A dual colorimetric probe for rapid environmental monitoring of Hg$^{2+}$ and As$^{3+}$ using gold nanoparticles functionalized with D-penicillamine

Su-Jin Yoon,$^{a,c}$ Yun-Sik Nam,$^d$ Yeonhee Lee, $^b$ In Hwan Oh$^a$ and Kang-Bong Lee $^{d,ac}$

A highly sensitive and selective colorimetric assay for the dual detection of Hg$^{2+}$ and As$^{3+}$ using gold nanoparticles (AuNPs) conjugated with D-penicillamine (DPL) was developed. When Hg$^{2+}$ and As$^{3+}$ ions coordinate with AuNP-bound DPLs, the interparticle distance decreases, inducing aggregation; this results in a significant color change from wine red to dark midnight blue. The Hg$^{4f}$ and As$^{3d}$ signals in the X-ray photoelectron spectra of Hg$^{2+}$ (As$^{3+}$)-DPL-AuNPs presented binding energies indicative of Hg$^{2+}$–N(O) and As$^{3+}$–N(O) bonds, and the molecular fragment observed in time-of-flight secondary ion mass spectra confirmed that Hg$^{2+}$ and As$^{3+}$ coordinated with two oxygen and two nitrogen atoms in DPL. The detection of Hg$^{2+}$ and As$^{3+}$ can be accomplished by observing the color change with the naked eye or by photometric methods, and this was optimized to provide optimal probe sensitivity. The assay method can be applied for environmental monitoring by first selectively quantifying Hg$^{2+}$ in water samples at pH 6, then estimating the As$^{3+}$ concentration at pH 4.5. The efficiency of the DPL-AuNP probe was evaluated for the sequential quantification of Hg$^{2+}$ and As$^{3+}$ in tap, pond, waste, and river water samples, and absorbance ratios ($A_{730}/A_{525}$) were correlated with Hg$^{2+}$ and As$^{3+}$ concentrations in the linear range of 0–1.4 μM. The limits of detection in water samples were found to be 0.5 and 0.7 nM for Hg$^{2+}$ and As$^{3+}$, respectively. This novel probe can be utilized for the dual determination of Hg$^{2+}$ and As$^{3+}$, even in the presence of interfering substances in environmental samples.

1 Introduction

Mercury ions are ubiquitous in the environment as both inorganic and organic compounds, since reagents containing mercury are widely used in industry, agriculture, and medicine.$^{5,6}$ Hg$^{2+}$ ions are nonessential and toxic to humans. They accumulate mainly in the kidneys, and give rise to vomiting and diarrhea followed by hypovolemic shock, oliguric renal failure, and possibly death.$^{4,5}$ Thus, the US Environmental Protection Agency and the World Health Organization (WHO) have established maximum permissible levels of Hg in drinking water of 10 and 30 nM, respectively.$^{5,6}$

Arsenic is a toxic substance with acute and chronic effects; long-term exposure to arsenic can cause various cancers and other serious diseases.$^7$ The concentration of arsenic in the environment can be elevated by various anthropogenic activities and natural processes.$^8$ Arsenic contamination in drinking water has been prevalent worldwide, and as many as 140 million people may have been exposed to drinking water with arsenic levels higher than the WHO guideline of 0.13 μM.$^8$

Several analytical techniques including atomic absorption spectroscopy,$^9$ atomic fluorescence spectroscopy,$^{10}$ inductively coupled plasma-atomic emission spectrometry,$^{11}$ and inductively coupled plasma-mass spectrometry$^{12,13}$ have been utilized for the consecutive determination of Hg$^{2+}$ and As$^{3+}$ ions. However, these methods generally require complicated sample pretreatment processes, skillful technicians, and sophisticated instrument facilities. Therefore, the development of a low-cost and easy-to-use analytical method for the selective detection of these two toxic ions would be highly desirable for analytical chemists.

Nanoparticle (NP)-based colorimetric assays for the selective detection of Hg$^{2+}$ ions using silver nanoparticles (AgNPs),$^{14,15}$ silver nanoprism,$^{16}$ gold nanoparticles (AuNPs),$^{17–19}$ gold nanostars,$^{20}$ SiO$_2$ core-shell NPs,$^{21}$ and carbon nanoparticles (CNPs)$^{22}$ have recently been reported, and assays for the sensing of As$^{3+}$ ions using AgNPs,$^{12,23}$ AuNPs,$^{25,26}$ and copper nanoparticles (CuNPs)$^{27}$ were documented.
Although a method for the simultaneous sensing of Hg$^{2+}$ and As$^{3+}$ ions has been previously reported, it crudely involved two AuNP probes functionalized with different ligands.\textsuperscript{28} Herein, we report the development of a single sensing probe for monitoring both Hg$^{2+}$ and As$^{3+}$ ions using AuNPs functionalized with \textalpha-penicillamine (DPL) as a dual-response sensor. This AuNP probe is especially promising for the consecutive analysis of Hg$^{2+}$ and As$^{3+}$ ions using the naked eye or UV-Vis spectroscopy due to the high extinction coefficients of the species involved and their interparticle-distance-dependent optical properties.

DPL is a medication primarily used for the treatment of Wilson’s disease. It is also used for patients with kidney stones who have high urine cystine levels or rheumatoid arthritis and in the treatment of poisoning with various heavy metals. Its amine and carboxyl groups provide active sites that can form strong interactions with chelated species, and the oxygen (or nitrogen) atoms of DPL could be expected to specifically coordinate with mercury and arsenic cations as a function of pH.

**Fig. 3** (A) XPS spectra of the AuNPs, DPL-AuNPs, Hg$^{2+}$-DPL-AuNPs, and As$^{3+}$-DPL-AuNPs. (B) High-resolution Hg4f spectra of the Hg$^{2+}$-DPL-AuNPs. The deconvoluted signals at 100.7 eV and 104.5 eV were attributed to Hg$^{2+}$–O bonds, and that at 102.7 eV was attributed to Hg$^{2+}$–N bonding. (C) High-resolution As3d spectra of the As$^{3+}$-DPL-AuNPs. The deconvoluted signals at 44.5 eV and 45.2 eV were attributed to As$^{3+}$–O bonds, and the deconvoluted signal at 43.5 eV was attributed to As$^{3+}$–N bonding.
The present study demonstrates that DPL-AuNPs aggregate in the presence of mercury and/or arsenic ions as a function of pH, selectively inducing a definite color change in the AuNPs in the presence of other ions. Dispersed AuNPs and those aggregated upon the addition of Hg$^{2+}$ or As$^{3+}$ ions were characterized using UV-Vis spectroscopy, high-resolution transmission electron microscopy (HR-TEM), and dynamic light scattering (DLS). The Hg$^{2+}$ ion binding sites on the surface of the DPL-AuNPs were elucidated using Fourier-transform infrared spectroscopy (FTIR), X-ray photoelectron spectroscopy (XPS) and time-of-flight secondary ion mass spectrometry (TOF-SIMS). The interference effects of other metal ions and anions were tested. Furthermore, the developed DPL-AuNP assay for the consecutive detection of Hg$^{2+}$ and As$^{3+}$ ions was optimized in terms of pH, temperature, and salt concentration. The present assay method is straightforward and cost efficient and allows for the on-site dual detection of Hg$^{2+}$ and As$^{3+}$ ions in a wide range of practical situations.

Although colorimetric AuNP sensors are extremely useful and simple, they are ordinarily employed only in single-target assays. Advances in material sciences and analytical techniques have enabled the development of novel multicolor AuNP sensors capable of detecting multiple-target from a single sample. This study demonstrated that a probe capable of sequentially detecting both Hg$^{2+}$ and As$^{3+}$ ions in various environmental matrices is more efficient and profitable than single-target nanoparticle probes. Although challenges still exist in the development of efficient and practical colorimetric AuNP probes, the scope for further advancements and practical applications of colorimetric strategies in environmental monitoring is undeniable.

2 Materials and methods

2.1 Materials

Hydrogen tetrachloroaurate(III) trihydrate (HAuCl$_4$·3H$_2$O), trisodium citrate (TSC), DPL, mercury(II) chloride, and arsenic trichloride were sourced from Sigma-Aldrich (St. Louis, MO, USA). The salts of the metal ions (Li$^+$, Na$^+$, K$^+$, Ag$^+$, Ba$^{2+}$, Ca$^{2+}$, Cd$^{2+}$, Co$^{2+}$, Cu$^{2+}$, Mn$^{2+}$, Mg$^{2+}$, Ni$^{2+}$, Pb$^{2+}$, Sn$^{2+}$, Zn$^{2+}$, Al$^{3+}$, Ga$^{3+}$, Fe$^{3+}$, Ti$^{3+}$, Ge$^{4+}$, and Cr$^{6+}$) and anions (NO$_2^-$, NO$_3^-$, PO$_4^{3-}$, SO$_4^{2-}$, F$^-$, CI$^-$, Br$^-$, and I$^-$) were purchased from Accu Standard (New Haven, CT, USA). NaCl, HCl, and NaOH were purchased from Samchun Chemical (Gyeong gi-Do, Republic of Korea). Distilled water was obtained using a Milli-Q water purification system (Millipore, Bedford, MA, USA). Reagents were used as received without further purification. To test the utility of the method, tap and pond water samples were collected from the Korea Institute of Science and Technology (KIST) campus.

2.2 Preparation of AuNPs and DPL-AuNPs

The AuNPs were prepared by simple reduction of HAuCl$_4$ with TSC as reported elsewhere. A specific size of AuNPs (~20 nm) was prepared using a 3.0 mM TSC concentration. DPL-AuNPs were then prepared via a ligand-exchange reaction between DPL and citrate-stabilized AuNPs. A 0.3 mM solution of HAuCl$_4$ in water (100 mL) was prepared in a round-bottom flask. The solution was heated under continuous stirring in a reflux condenser. Upon boiling, a 38.8 mM TSC solution was slowly injected. The color of the solution changed from pale yellow to wine red. The solution was heated at reflux for 30 min.

Fig. 4 Mass peaks corresponding to (A) NH$_2$CHCO$_2$Hg$^{2+}$ (m/z: 274.97), (NH$_2$O)$_2$Hg$^{2+}$ (m/z: 265.97), (CH$_2$NH$_2$)$_2$Hg$^{2+}$ (m/z: 259.97), and CH$_3$NH$_2$CHCO$_2$Hg$^{2+}$ (m/z: 274.97) and (B) NH$_2$CHCO$_2$As$^{3+}$ (m/z: 147.92), (NH$_2$O)$_2$As$^{3+}$ (m/z: 138.92), (CH$_2$NH$_2$)$_2$As$^{3+}$ (m/z: 132.92), CH$_3$NH$_2$CHCO$_2$As$^{3+}$ (m/z: 162.92) fragments in the TOF-SIMS spectra of the DPL-AuNPs (black), Hg$^{2+}$-DPL-AuNPs (red) and As$^{3+}$-DPL-AuNPs (blue). These molecular fragments were expected based on Hg$^{2+}$-DPL-AuNPs and As$^{3+}$-DPL-AuNPs structural elements.
Subsequently, the solution was cooled to room temperature and stored in a refrigerator at 4 °C. The self-aggregation of the DPL-AuNPs was tested; no color change was observed in the DPL-AuNP solution formed by the addition of 4 mM DPL, which indicated that the DPL-AuNP did not self-aggregate. The free DPL molecules in solution were removed by centrifugation at 6000 rpm for 10 min, yielding the DPL-AuNPs.

2.3 Sample preparation for dual determination of Hg²⁺ and As³⁺ using DPL-AuNPs

Real water samples were collected from the laboratory tap and a pond at KIST. The tap water samples were used without further purification and spiked with known concentrations of Hg²⁺ and As³⁺ ions. The pond and waste water samples were filtered through 0.45 and 0.2 μm membranes and then spiked with...
standard solutions of Hg²⁺ and As³⁺ ions. To determine the Hg²⁺ and As³⁺ concentrations using the DPL-AuNPs, a range of Hg²⁺ and As³⁺ concentrations were prepared (0.0–2.0 μM). Each Hg²⁺ and As³⁺ solution was added to 1.8 mL of the DPL-AuNP solution, and the resulting mixtures were allowed to react for 2.0 min. Subsequently, the changes in their absorbance were monitored using UV-Vis. All experiments were carried out at 25 °C. Determination of Hg²⁺ (or As³⁺) was accomplished by plotting the ratio A₇30/A₅25 vs. the concentration of Hg²⁺ (or As³⁺).

2.4 Instrumentation
UV-Vis absorption spectra were measured in the 300–800 nm range using polystyrene cells with a 1 mm path length and an S-3100 spectrophotometer S-3100 (Sinco, Seoul, Republic of Korea). Solution pH was measured using an HI 2210 pH meter (Hanna instruments, Woonsocket, RI, USA). FTIR spectra were obtained using an FTIR spectrometer (Thermo Mattson, Infinity Gold FTIR, Waltham, MA, USA) equipped with a mercury cadmium telluride detector and zinc selenide crystal ATR. DLS and zeta potential measurements were conducted using a Zetasizer instrument (Malvern Instruments Ltd, Worcestershire, UK). Images of the AuNPs, DPL-AuNPs, aggregated Hg²⁺-DPL-AuNPs, and aggregated As³⁺-DPL-AuNPs were obtained via transmission electron microscopy (TEM, Titan, FEI™, Oregon, USA) and used to determine their diameters. XPS was performed using a PHI 5000 VersaProbe (Ulvac-PHI, Kanagawa, Japan) with a background pressure of 2.0 × 10⁻⁷Pa, monochromated Al Kx source (1486.6 eV) and anode (24.5 W, 15 kV). Mass spectra were measured using time of flight-secondary ion mass spectrometry (TOF-SIMS, IONTOF, Münster, Germany).

3 Results and discussion
3.1 Characterization of AuNPs, DPL-AuNPs, and their complexes with Hg²⁺ and As³⁺
AuNPs with a specific size of ~20 nm were prepared via the simple reduction of HAuCl₄ with 3.0 mM TSC. The strong localized surface plasmon resonance peak of these AuNPs appears at ~525 nm in their UV-Vis spectra, resulting in the wine-red color of the corresponding solutions, and the size of AuNPs has affected its surface plasmon absorption maxima. We obtained the IR spectra of DPL, DPL-AuNPs, Hg²⁺-DPL-AuNPs, and As³⁺-DPL-AuNPs. As expected, the IR spectrum of DPL shows a characteristic S–H stretching band at 2523 cm⁻¹, which disappears in the IR spectrum of the DPL-AuNPs (Fig. 1A and B). This indicates that the DPL must be conjugated with the AuNPs through its sulfur atom. The free DPL molecules in solution were removed by centrifugation at 6000 rpm for 10 min to yield the DPL-AuNPs. Additionally, the COO⁻ asymmetric stretching band observed at 1586 cm⁻¹ in the DPL and DPL-AuNP spectra shifted to become an CO stretching band at 1710 cm⁻¹ after conjugation of DPL-AuNP with Hg²⁺ (or As³⁺), which indicates that Hg²⁺ (or As³⁺) must be coordinated with an oxygen atom of the COO⁻ group in DPL (Fig. 1).

The UV-Vis absorption spectra of the AuNPs, DPL-AuNPs, Hg²⁺-DPL-AuNPs, and As³⁺-DPL-AuNPs solutions are shown in Fig. 2A. UV-Vis spectroscopic analysis of the DPL-AuNPs was performed daily over one month to evaluate the stability of the colloidal suspensions at room temperature. The spectra remained unchanged over this period (not shown). Thus, AuNPs functionalized with DPL were stable for a month in terms of dispersion state, morphology, size, and surface chemistry.

Functionalized AuNPs can serve as localized surface plasmon resonance (LSPR) probes owing to their sensitive spectral response to local changes in the environment surrounding the nanoparticle surface. The absorbance spectra of DPL-AuNPs changed dramatically with respect to both peak position and intensity as a result of aggregation induced by the addition of Hg²⁺ or As³⁺. Upon the addition of Hg²⁺ (or As³⁺) ions, the intense absorption band of the DPL-AuNPs at 525 nm gradually shifted to 730 nm, and this LSPR shift resulted in the appearance and increase in intensity of a new absorbance band (Fig. 2A). In aggregated DPL-AuNPs, the conduction electrons near the surfaces become delocalized and are shared amongst neighboring particles. As a result, the surface plasmon...
resonance shifts to a lower energy, causing a change in absorption to longer wavelengths. In the current study, the sizes of the DPL-AuNPs and Hg$^{2+}$-DPL-AuNPs (or As$^{3+}$-DPL-AuNPs) were distributed around 20 and 90 nm, respectively, according to Zetasizer measurements and TEM images (Fig. 2B). The color of the DPL-AuNPs is similar to those of previously reported label-free AuNPs, but a distinct color change from wine red to dark midnight blue occurred upon the addition of Hg$^{2+}$ or As$^{3+}$ ions. When Hg$^{2+}$ and As$^{3+}$ ions coordinate with AuNP-bound DPL, the interparticle distance decreases, inducing aggregation; this is accompanied by a significant color change of the probe/analyte mixture. In addition, this selective aggregation of DPL-AuNPs could be harnessed to remove toxic Hg$^{2+}$ and As$^{3+}$ ions from drinking water.

3.2 Binding sites of Hg$^{2+}$ (or As$^{3+}$) ions to DPL-AuNP

XPS spectra of the AuNPs, DPL-AuNPs, Hg$^{2+}$-DPL-AuNPs, and As$^{3+}$-DPL-AuNPs were measured to investigate the sites the binding of the Hg$^{2+}$ (or As$^{3+}$) ions to the DPL-AuNPs (Fig. 3). The high-resolution Hg4f signals of the Hg$^{2+}$-DPL-AuNPs at 100.7 eV and 104.5 eV were attributed to Hg$^{2+}$–O bonds, and the Hg4f signal at 102.7 eV was attributed to the binding energy of an Hg$^{2+}$–N bond. The high-resolution As3d signal of the As$^{3+}$-DPL-AuNPs at 44.5 eV was attributed to As$^{3+}$–O bonds, while the As3d signal at 43.5 eV was ascribed to the binding energy of an As$^{3+}$–N bond.

The TOF-SIMS spectra of the DPL-AuNPs, Hg$^{2+}$-DPL-AuNPs, and As$^{3+}$-DPL-AuNPs provide additional information regarding the sites of the binding of Hg$^{2+}$ and As$^{3+}$ to the DPL-AuNPs (Fig. 4). These mass spectra reveal signals corresponding to the molecular fragments NH$_2$CHCO$_2$Hg$^{2+}$ (m/z: 274.97), (NH$_2$O)$_2$Hg$^{2+}$ (m/z: 265.97), (CHNH$_2$)$_2$Hg$^{2+}$ (m/z: 259.97), and CH$_3$NH$_2$CHCO$_2$Hg$^{2+}$ (m/z: 274.97) for the Hg$^{2+}$-DPL-AuNPs. Additionally, NH$_2$CHCO$_2$As$^{3+}$ (m/z: 147.92), (NH$_2$O)$_2$As$^{3+}$ (m/z: 138.92), (CHNH$_2$)$_2$As$^{3+}$ (m/z: 132.92), CH$_3$NH$_2$CHCO$_2$As$^{3+}$ (m/z: 162.92) fragments were observed in the mass spectrum of the As$^{3+}$-DPL-AuNPs. These molecular fragments do not appear for the DPL-AuNPs, confirming that Hg$^{2+}$ and As$^{3+}$ must be coordinated with the two oxygen atoms of the carboxyl group and two nitrogen atoms of the amine group in DPL.

3.3 Selectivity of DPL-AuNPs for Hg$^{2+}$ and As$^{3+}$ ions and related interference effects

The selectivity of the DPL-AuNP probe was tested by comparing the $A_{730}/A_{525}$ ratio of the Hg$^{2+}$ and As$^{3+}$ ions with those of various metal cations (Li$^+$, Na$^+$, K$^+$, Ag$^+$, Ba$^{2+}$, Ca$^{2+}$, Cd$^{2+}$, Co$^{2+}$, Cu$^{2+}$, Mn$^{2+}$, Mg$^{2+}$, Ni$^{2+}$, Pb$^{2+}$, Sn$^{2+}$, Zn$^{2+}$, Al$^{3+}$, Fe$^{3+}$, Ga$^{3+}$, Ti$^{3+}$, Ge$^{4+}$, and Cr$^{6+}$) and anions (NO$_2^-$, NO$_3^-$, PO$_4^{3-}$, SO$_4^{2-}$, F$^-$, Cl$^-$, Br$^-$, and I$^-$) under the same conditions. The AuNPs conjugated with DPL responded selectively to Hg$^{2+}$ or As$^{3+}$ ions, as indicated by the profound color change, UV-Vis spectral change, and dramatic increase in $A_{730}/A_{525}$ (Fig. 5A and B). Thus, we successfully achieved the aggregation of DPL-AuNPs using Hg$^{2+}$ or As$^{3+}$ ions. The decrease in the $A_{525}$ value, and the development of a new absorbance band at 730 nm were attributed to the coupled plasmon absorbance of the AuNPs due to closer contact with other AuNPs as a result of aggregation. The $A_{730}/A_{525}$ values induced by Hg$^{2+}$ or As$^{3+}$ ions were at least six times greater than those observed in the presence of other metal cations and anions, indicating a distinct interaction between the DPL-AuNPs and Hg$^{2+}$ (or As$^{3+}$) ions. In other words, Hg$^{2+}$ (or As$^{3+}$) ions must exhibited highly preferential affinity for the oxygen and nitrogen atoms of DPL compared to that of all the metal
ions tested, and the proposed geometrical shape of the resulting complex is displayed in Scheme 1.

To test for interference of the other ions in the selectivity of the probe toward Hg$^{2+}$ or As$^{3+}$, the changes in the spectra of the sensors with $1 \ \mu$M Hg$^{2+}$ or $1 \ \mu$M As$^{3+}$ were evaluated in the presence of 0.1 mM of the other ions. The other ions did not interfere with the determination of Hg$^{2+}$ or As$^{3+}$, even when the concentrations were much higher than that of Hg$^{2+}$ or As$^{3+}$ (Fig. 5C). Therefore, the proposed method could be utilized for the selective determination of Hg$^{2+}$ or As$^{3+}$, even in the presence of high concentrations of possible interfering substances.

### 3.4 Optimum conditions for the DPL-AuNP probe

To optimize the sensitivity of the DPL-AuNP probe for Hg$^{2+}$ and As$^{3+}$, different pH values, temperatures, salt concentrations, and reaction time were tested. The excellent selectivity of the DPL-AuNPs for both Hg$^{2+}$ and As$^{3+}$ ions was effective only within a specific pH range. That is, the Hg$^{2+}$ and As$^{3+}$ ions did not cause any color change at pH values higher than 8 and 5, respectively (Fig. 6). The absorbance ratios ($A_{730}/A_{525}$) changed as a function of the pH, and were highest at pH 6 and pH 4.5 for Hg$^{2+}$ and As$^{3+}$, respectively (Fig. 6). Therefore, the Hg$^{2+}$ ions can be determined selectively and optimally at pH 6, after which the concentration of the As$^{3+}$ ions can be measured by subtracting the Hg$^{2+}$ ion concentration observed at pH 6 from the total concentration of Hg$^{2+}$ and As$^{3+}$ ions measured at pH 4.5. The optimum pH values of the DPL-AuNP probe for Hg$^{2+}$ and As$^{3+}$ sensing seemed to be related to the $pK_a$ values of its functional groups ($pK_a$ of carboxyl group: $\sim$1.8; $pK_a$ of amino group: $\sim$7.8) and the conformation of DPL. Thus, Hg$^{2+}$ and As$^{3+}$ are optimally coordinated to the oxygen atoms of the carboxyl group and the nitrogen atoms of the amino group in DPL at pH 6 and 4.5, respectively, which provides the highest probe sensitivity.

The sensitivity of the DPL-AuNP probe towards Hg$^{2+}$ and As$^{3+}$ ions was examined as a function of temperature in the range 10–70 °C, and its sensitivity was found to be optimum at 30 °C (Fig. 7A). Furthermore, the sensitivity of the DPL-AuNP probe was monitored as a function of the NaCl concentration, and found to be greatest at a NaCl concentration of 250 mM (Fig. 7B).

The optimum concentration of DPL to be conjugated with the AuNPs was investigated using a 1.0 mM Hg$^{2+}$ (or As$^{3+}$) solution, and the absorbance ratios ($A_{730}/A_{525}$) in the resulting UV-Vis spectra revealed that optimal concentration of DPL was $\sim$33 μM (data not shown).

### 3.5 Quantitation of Hg$^{2+}$ and As$^{3+}$ using the DPL-AuNP assay method

The changes in the color, UV-Vis spectra, and TEM images of the DPL-AuNP probe upon the addition of Hg$^{2+}$ and As$^{3+}$ ions were monitored. The color of the DPL-AuNPs changed gradually from wine red to midnight blue as the concentration of

![Fig. 7](image-url) Absorption ratios ($A_{730}/A_{525}$) of (A) Hg$^{2+}$-DPL-AuNPs and (B) As$^{3+}$-DPL-AuNPs as a function of temperature (10–70 °C), and absorption ratios ($A_{730}/A_{525}$) of (C) Hg$^{2+}$-DPL-AuNPs and (D) As$^{3+}$-DPL-AuNPs as a function of NaCl concentration (0–500 mM).
mercuric or arsenic ions was increased (Fig. 8). Additionally, the absorbance at 730 nm increased and that at 525 nm concomitantly decreased as the concentration of mercuric or arsenic ions in the DPL-AuNP solutions was increased (0.00, 0.20, 0.40, 0.60, 0.80, 1.00, 1.20, 1.40 μM for Hg2+ or As3+). The absorbance ratio for each different concentration of each ion was measured in triplicate. Linear regression analysis of the calibration curve showed good linearity (r2 = 0.9940 for Hg2+, and 0.9986 for As3+) within a linear dynamic range of 0.0–1.4 μM. The limits of detection (LODs) of this probe for Hg2+ and As3+ in tap and pond water samples were found to be 0.5 and 0.7 nM, respectively using [3σ/slope].

3.6 Application of the DPL-AuNP probe in the analyses of real samples
To validate the present assay, its colorimetric responses in real tap water, and pond water samples spiked with 1.0, 5.0, and 10.0 μM Hg2+ (and As3+) were analyzed using the DPL-AuNP probe. As shown in Table 1, the analytical results of the proposed probe were nearly identical to the amounts of Hg2+ (or As3+) with which the samples were spiked. Thus, the present AuNP-based probe allows the consecutive dual determination of Hg2+ and As3+ ions at a sensitivity equal to that of established instrumental methods, but is more advantageous in terms of simplicity, cost, and time.

The results of previously reported instrumental methods and NP assays for the detection of Hg2+ and As3+ ions are compared...
Table 1  Concentrations of As$^{3+}$ and Hg$^{2+}$ in spiked tap water, pond water, waste water, and river water samples measured using the present DPL-AuNP colorimetric probe. These analytical results were confirmed by DMA and ICP-MS

Table 2  Comparison of present colorimetric method and other detection methods for dual determination of Hg$^{2+}$ and As$^{3+}$ ion in water samples

| Probe             | Sensing principles | LODs (Hg$^{2+}$/As$^{3+}$) | Ref. |
|-------------------|--------------------|-----------------------------|------|
| Hg$^{2+}$         | OPD-AgNPs$^{a}$    | 0.35 µM                     | 14   |
|                   | Met-AgNPs$^{a}$    | 20 nM                       | 15   |
|                   | AgNPs$^{c}$        | 1.3 µM                      | 16   |
|                   | NTA-AuNPs$^{d}$    | 7 nM                        | 17   |
|                   | OPD-AuNPs$^{d}$    | 5.0 nM                      | 18   |
|                   | N-T-AuNPs$^{f}$    | 0.8 nM                      | 19   |
|                   | AuNPs$^{d}$        | 0.24 nM                     | 20   |
|                   | Aptamer-Ag@SiO$_2$ NPs$^{h}$ | 0.33 nM | 21 |
|                   | N-doped CNPs$^{d}$ | 2.3 nM                      | 22   |
| As$^{3+}$         | PEG-AgNPs$^{d}$    | 13.3 nM                     | 23   |
|                   | Aptamer-AgNPs$^{d}$| 80.1 nM                     | 24   |
|                   | AuNPs              | 133.4 nM                    | 25   |
|                   | GSH-DTT-Cys-PDCA-AuNPs$^{g}$ | 33.3 nM | 26 |
|                   | Rano-CuNPs$^{d}$   | 16 nM                       | 27   |
| Hg$^{2+}$/As$^{3+}$| DTT-PCDA-AuNPs & Lys-AuNPs$^{a}$ | 10.8 nM/710 nM | 28 |
|                   | DPL-AuNPs          | 0.5 nM/0.7 nM               | This study |

$^{a}$ AgNPs conjugated with 2-aminopyrimidine-4,6-diol. $b$ AgNPs conjugated with methionine. $c$ Ag nanoparticles. $d$ AuNPs conjugated with 3-nitro-1H-1,2,4-triazole. $e$ AuNPs in the presence of o-phenylenediamine. $f$ AuNPs conjugated with a thymine derivative modified with quaternary ammonium salt. $g$ Au nanostars. $h$ Aptamer-Ag@SiO$_2$NPs and thiazole orange buffer solution. $i$ N-doped carbon nanoparticles, CNPs. $j$ AgNPs conjugated with polyethylene glycol. $k$ AgNPs conjugated with aptamer. $l$ AuNPs capped with citrates. $m$ AuNPs conjugated with glutathione-dithiothreitol-cysteine 2,6-pyridinedicarboxylic acid. $n$ CuNPs conjugated with ranolazine. $o$ AuNPs conjugated with dithiothreitol-10,12-pentacosadiynoic acid and AuNPs conjugated with lysine.

in Table 2, revealing that the current colorimetric DPL-AuNP probe enables the dual determination of Hg$^{2+}$ and As$^{3+}$ ions with excellent sensitivity in aqueous samples.

4 Conclusions

AuNPs of a specific size (~20 nm) were prepared via the straightforward citrate reduction of HAuCl$_4$, and DPL-AuNPs were then prepared via a ligand-exchange reaction between DPL and citrate-capped AuNPs. AuNPs conjugated with DPL were developed as a highly sensitive colorimetric dual probe for Hg$^{2+}$ and As$^{3+}$ ions. The sensing mechanism of this colorimetric probe involves the aggregation of the DPL-AuNPs in the presence of Hg$^{2+}$ and As$^{3+}$ ions. The DPL-AuNPs binding sites for Hg$^{2+}$ (As$^{3+}$) ions were elucidated by FTIR spectroscopy, high-resolution XPS, and TOF-SIMS, and both ions were found to be selectively coordinated by the nitrogen and oxygen atoms of the conjugated DPL as a function of the pH. When Hg$^{2+}$ (As$^{3+}$) ions coordinate with AuNP-bound DPL, the interparticle distance decreases, which induces aggregation, resulting in

a significant color change from wine red to dark midnight blue. Various other ions did not interfere with the determination of Hg$^{2+}$ or As$^{3+}$, even at concentrations 100-fold higher than those of Hg$^{2+}$ or As$^{3+}$. This dual probe offers simple, highly sensitive, highly selective, and on-site sequential monitoring of Hg$^{2+}$ and As$^{3+}$ ions in environmental samples, and allows Hg$^{2+}$ and As$^{3+}$ ion concentrations as low as 0.5 and 0.7 nM, respectively to be visually detected within 2 min. Notably, Hg$^{2+}$ (As$^{3+}$) ions were found to exhibit significant binding affinity and specificity for the DPL-AuNP structure, providing valuable insights for the molecular design and realization of more efficient metal ion probes in the future.
