analytic superfield \( \varphi \) together with the Grassmann-odd analytic superfields \( \chi^{(+4)} \) and \( \sigma \), all being in the adjoint representation of the gauge group. The action for these ghosts reads

\[ S_{NK} = \text{tr} \int d\zeta (-4) du \left( -\frac{1}{2} (\nabla^{++} \varphi)^2 + \chi^{(+4)} \bigotimes \sigma \right). \]  

Then the generating functional for the considered theory can finally be written in the form

\[ Z[\text{Sources}, V^{++}] = \int Dv^{++} Db \, Dc \, D\varphi \, D\chi^{(+4)} \, D\sigma \, \exp \left\{ i \left( S + S_{gf} + S_{FP} + S_{NK} + S_{sources} \right) \right\}. \]  

\(^6\)In principle, in the framework of the background field method we could use any appropriate gauge preserving the background gauge invariance. However, it is technically convenient to choose the action \( S_{gf} \) to be of the same degree in derivatives as the classical action.
The source term is defined as

$$S_{\text{sources}} = \int d\zeta (-4) du J^{++A} v^{++A} + \ldots,$$

(3.13)

where dots denote terms corresponding to various ghost superfields. The effective action \( \Gamma[\text{Fields}, V^{++}] \) is defined as the Legendre transform of the generating functional for the connected Green functions \( W \equiv -i \ln Z \). Setting all quantum fields equal to zero, we obtain the manifestly gauge invariant action \( \Gamma[V^{++}] \equiv \Gamma[\text{Fields} \rightarrow 0, V^{++}] \).

Like in the case of standard 6D, \( \mathcal{N} = (1, 0) \) SYM theory [43, 44], there are two ways to calculate divergent terms in this action. One of them is based on the superfield proper-time technique and preserves manifest gauge invariance at all steps. Another goes through the direct calculation of the relevant Feynman supergraphs with invoking gauge invariance at the final stage. Here we employ the second method, leaving the first one for the future study.

4 Calculation of the divergent supergraphs

The one-loop contribution to the two-point Green function of the background gauge superfield for the considered model is given by the supergraphs depicted on Fig. 1. We will calculate it in the minimal gauge \( \xi = 1 \), where \( \xi \) is the renormalized gauge-fixing parameter. The external wavy lines in the supergraphs on Fig. 1 represent the background gauge superfield \( V^{++} \) (or to the background bridge \( b \)). The wavy internal lines correspond to the propagators of the quantum gauge superfield \( v^{++} \). In the Feynman gauge this propagator has the simplest form and is given by the expression

$$\left. - \frac{\delta^2 Z_0}{\delta J^{++A}_1 \delta J^{++B}_2} \right|_{J^{++}=0} = \pm 2i g_0^2 (D^+_2)^4 \delta^{14}(z_1 - z_2) \delta^{(2, -2)}(u_1, u_2),$$

(4.1)

where

$$\delta^{14}(z_1 - z_2) \equiv \delta^6(x_1 - x_2) \delta^8(\theta_1 - \theta_2)$$

(4.2)

and \( Z_0 \) denotes the generating functional of the free theory. The dashed lines denote propagators of the Faddeev–Popov and Nielsen–Kallosh ghosts. All ghost contributions have already been calculated earlier [43, 44]. Actually, the ghost part of the generating functional for the theory under consideration and for the theory (2.12) differ only in the expression

$$\left( \int D\chi^{(+4)} D\sigma \exp \left\{ i \text{tr} \int d\zeta (-4) du \chi^{(+4)} \square \sigma \right\} \right)^{1/2}.$$

(4.3)

However, according to [44] this expression cannot produce divergences. This implies that the total ghost contribution (which include both Faddeev–Popov and Nielsen–Kallosh parts and can
be found by calculating the supergraphs (3) and (4) in Fig. 1 coincides with the one for the theory (2.12) and, according to [44], is equal to

$$\Delta \Gamma^{(1)}_{\infty}^{\text{ghost}} = \frac{C_2}{3 \varepsilon (4 \pi)^3} \text{tr} \int d\zeta (\xi) du (F^{++})^2,$$

(4.4)

where it is assumed that the regularization by dimensional reduction is used, with $\varepsilon \equiv 6 - D$. The constant $C_2$ is defined by the equation $f^{ABC} f^{BCD} = C_2 \delta^{AB}$, where the structure constants $f^{ABC}$ are given by the commutator of generators, $[t^A, t^B] = i f^{ABC} t^C$.

Thus, it remains to calculate only the one-loop divergences produced by the supergraphs containing a loop of the gauge quantum superfield. These divergences are completely determined by the part of the total action quadratic in the quantum gauge superfield (which does not contain other quantum superfields). Obviously, such terms are present only in the classical action (2.13) and the gauge-fixing action (3.4). In Appendix A we demonstrate that, in the Feynman gauge $\xi_0 = 1$,

$$S^{(2)} + S_{gf} = \pm \frac{1}{2g_0^2} \text{tr} \int d\zeta (\xi) du v^{++} \Box v^{++} + \frac{i}{2g_0^2} \text{tr} \int d^{14} z du_1 du_2 \frac{1}{(u_1^+ u_2^+)^2} e^{ib_1} e^{-ib_2} v^{++}_1 + e^{ib_2} e^{-ib_1} [F^{++}_1, \nabla^{--}_1 v^{++}_1].$$

(4.5)

Starting from this expression we calculate the one-loop divergences coming from the supergraphs which contain a loop of the quantum gauge superfield (see Appendix B). Namely, from the expression (4.5) we find the vertices in the supergraphs depicted on Fig. 1. Next, we calculate the first two supergraphs in Fig. 1 and obtain the corresponding contribution to the divergent part of the two-point Green function of the background gauge superfield. Finally, taking into account the background gauge invariance of the effective action, we obtain the general result for all one-loop divergences coming from the supergraphs with a loop of the quantum gauge superfield inside. The result is given by the expression

$$\Delta \Gamma^{(1)}_{\infty}^{\text{gauge}} = -\frac{4C_2}{3 \varepsilon (4 \pi)^3} \text{tr} \int d\zeta (\xi) du (F^{++})^2.$$

(4.6)

Summing up Eqs. (4.5) and (4.6), we obtain that the divergent part of the one-loop effective action for the theory (2.13) regularized by the dimensional reduction takes the form

$$\Delta \Gamma^{(1)}_{\infty} = \Delta \Gamma^{(1)}_{\infty}^{\text{gauge}} + \Delta \Gamma^{(1)}_{\infty}^{\text{ghost}} = -\frac{11C_2}{3 \varepsilon (4 \pi)^3} \text{tr} \int d\zeta (\xi) du (F^{++})^2.$$

(4.7)

This result exactly agrees with the ones obtained in Refs. [34, 35] starting from the component formulation of the theory in the Wess–Zumino gauge.

Adding the expression (4.7) to the classical action (2.13) we can find quantum corrections to the coupling constant $g_0$,

$$\Gamma - S_{gf} = \left( \pm \frac{1}{2g_0^2} + \frac{11C_2}{3 \varepsilon (4 \pi)^3} \right) \text{tr} \int d\zeta (\xi) du (F^{++})^2 \quad + \text{finite one-loop contributions} \quad + \text{higher order corrections.}$$

(4.8)

From this expression we see that the renormalized coupling constant $g$ is related to $g_0$ as

$$\frac{1}{g^2} = \frac{1}{g_0^2} \mp \frac{22C_2}{3 \varepsilon (4 \pi)^3} + \text{higher orders},$$

(4.9)

When calculating the one-loop divergences, there is no difference between choices $\xi_0 = 1$ and $\xi = 1$. 

7
which exactly agrees with the relation obtained in (the revised version of) Ref. [34] and in Ref. [35]. It is more convenient to rewrite it in terms of $\alpha \equiv g^2 / 4\pi$,

$$\frac{1}{\alpha} = \frac{1}{\alpha_0} \mp \frac{22C_2}{3\varepsilon(4\pi)^2} + \text{higher orders.} \quad (4.10)$$

This relation implies that the one-loop $\beta$-function is given by the expression

$$\beta(\alpha) = \mp \frac{11\alpha^2C_2}{24\pi^2} + \text{higher orders.} \quad (4.11)$$

Thus, the lower sign corresponds to the Landau zero, while the upper sign corresponds to the asymptotic freedom. If one takes into account the difference in the notations, the former choice was used in Ref. [34], while the calculation of Ref. [35] corresponds to the latter case.

5 Conclusion

In this paper we have considered the higher-derivative $6D, \mathcal{N} = (1, 0)$ supersymmetric Yang-Mills theory in the harmonic superspace formulation. The theory was quantized within the background superfield method which allows to preserve the manifest gauge invariance and $6D, \mathcal{N} = (1, 0)$ supersymmetry at all stages of the quantum calculations. Using the supergraph technique and the regularization by dimensional reduction we have calculated the one-loop divergences of the quantum effective action. The calculations were organized as follows. The divergences were firstly found to the lowest order with respect to the background gauge superfield. Then, using the manifest gauge invariance, the full result for the divergent part of the one-loop effective action was restored. It was shown that the divergences can be absorbed into the renormalization of the dimensionless coupling constant $g_0$. The corresponding $\beta$-function was computed and its sign was shown to be determined by the sign of the initial “microscopic” action.

It is natural to expect that the theory will remain renormalizable after adding to the action (2.13) the action of $6D, \mathcal{N} = (1, 0)$ gauge theory without higher derivatives involving a dimensionful coupling constant $f_0$. It would be interesting to study the renormalization properties of such a theory involving two coupling constants $g_0$ and $f_0$. Another interesting problem is the construction of the $6D, \mathcal{N} = (1, 1)$ higher-derivative supersymmetric gauge theory and the study of its renormalization properties. For this purpose one should extend the theory considered here by higher-derivative couplings with the hypermultiplet in the adjoint representation (e.g., along the line of Ref. [55]) and try to ensure the hidden $\mathcal{N} = (0, 1)$ supersymmetry in such an extended $6D$ system. These problems will be addressed elsewhere.

---

*As was already mentioned, an alternative to this calculation is the computational procedure preserving the manifest gauge invariance at all steps and based on the superfield proper-time technique [43]. We plan to consider this approach in the forthcoming paper.*
Appendix

A The second variation of the classical action

For calculating the one-loop divergences we need to single out that part of the action which is quadratic in the quantum gauge superfields. As is evident from Eq. (3.1), to this end one should calculate the second variation of the action, then make the replacement

\[ \delta V^{++} \rightarrow v^{++}; \quad V^{++} \rightarrow V^{++}, \]  

(A.1)

and finally multiply the result by 1/2.

The first variation of the action (2.13) is given by the expression

\[ \delta S = \pm \frac{1}{g_0^2} \text{tr} \int d^{2} \delta \zeta (\gamma^{-1}) d \mu^{++} \delta F^{++} = \pm \frac{1}{g_0^2} \text{tr} \int d^{14} z d u F^{++} \delta V^{--}. \]  

(A.2)

To obtain the variation \( \delta V^{--} \), note that, as a consequence of Eq. (2.10), it should satisfy the relation

\[ \nabla^{++} \delta V^{--} = \nabla^{--} \delta V^{++}, \]  

(A.3)

where the covariant derivatives are defined as

\[ \nabla^{++} \equiv D^{++} + iV^{++}, \quad \nabla^{--} \equiv D^{--} + iV^{--}. \]  

(A.4)

Note that, in contrast to Eqs. (3.6), these equation contain the superfields \( V^{±±} \) (instead of \( V^{±±} \)). The solution of Eq. (A.3) satisfies the equation

\[ \delta V^{--} = \frac{1}{2} (\nabla^{--})^2 \delta V^{++} - \frac{1}{2} \nabla^{++} \nabla^{--} \delta V^{--}. \]  

(A.5)

Substituting this expression into (A.2) and using (2.14), the first variation of the action can be presented in the form

\[ \delta S = \pm \frac{1}{g_0^2} \text{tr} \int d^{14} z d u F^{++} (\nabla^{--})^2 \delta V^{--}. \]  

(A.6)

Next, we calculate the second variation

\[ \delta^2 S = \delta (\delta S) = \pm \frac{1}{g_0^2} \text{tr} \int d^{14} z d u \left( \delta F^{++} (\nabla^{--})^2 \delta V^{++} + iF^{++} \left[ \delta V^{--}, \nabla^{--} \delta V^{++} \right] ight) \]

\[ + iF^{++} \nabla^{--} \left[ \delta V^{--}, \delta V^{++} \right]. \]  

(A.7)

Substituting \( \delta F^{++} = (D^+)^4 \delta V^{--} \) into this expression, after some algebra we obtain

\[ \delta^2 S = \pm \frac{1}{g_0^2} \text{tr} \int d^{14} z d u \left( \delta V^{--} \nabla^{--} \delta V^{++} \right. \]

\[ - \frac{i}{2} \delta V^{--} \left[ F^{++}, \nabla^{--} \delta V^{++} \right] + \frac{i}{2} \delta V^{--} \left[ \nabla^{--} F^{++}, \delta V^{++} \right]. \]  

(A.8)

where

\[ \nabla^{--} \equiv \frac{1}{2} (D^+)^4 (\nabla^{--})^2. \]  

(A.9)
To find the variation $\delta V^{--}$ we introduce the (non-analytic) bridge superfield $b$ related to $V^{\pm \pm}$ by the relations similar to (3.8),

$$V^{++} = -ie^{ib}D^{++}e^{-ib}; \quad V^{--} = -ie^{ib}D^{--}e^{-ib}.$$  \hfill (A.10)

Then, taking into account that $\nabla^{\pm \pm} = e^{ib}D^{\pm \pm}e^{-ib}$, the solution of Eq. (A.3) can be written as

$$\delta V^{--}_{1} = \int du_{2} \frac{1}{(u_{1}^{+}u_{2}^{+})^{2}} e^{ib_{1}}e^{-ib_{2}}\delta V^{;++}_{2}e^{ib_{2}}e^{-ib_{1}},$$  \hfill (A.11)

where the subscripts refer to the corresponding harmonic variables.

Substituting the expression (A.11) into Eq. (A.8) we rewrite the second variation of the action (2.13) as

$$\delta^{2}S = \pm \frac{1}{g_{0}^{2}} \text{tr} \int d^{14}z \, du_{1} \, du_{2} \frac{1}{(u_{1}^{+}u_{2}^{+})^{2}} e^{ib_{1}}e^{-ib_{2}}\partial_{v} \delta V^{;++}_{2}e^{ib_{2}}e^{-ib_{1}}$$

$$\times \left( \Box_{1} \, \delta V^{;++}_{1} - i\frac{1}{2} F^{[++]} + \nabla^{--}\delta V^{;++}_{1} + i\frac{1}{2} \left[ \nabla^{--}F^{[++]}, \delta V^{;++}_{1} \right] \right).$$  \hfill (A.12)

Making in this expression the replacement (A.1) and multiplying the result by $1/2$ we obtain that part of the action (2.13) which is quadratic in the quantum gauge superfields,

$$S^{(2)} = \pm \frac{1}{2g_{0}^{2}} \text{tr} \int d^{14}z \, du_{1} \, du_{2} \frac{1}{(u_{1}^{+}u_{2}^{+})^{2}} e^{ib_{1}}e^{-ib_{2}}v^{;++}_{2}e^{ib_{2}}e^{-ib_{1}}$$

$$\times \left( \Box_{1} v^{;++}_{1} - i\frac{1}{2} F^{[++]} + \nabla^{--}v^{;++}_{1} + i\frac{1}{2} \left[ \nabla^{--}F^{[++]}, v^{;++}_{1} \right] \right).$$  \hfill (A.13)

To obtain the analogous part of the total action, we should add the gauge-fixing action (3.4) to this expression. Using the identity

$$\left[ \Box_{1}, \nabla^{++} \right] v^{++} = \frac{1}{2}(D^{+})^{4} \left[ (\nabla^{--})^{2}, \nabla^{++} \right] v^{++} = -\frac{1}{2}(D^{+})^{4} \left( D^{0} \nabla^{--} + \nabla^{--}D^{0} \right) v^{++}$$

$$= -(D^{+})^{4} \nabla^{--}v^{++} = -i[F^{++}, v^{++}]$$  \hfill (A.14)

after integrating by parts with respect to the harmonic derivatives the gauge-fixing term can be rewritten as

$$S_{gf} = \pm \frac{1}{2g_{0}^{2}e} \, \text{tr} \, d^{14}z \, du_{1} \, du_{2} \, e^{ib_{1}}e^{-ib_{2}}v^{;++}_{2}e^{ib_{2}}e^{-ib_{1}} \left\{ D^{+}D^{+} + \frac{(u_{1}^{-}u_{2}^{-})}{(u_{1}^{+}u_{2}^{+})^{3}} \Box_{1} v^{;++}_{1} \right\}$$

$$+ iD_{2}^{++} \left( \frac{(u_{1}^{-}u_{2}^{-})}{(u_{1}^{+}u_{2}^{+})^{3}} \right) [F^{[++]}, v^{;++}_{1}] \right\}. \hfill (A.15)$$

Then, with the help of the identities

$$D^{++}_{1} + D^{++}_{2} \left( \frac{(u_{1}^{-}u_{2}^{-})}{(u_{1}^{+}u_{2}^{+})^{3}} \right) = \frac{1}{(u_{1}^{+}u_{2}^{+})^{2}} - \frac{1}{2} (D_{1}^{--})^{2} \delta(2, -2)(u_{1}, u_{2}),$$  \hfill (A.16)

$$D^{++}_{2} \left( \frac{(u_{1}^{-}u_{2}^{-})}{(u_{1}^{+}u_{2}^{+})^{3}} \right) = \frac{(u_{1}^{-}u_{2}^{-})}{(u_{1}^{+}u_{2}^{+})^{3}} = -\frac{1}{2} D_{1}^{--} \left( \frac{1}{(u_{1}^{+}u_{2}^{+})^{2}} \right)$$  \hfill (A.17)
it is convenient to rearrange the expression (A.15) to the form

\[ S_{gf} = \pm \frac{1}{2g_0^2} \text{tr} \int d\zeta (-4) \, du \, v^{++} \, \Box^2 v^{++} + \frac{1}{2g_0^2} \text{tr} \int d^{14}z \, du_1 \, du_2 \, \frac{1}{(u_{1}^{+} u_{2}^{+})^2} \times e^{i(b_1 e^{-i(b_2 u_1^{-})} + e^{i(b_2 e^{-i(b_1 u_1^{-})})}} \left\{ \Box_1 v_1^{++} + \frac{i}{2} \, \nabla_1 \cdot \mathbf{F}_1^{++}, v_1^{++} \right\}. \] (A.18)

The quadratic in the quantum gauge superfield part of the total action is obtained as a sum of the expressions (A.13) and (A.15),

\[ S^{(2)} + S_{gf} = \pm \frac{1}{2g_0^2} \text{tr} \int d\zeta (-4) \, du \, v^{++} \, \Box^2 v^{++} + \frac{1}{2g_0^2} \text{tr} \int d^{14}z \, du_1 \, du_2 \, \frac{1}{(u_{1}^{+} u_{2}^{+})^2} e^{i(b_1 e^{-i(b_2 u_1^{-})} + e^{i(b_2 e^{-i(b_1 u_1^{-})})}} \left\{ (1 - \frac{1}{\xi_0}) \Box_1 v_1^{++} + \frac{i}{2} \left( 1 - \frac{1}{\xi_0} \right) \left[ \mathbf{F}_1^{++} \right] - \frac{i}{2} \left( 1 + \frac{1}{\xi_0} \right) \left[ \mathbf{F}_1^{++}, \nabla_1 \cdot v_1^{++} \right] \right\}. \] (A.19)

This expression is drastically simplified in the Feynman gauge \( \xi_0 = 1 \). In this gauge Eq. (A.19) is reduced to the expression (4.5).

**B  Divergences of the supergraphs with a gauge loop**

Let us calculate the one-loop divergences coming from the first two supergraphs presented in Fig. 1. Both these supergraphs contain a loop of the quantum gauge superfield, so that the vertices can be found from the expression (4.5). In particular, the triple vertex present in the supergraph (1) can be written as

\[ V^{linear}_{++} \equiv \int d^{14}z \, du \, v^{++} \, A \left[ V_{linear}^{--+} D^{--} v^{++} + D^{--} \left( V_{linear}^{--+} v^{++} \right) \right] \]

\[ \pm \frac{1}{4g_0^2} f^{ABC} \int d^{14}z \, du \, v^{++} \, A \left[ V_{linear}^{--+} D^{--} v^{++} + D^{--} \left( V_{linear}^{--+} v^{++} \right) \right] \]

where the subscript “linear” means that it is enough to consider only the part linear in the background gauge superfield \( V^{++} \).

\[ V^{linear}_{++} \equiv \int d^{14}z \, du \, v^{++} \, A \left[ V_{linear}^{--+} D^{--} v^{++} + D^{--} \left( V_{linear}^{--+} v^{++} \right) \right] \]

\[ \pm \frac{1}{4g_0^2} f^{ABC} \int d^{14}z \, du \, v^{++} \, A \left[ V_{linear}^{--+} D^{--} v^{++} + D^{--} \left( V_{linear}^{--+} v^{++} \right) \right] \]

We see that the vertex (B.1) can naturally be divided into the two parts, \( \text{Ver}_1 \) and \( \text{Ver}_2 \). The first one is composed of the terms which include \( V_{linear}^{--} \), while the second one contains the term with \( F^{++} \). Therefore, the supergraph (1) in Fig. 1 splits into three subgraphs, namely, \( \text{Ver}_1 - \text{Ver}_1, \text{Ver}_2 - \text{Ver}_2, \) and \( \text{Ver}_1 - \text{Ver}_2 \). The subgraph containing two vertices \( \text{Ver}_1 \) is very similar to an analogous supergraph calculated in Ref. [44] and vanishes due to the presence of the factors

\[ (D_i^{--})^4 (u_1^{+} u_2^{+})^4 \bigg|_{u_1 = u_2} = 0 \quad \text{or} \quad D_i^{--} (u_1^{+} u_2^{+})^4 \bigg|_{u_1 = u_2} = 0. \] (B.3)

The subgraph \( \text{Ver}_2 - \text{Ver}_2 \) is proportional to

\[ \int \frac{d^6k}{(2\pi)^6} \frac{1}{k^4 (k + p)^4} \] (B.4)
and is, therefore, finite. This implies that this subgraph does not contribute to the divergent part of the one-loop effective action and can be omitted.

Thus, we see that the only non-trivial contribution of the supergraph (1) to the one-loop divergences can appear from the \textup{(}logarithmically divergent\textup{)} subgraph $\text{Ver}_1 - \text{Ver}_2$. Applying Feynman rules, we find that the considered contribution to the effective action is given by the expression

$$\text{Ver}_1 - \text{Ver}_2 = \frac{iC_2}{4} \int d^{14} z_1 d^{14} z_2 d\theta d\theta' d\phi \frac{1}{(u_2^+ u_3^+)^2} V_{\text{linear}}^{A} (z_1, u_1) F_{\text{linear}}^{++A} (z_2, u_2)$$

\begin{align*}
&\times \left\{ D_2^- \left[ \frac{1}{i\partial^4} (D_3^+)^4 \delta^{(14)} (z_1 - z_2) \delta^{(2,2)} (u_1, u_2) \right] D_1^- \left[ \frac{1}{i\partial^4} (D_3^+)^4 \delta^{(14)} (z_1 - z_2) \delta^{(2,2)} (u_1, u_3) \right] \\
&- D_1^- D_2^- \left[ \frac{1}{i\partial^4} (D_3^+)^4 \delta^{(14)} (z_1 - z_2) \delta^{(2,2)} (u_1, u_2) \right] \frac{1}{i\partial^4} (D_3^+)^4 \delta^{(14)} (z_1 - z_2) \delta^{(2,2)} (u_1, u_3) \\
&+ D_2^- \left[ \frac{1}{i\partial^4} (D_3^+)^4 \delta^{(14)} (z_1 - z_2) \delta^{(2,2)} (u_1, u_2) \right] D_1^- \left[ \frac{1}{i\partial^4} (D_3^+)^4 \delta^{(14)} (z_1 - z_2) \delta^{(2,2)} (u_1, u_3) \right] \\
&- D_1^- D_2^- \left[ \frac{1}{i\partial^4} (D_3^+)^4 \delta^{(14)} (z_1 - z_2) \delta^{(2,2)} (u_1, u_2) \right] \frac{1}{i\partial^4} (D_3^+)^4 \delta^{(14)} (z_1 - z_2) \delta^{(2,2)} (u_1, u_3) \right\}. \tag{B.5}
\end{align*}

Note that, without a loss of generality, we can assume that all spinor derivatives act on the point $z_1$.

The $\delta$-functions $\delta^{14}(z_1 - z_2)$ include $\delta^8(\theta_1 - \theta_2)$, and the product of two Grassmannian $\delta$-functions does not vanish only in the situation when at least 8 spinor covariant derivatives act on them. Taking into account this property and using the identity

$$\delta^8(\theta_1 - \theta_2) (D_3^+)^4 (D_3^+)^4 \delta^8(\theta_1 - \theta_2) = (u_1^+ u_2^+)^4 \delta^8(\theta_1 - \theta_2) \tag{B.6}$$

we can do one of the integrals over $d^8\theta$. Then, in the momentum representation, Eq. (B.5) can be brought in the form

\begin{align*}
&\frac{iC_2}{2} \int d^8 \theta \, d\theta_1 \, d\theta_2 \, d\theta_3 \int \frac{d^6 p}{(2\pi)^6} \frac{d^6 k}{(2\pi)^6} \frac{1}{k^4 (k + p)^2} V_{\text{linear}}^{A} (-p, \theta, u_1) F_{\text{linear}}^{++A} (p, \theta, u_2) \frac{1}{(u_2^+ u_3^+)^2} \\
&\times \left\{ D_2^- \left[ (u_2^+ u_3^+) \delta^{(2,2)} (u_1, u_2) \right] D_1^- \delta^{(2,2)} (u_1, u_3) \\
&- D_1^- D_2^- \left[ (u_2^+ u_3^+) \delta^{(2,2)} (u_1, u_2) \right] \delta^{(2,2)} (u_1, u_3) \right\}. \tag{B.7}
\end{align*}

After integrating by parts with respect to the derivative $D_1^-$ in the last term, this expression can be rewritten as

\begin{align*}
&\frac{iC_2}{2} \int d^8 \theta \, d\theta_1 \, d\theta_2 \, d\theta_3 \int \frac{d^6 p}{(2\pi)^6} \frac{d^6 k}{(2\pi)^6} \frac{1}{k^4 (k + p)^2} F_{\text{linear}}^{++A} (p, \theta, u_2) \left\{ \frac{2}{(u_2^+ u_3^+)^2} \\
&\times V_{\text{linear}}^{A} (-p, \theta, u_1) D_2^- \left[ (u_2^+ u_3^+) \delta^{(2,2)} (u_1, u_2) \right] D_1^- \delta^{(2,2)} (u_1, u_3) + (u_2^+ u_3^+)^2 \\
&\times D_1^- V_{\text{linear}}^{A} (-p, \theta, u_1) D_2^- \delta^{(2,2)} (u_1, u_2) \delta^{(2,2)} (u_1, u_3) \right\}, \tag{B.8}
\end{align*}

where we took into account that

\begin{equation}
(u_2^+ u_3^+) \delta^{(2,2)} (u_1, u_2) \delta^{(2,2)} (u_1, u_3) \to 0. \tag{B.9}
\end{equation}
Once again, integrating by parts with respect to the derivative $D_2^-$ and doing the integral over $du_1$ with the help of $\delta^{(2,-2)}(u_1,u_2)$, we obtain

$$
\text{Ver}_1 - \text{Ver}_2 = \frac{iC_2}{2} \int d^8 \theta \, du_2 \, du_3 \int \frac{d^6 p}{(2\pi)^6} \frac{d^6 k}{(2\pi)^6} \frac{1}{k^4(k+p)^2} \times \left\{ 4V^{-A}_{\text{linear}}(-p,\theta,u_2) F^{++A}_{\text{linear}}(p,\theta,u_2) (u_2^+ u_3^+) (u_2^+ u_3^+) D_2^- - \frac{\delta^{(2,-2)}}{u_2, u_3} \right\}
$$

Two last terms in this expression evidently vanish because they contain

$$(u_2^+ u_3^+) \delta^{(2,-2)}(u_2, u_3) \to 0.$$

Integrating by parts with respect to the derivative $D_2^-$ in the remaining terms we see that the only expression which does not contain the vanishing product (B.11) is

$$
-2iC_2 \int d^8 \theta \, du_2 \, du_3 \int \frac{d^6 p}{(2\pi)^6} \frac{d^6 k}{(2\pi)^6} \frac{1}{k^4(k+p)^2} \times V^{-A}_{\text{linear}}(-p,\theta,u_2) F^{++A}_{\text{linear}}(p,\theta,u_2) (u_2^+ u_3^+) (u_2^+ u_3^+) \delta^{(2,-2)}(u_2, u_3). \tag{B.12}
$$

After calculating the harmonic integrals, this expression takes the form

$$
-2iC_2 \int d^8 \theta \, du \int \frac{d^6 p}{(2\pi)^6} \frac{d^6 k}{(2\pi)^6} \frac{1}{k^4(k+p)^2} V^{-A}_{\text{linear}}(-p,\theta,u) F^{++A}_{\text{linear}}(p,\theta,u). \tag{B.13}
$$

The momentum integral in this expression is calculated in the Euclidean space after the standard Wick rotation with the help of dimensional reduction. Clearly, we are interested in its divergent part only,

$$
\int \frac{d^6 k}{(2\pi)^6} \frac{1}{k^4(k+p)^2} \to -i \int \frac{d^D K}{(2\pi)^D} \frac{1}{K^6} + \text{finite terms} = -\frac{i}{\varepsilon(4\pi)^3} + \text{finite terms}, \tag{B.14}
$$

where the capital letter $K$ denotes the Euclidean loop momentum.

Thus, in the coordinate representation we obtain the following divergent contribution coming from the supergraph (1) in Fig. [1]

$$
\left[ \text{diagram (1)} \right]_\infty = -\frac{2C_2}{\varepsilon(4\pi)^3} \int d^4 z \, du \, \left( V^{--A}_{\text{linear}} F^{++A}_{\text{linear}} \right)^2 = -\frac{4C_2}{\varepsilon(4\pi)^3} \text{tr} \int d\zeta(-4) du \left( F^{++A}_{\text{linear}} \right)^2. \tag{B.15}
$$

Now, let us calculate the contribution of the tadpole supergraph (2) in Fig. [1]. The relevant vertex is also obtained from the expression (B.13) and is composed out of the terms quadratic in the background gauge superfield $V^{++}$ and in the background bridge $b$. 

13
\[ \pm \frac{1}{2 g_0^2} \text{tr} \int d^{14} z \, d u \{ i \partial^2 v^{++} [V_{\text{quadratic}}, D^{--} v^{++}] + i \partial^2 v^{++} D^{--} [V_{\text{quadratic}}, v^{++}] \]
\[ - \partial^2 v^{++} [V^{--} [V^{--}, v^{++}]] - \frac{1}{4} \left( [V^{--}, D^{--} v^{++}] + D^{--} [V^{--}, v^{++}] \right) (D^+)^4 \]
\[ \times \left( [V^{--}, D^{--} v^{++}] + D^{--} [V^{--}, v^{++}] \right) \} \pm \frac{1}{2 g_0^2} \text{tr} \int d^{14} z \, d u_1 \, d u_2 \left( \frac{u_1^+ u_2^+}{2} \right)^2 \]
\[ \times \left\{ [b_1 - b_2, v_2^{++}] \left[ F^{++}_{\text{linear}, 1}, D^{--} v_1^{++} \right] - iv_2^{++} \left[ F^{++}_{\text{quadratic}, 1}, D^{--} v_1^{++} \right] \right\}, \tag{B.16} \]

where \( V^{--} \) and \( F^{++} \) are those parts of \( V^{--} \) and \( F^{++} \) which are quadratic in \( V^{++} \). Constructing the corresponding expression for the contribution of the supergraph (2), we see that all terms in it vanish either because the number of spinor derivatives acting on the anticommuting \( \delta \)-function at the coincident arguments is less than 8 (for all terms without \( (D^+)^4 \) in Eq. (B.16)), or because of the presence of \( (u_1^+ u_2^+) \bigg|_{u_1 = u_2} = 0 \) (for the terms containing \( (D^+)^4 \)). Therefore, the supergraph (2) in Fig. 1 does not contribute to the divergent part of the one-loop effective action.

Thus, the one-loop divergences coming from the supergraphs (1) and (2) in Fig. 1 are given by Eq. (B.15). However, the gauge superfield \( V^{++} \) is dimensionless, so that the one-loop divergences are also present in supergraphs with an arbitrary number of the external gauge legs. The general result for the divergent part of the one-loop effective action can be restored by resorting to the manifest gauge invariance of the effective action \( \Gamma[V^{++}] \). The gauge invariant expression which in the lowest approximation yields Eq. (B.15) is evidently given just by Eq. (4.6).
