Abstract

Category theory provides a compact method of encoding mathematical structures in a uniform way, thereby enabling the use of general theorems on, for example, equivalence and universal constructions. In this article we develop the method of additional structures on the objects of a monoidal Kleisli category. It is proposed to consider any uniform class of information transformers (ITs) as a family of morphisms of a category that satisfy certain set of axioms. This makes it possible to study in a uniform way different types of ITs, e.g., statistical, multivalued, and fuzzy ITs. Proposed axioms define a category of ITs as a monoidal category that contains a subcategory (of deterministic ITs) with finite products. Besides, it is shown that many categories of ITs can be constructed as Kleisli categories with additional structures.
1 Introduction

Currently the growing interest is attracted to various mathematical ways of describing uncertainty, most of them being different from the probabilistic one, (e.g., based on the apparatus of fuzzy sets). For adequate theoretical study of the corresponding “nonstochastic” systems of information transforming and, in particular, for the study of important notions, such as sufficiency, informativeness, etc., we need to develop an approach general enough to describe different classes of information transforming systems in a uniform way.

It is convenient to consider different systems that take place in information acquiring and processing as particular cases of so-called information transformers (ITs). Besides, it is useful to work with families of ITs in which certain operations, e.g., sequential and parallel compositions are defined.

It was noticed fairly long ago [1–5], that the adequate algebraic structure for describing information transformers (initially for the study of statistical experiments) is the structure of category [6–9].

Definition 1.1 A category is a quadruple $(\text{Ob}, \text{Hom}, \text{id}, \circ)$ consisting of:

(C1) a class $\text{Ob}$ of objects;

(C2) for each ordered pair $(A, B)$ of objects a set $\text{Hom}(A, B)$ of morphisms;

(C3) for each object $A$ a morphism $\text{id}_A \in \text{Hom}(A, A)$, the identity of $A$;

(C4) a composition law associating to each pair of morphisms $f \in \text{Hom}(A, B)$ and $g \in \text{Hom}(B, C)$ a morphism $g \circ f \in \text{Hom}(A, C)$; which is such that:

(M1) $h \circ (g \circ f) = (h \circ g) \circ f$ for all $f \in \text{Hom}(A, B)$, $g \in \text{Hom}(B, C)$ and $h \in \text{Hom}(C, D)$;

(M2) $\text{id}_B \circ f = f \circ \text{id}_A = f$ for all $f \in \text{Hom}(A, B)$;

(M3) the sets $\text{Hom}(A, B)$ are pairwise disjoint.

This last axiom is necessary so that given a morphism we can identify its domain $A$ and codomain $B$, however it can always be satisfied by replacing $\text{Hom}(A, B)$ by the set $\text{Hom}(A, B) \times \{\{A\}, \{B\}\}$.

A morphism $a: A \to B$ is called isomorphism if there exists a morphism $b: B \to A$ such that $a \circ b = i_B$ and $b \circ a = i_A$. In this case objects $A$ and $B$ are called isomorphic.

Morphisms $a: D \to A$ and $b: D \to B$ are called isomorphic if there exists an isomorphism $c: A \to B$ such that $c \circ a = b$. 

An object $Z$ is called *terminal* object if for any object $A$ there exists a unique morphism from $A$ to $Z$, which is denoted $z_A: A \to Z$ in what follows.

A category $D$ is called a *subcategory* of a category $C$ if $\text{Ob}(D) \subseteq \text{Ob}(C)$, $\text{Ar}(D) \subseteq \text{Ar}(C)$, and morphism composition in $D$ coincide with their composition in $C$.

It is said that a category has (pairwise) products if for every pair of objects $A$ and $B$ there exists their product, that is, an object $A \times B$ and a pair of morphisms $\pi_{A,B}: A \times B \to A$ and $\nu_{A,B}: A \times B \to B$, called projections, such that for any object $D$ and for any pair of morphisms $a: D \to A$ and $b: D \to B$ there exists a unique morphism $c: D \to A \times B$, satisfying the following conditions:

\[
\pi_{A,B} \circ c = a, \quad \nu_{A,B} \circ c = b. \tag{1}
\]

We call such morphism $c$ the *product of morphisms* $a$ and $b$ and denote it $a \times b$.

It is easily seen that existence of products in a category implies the following equality:

\[
(a \times b) \circ d = (a \circ d) \times (b \circ d). \tag{2}
\]

In a category with products, for two arbitrary morphisms $a: A \to C$ and $b: B \to D$ one can define the morphism $a \times b$:

\[
a \times b: A \times B \to C \times D, \quad a \times b \overset{\text{def}}{=} (a \circ \pi_{A,B}) \times (b \circ \nu_{A,B}). \tag{3}
\]

This definition and (1) obviously imply that the morphism $c = a \times b$ satisfy the following conditions:

\[
\pi_{C,D} \circ c = a \circ \pi_{A,B}, \quad \nu_{C,D} \circ c = b \circ \nu_{A,B}. \tag{4}
\]

Moreover, $c = a \times b$ is the only morphism satisfying conditions (4).

It is also easily seen that (2) and (3) imply the following equality:

\[
(a \times b) \circ (c \times d) = (a \circ c) \times (b \circ d). \tag{5}
\]

Suppose $A \times B$ and $B \times A$ are two products of objects $A$ and $B$ taken in different order. By the properties of products, the objects $A \times B$ and $B \times A$ are isomorphic and the natural isomorphism is

\[
\sigma_{A,B}: A \times B \to B \times A, \quad \sigma_{A,B} \overset{\text{def}}{=} \nu_{A,B} \times \pi_{A,B}. \tag{6}
\]
Moreover, for any object $D$ and for any morphisms $a: D \to A$ and $b: D \to B$, the morphisms $a * b$ and $b * a$ are isomorphic, that is,

$$\sigma_{A,B} \circ (a * b) = b * a. \quad (7)$$

Similarly, by the properties of products, the objects $(A \times B) \times C$ and $A \times (B \times C)$ are isomorphic. Let

$$\alpha_{A,B,C}: (A \times B) \times C \to A \times (B \times C)$$

be the corresponding natural isomorphism. Its “explicit” form is:

$$\alpha_{A,B,C} \overset{\text{def}}{=} (\pi_A \circ \pi_{A \times B}) \ast \left( (\nu_A \circ \pi_{A \times B}) \ast \nu_{A \times B} \right). \quad (8)$$

Then for any object $D$ and for any morphisms $a: D \to A$, $b: D \to B$, and $c: D \to C$ we have

$$\alpha_{A,B,C} \circ ((a * b) * c) = a * (b * c). \quad (9)$$

**Examples.**

1.1. The classic example is **Sets**, the category with sets as objects and functions as morphisms, and the usual composition of functions as composition. But lots of the time in mathematics one is some category or other, e.g.:

- **Vect**$_k$ — vector spaces over a field $k$ as objects; $k$-linear maps as morphisms;
- **Group** — groups as objects, homomorphisms as morphisms;
- **Top** — topological spaces as objects, continuous functions as morphisms;
- **Diff** — smooth manifolds as objects, smooth maps as morphisms;
- **Ring** — rings as objects, ring homomorphisms as morphisms;

or in physics:

- **Symp** — symplectic manifolds as objects, symplectomorphisms as morphisms;
- **Poiss** — Poisson manifolds as objects, Poisson maps as morphisms;
- **Hilb** — Hilbert spaces as objects, unitary operators as morphisms.

1.2. The typical way to think about symmetry is with the concept of a "group". But to get an idea of symmetry that’s really up to the demands put on it by modern mathematics and physics, we need — at the very least — to work with a "category" of symmetries, rather than a group of symmetries.
To see this, first ask: what is a category with one object? It is a — "monoid". The "usual" definition of a monoid is like this: a set \( M \) with an associative binary product and a unit element \( 1 \) such that \( al = la = a \) for all \( a \) in \( M \). Monoids abound in mathematics; they are in a sense the most primitive interesting algebraic structures.

To check that a category with one object is "essentially just a monoid", note that if our category \( C \) has one object \( x \), the set \( \text{Hom}(x, x) \) of all morphisms from \( x \) to \( x \) is indeed a set with an associative binary product, namely composition, and a unit element, namely \( \text{id}_x \).

How about categories in which every morphism is invertible? We say a morphism \( f : x \to y \) in a category has inverse \( g : y \to x \) if \( f \circ g = \text{id}_y \) and \( g \circ f = \text{id}_x \). Well, a category in which every morphism is invertible is called a "groupoid".

Finally, a group is a category with one object in which every morphism is invertible. It’s both a monoid and a groupoid!

When we use groups in physics to describe symmetry, we think of each element \( g \) of the group \( G \) as a "process". The element \( 1 \) corresponds to the "process of doing nothing at all". We can compose processes \( g \) and \( h \) — do \( h \) and then \( g \) — and get the product \( g \circ h \). Crucially, every process \( g \) can be "undone" using its inverse \( g^{-1} \).

So: a monoid is like a group, but the "symmetries" no longer need be invertible; a category is like a monoid, but the "symmetries" no longer need to be composable.

1.3. The operation of "evolving initial data from one spacelike slice to another" is a good example of a "partially defined" process: it only applies to initial data on that particular spacelike slice. So dynamics in special or general relativity is most naturally described using groupoids. Only after pretending that all the spacelike slices are the same can we pretend we are using a group. It is very common to pretend that groupoids are groups, since groups are more familiar, but often insight is lost in the process. Also, one can only pretend a groupoid is a group if all its objects are isomorphic. Groupoids really are more general.

In the work [10] we undertake an attempt to formulate the method of categorical extension of the theory of a group \( G \) as follows:

Let \( G \) be a group. Then \( G \) is merely the visible part of a certain category \( K \) which is invisible to the naked eye. More precisely, there exists a certain category \( K \) (the train of the group \( G \)) such that the group itself is the automorphism group of a certain object \( V \), while the semigroup \( \Gamma \)
is the semigroup of endomorphisms of this same object. Furthermore, each representation $\rho$ of $G'$ on a space $H$ can be extended to a representation of the category $K$. In other words, for each objects $W$ of the category $K$ we can construct a linear space $T(W)$ and for each morphism $P : W \to W'$ we can construct a linear operator $\tau(P) : T(W) \to T(W')$ such that for any morphisms $P : W \to W'$ and $Q : W' \to W''$ we have

$$\tau(QP) = \tau(Q)\tau(P)$$

with $T(V) = H$, and for all $g \in G$ the operators $\tau(g)$ and $\rho(g)$ are the same.

We note that all the spaces $T(W)$ and all the operators $\tau(p)$ “grow out of” the one and only representation $\rho$ of $G$ and the one and only space $H$.

So: in contrast to a set, which consists of a static collection of "things", a category consists not only of objects or "things" but also morphisms which can viewed as "processes" transforming one thing into another. Similarly, in a 2-category, the 2-morphisms can be regarded as "processes between processes", and so on. The eventual goal of basing mathematics upon omega-categories is thus to allow us the freedom to think of any process as the sort of thing higher-level processes can go between. By the way, it should also be very interesting to consider "Z-categories" (where $Z$ denotes the integers), having $j$-morphisms not only for $j = 0, 1, 2, ...$ but also for negative $j$. Then we may also think of any thing as a kind of process.

**Definition 1.2** Let $X$ and $Y$ be two categories. A functor from $X$ to $Y$ is a family of functions $F$ which associates to each object $A$ in $X$ an object $FA$ in $Y$ and to each morphism $f \in \text{Hom}_X(A, B)$ a morphism $Ff \in \text{Hom}_Y(FA, FB)$, and which is such that:

1. $(F1)$ $F(g \circ f) = Fg \circ Ff$ for all $f \in \text{Hom}_X(A, B)$ and $g \in \text{Hom}_Y(B, C)$;
2. $(F2)$ $F \text{id}_A = \text{id}_{FA}$ for all $A \in \text{Ob}(X)$.

There is the definition of left and right adjoint functors. In the following we shall need two such adjoint constructions. First, in a given category the left adjoint of the diagonal functor (if it exists) is called the coproduct and the right adjoint (if it exists) is called the product: in $\text{Sets}$ the product is the Cartesian product and the coproduct is the disjoint union. Second, let the category $X$ be concrete over some category $A$ in the sense that there exists a faithful functor $U$ from $X$ to $A$, usually called the forgetful functor. The left adjoint to this functor (if it exists) is then called the free functor.
A standard example is the forgetful functor from complete metric spaces to metric spaces, whose left adjoint in the completion functor. On the next higher level of abstraction the notion of a natural transformation is settled. It is a kind of a function between functors and is defined as follows.

**Definition 1.3** Let $F : X \to Y$ and $G : X \to Y$ be two functors. A natural transformation $\alpha : F \to G$ is given by the following data.

For every object $A$ in $X$ there is a morphism $\alpha_A : F(A) \to G(A)$ in $Y$ such that for every morphism $f : A \to B$ in $X$ the following diagram is commutative

$$
\begin{array}{ccc}
F(A) & \xrightarrow{\alpha_A} & G(A) \\
F(f) \downarrow & & \downarrow G(f) \\
F(B) & \xrightarrow{\alpha_B} & G(B).
\end{array}
$$

Commutativity means (in terms of equations) that the following compositions of morphisms are equal: $G(f) \circ \alpha_A = \alpha_B \circ F(f)$.

The morphisms $\alpha_A, A \in \text{Obj}(A)$, are called the components of the natural transformation $\alpha$.

**Examples.**

1.4. So, we can certainly speak, as before, of the "equality" of categories. We can also speak of the "isomorphism" of categories: an isomorphism between $C$ and $D$ is a functor $F : C \to D$ for which there is an inverse functor $G : D \to C$. I.e., $FG$ is the identity functor on $C$ and $GF$ the identity on $D$, where we define the composition of functors in the obvious way. But because we also have natural transformations, we can also define a subtler notion, the "equivalence" of categories. An equivalence is a functor $F : C \to D$ together with a functor $G : D \to C$ and natural isomorphisms $a : FG \to 1_C$ and $b : GF \to 1_D$. A "natural isomorphism" is a natural transformation which has an inverse.

1.5. As we can "relax" the notion of equality to the notion of isomorphism when we pass from sets to categories, we can relax the condition that $FG$ and $GF$ equal identity functors to the condition that they be isomorphic to identity functor when we pass from categories to the 2-category $\text{Cat}$. We need to have the natural transformations to be able to speak of functors being isomorphic, just as we needed functions to be able to speak of sets being isomorphic. In fact, with each extra level in the theory of $n$-categories, we will be able to come up with a still more refined notion of "$n$-equivalence" in this way.
Analysis of general properties for the classes of linear, multivalued, and fuzzy information transformers, studied in [5, 11–18], allowed to extract general features shared by all these classes. Namely, each of these classes can be considered as a family of morphisms in an appropriate category, where the composition of information transformers corresponds to their “consecutive application.” Each category of ITs (or IT-category) contains a subcategory (of so called, deterministic ITs) that has products. Moreover, the operation of morphism product is extended in a “coherent way” to the whole category of ITs.

The works [19–22] undertook an attempt to formulate the method of additional structures as a set of “elementary” axioms for a category, which would be sufficient for an abstract expression of the basic concepts of the theory of information transformers and for study of informativeness, decision problems, etc. This paper proposes another, significantly more compact axiomatic for a category of ITs. According to the method of additional structures on the objects of a category of ITs it is defined in effect as a monoidal category [6, 8], containing a subcategory (of deterministic ITs) with finite products.

Among the basic concepts connected to information transformers there is one that plays an important role in the uniform construction of a wide spectrum of IT-categories — the concept of distribution. Indeed, fairly often an IT \( a: \mathcal{A} \to \mathcal{B} \) can be represented by a mapping from \( \mathcal{A} \) to the “space of distributions” on \( \mathcal{B} \) (see, e.g., [11–18]). For example, a probabilistic transition distribution (an IT in the category of stochastic ITs) can be represented by a certain measurable mapping from \( \mathcal{A} \) to the space of distributions on \( \mathcal{B} \). This observation suggests to construct a category of ITs as a Kleisli category [6,23], arising from the following components: an obvious category of deterministic ITs; a functor that takes an object \( \mathcal{A} \) to the object of “distributions” on \( \mathcal{A} \); and a natural transformation of functors, describing an “independent product of distributions”.

It appears that rather general axiomatic theory, obtained this way, makes it possible to express in terms of IT-categories basic concepts for information transformers and to derive their main properties.

Of course, the most developed theory of uncertainty is probability theory (and statistics, based on probability). Certainly, mathematical statistics accumulated a rich conceptual experience. It introduced and deeply investigated such notions as joint and conditional distributions, independence, sufficiency, and others.
At the same time, it appears that all these concepts have very abstract meaning and hence, they can be treated in terms of alternative (i.e., not probabilistic) approaches to the description of uncertainty. In fact, the basic notions of probability theory and statistics, as well as the methodology and results, are easily extended to other theories dealing with uncertainty. In [11–18] it is shown that a rather substantive decision theory may be constructed even on the very moderate basis of multivalued or fuzzy maps.

The approach developed in this paper allows to express easily in terms of IT-categories such concepts as distribution, joint and conditional distributions, independence, and others. It is shown that on the basis of these concepts it is possible to formulate fairly general statement of decision-making problem with a prior information, which generalizes the Bayesian approach in the theory of statistical decisions. Moreover, the Bayesian principle, derived below, like its statistical prototype [24], reduces the problem of optimal decision strategy construction to a significantly simpler problem of finding optimal decision for a posterior distribution.

Among the most important concepts in categories of ITs is the concept of (relative) informativeness of information transformers. There are two different approaches to the concept of informativeness.

One of these approaches is based on analyzing the “relative positions” of information transformers in the corresponding mathematical structure. Roughly speaking, one information transformer is regarded as more informative than another one if with the aid of an additional information transformer the former one can be “transformed” to an IT, which is similar to (or more “accurate” than) the latter one. In fact, this means that all the information that can be obtained from the latter information transformer can be extracted from the former one as well.

The other approach to informativeness is based on treating information transformers as data sources for decision-making problems. Here, one information transformer is said to be semantically more informative than another if it provides better quality of decision making. Obviously, the notion of semantical informativeness depends on the class of decision-making problems under consideration.

In the classical researches of Blackwell [25, 26] the correspondence between informativeness (Blackwell sufficiency) and semantical informativeness (Blackwell informativeness) were investigated in a statistical context. These studies were extended by Morse, Sacsteder, and Chentsov [1–4] who applied the category theory techniques to their studies of statistical systems.
It is interesting, that under very general conditions the relations of informativeness and semantical informativeness (with respect to a certain class of decision-making problems) coincide. Moreover, in some categories of ITs it is possible to point out one special decision problem, such that the resulting semantical informativeness coincides with informativeness.

Analysis of classes of equivalent (with respect to informativeness) information transformers shows that they form a partially ordered Abelian monoid with the smallest (also neutral) and the largest elements.

One of the objectives of this paper is to show that the basic constructions and propositions of probability theory and statistics playing the fundamental role in decision-making problems have meaningful counterparts in terms of IT-categories. Furthermore, some definitions and propositions (for example, the notion of conditional distribution and the Bayesian principle) in terms of IT-categories often have more transparent meanings. This provides an opportunity to look at the well known results from a different angle. What is even more significant, it makes it possible to apply the methodology of statistical decision-making in an alternative (not probabilistic) context.

Approaches, proposed in this work may provide a background for construction and study of new classes of ITs, in particular, dynamical non-deterministic ITs, which may provide an adequate description for information flows and information interactions evolving in time. Besides, a uniform approach to problems of information transformations may be useful for better understanding of information processes that take place in complex artificial and natural systems.

2 The method of additional structures on the objects of a category

2.1 Basic definitions

To use the categorical language more effectively we introduce general concept of an additional structure on objects of a category. This is the concept of concrete category but over any category [19–22].

In a category, two objects $x$ and $y$ can be equal or not equal, but they can be isomorphic or not, and if they are isomorphic, they can be isomorphic in many different ways. An isomorphism between $x$ and $y$ is simply a morphism $f : x \to y$ which has an inverse $g : y \to x$, such that $f \circ g = \text{id}_y$ and $g \circ f = \text{id}_x$. 
In the category **Sets** an isomorphism is just a one-to-one and onto function, i.e. a bijection. If we know two sets $x$ and $y$ are isomorphic we know that they are “the same in a way”, even if they are not equal. But specifying an isomorphism $f : x \rightarrow y$ does more than say $x$ and $y$ are the same in a way; it specifies a particular way to regard $x$ and $y$ as the same.

In short, while equality is a yes-or-no matter, a mere property, an isomorphism is a structure. It is quite typical, as we climb the categorical latter (here from elements of a set to objects of a category) for properties to be reinterpreted as structures.

**Definition 2.1** We tell that a functor $F : C \rightarrow C'$ define a additional $C-$structure on objects of the category $C'$ if

1. $\forall X, Y \in \text{Ob}(C)$ the map $F : C(X,Y) \rightarrow C'(F(X),F(Y))$ is injective,

2. $\forall X \in \text{Ob}(C), Y \in \text{Ob}(C')$ and an isomorphism $u : Y \rightarrow F(X)$ there is an object $\tilde{Y} \in \text{Ob}$ and an isomorphism $\tilde{u} : \tilde{Y} \rightarrow X$ such that $F(\tilde{Y}) = Y$ and $F(\tilde{u}) = u$.

Such functor is called a forgetful functor.

Almost all usual mathematical structures are structure on sets in this sense and there are corresponding forgetful functors to the category **Sets** of sets.

A forgetful functor $F : C \rightarrow M(C')$ defines a $C$-structure on morphisms of the category $C'$.

For our general structures we can define usual construction:

- inverse and direct images of structures;
- restrictions on subobjects,
- different products of structures.

We can define the category $Str(C)$ of forgetful functors to the category $C$. It is a full subcategory of the category $Cat/C$ of all categories over $C$.

Some properties of structures (= forgetful functors):

- In the category $Str(C)$ the (bundle) product always exists. It gives a “union” structures.
- Any functor \( f : \mathcal{C} \to \mathcal{C}' \) transfers structures to inverse direction, i.e. it defines the functor

\[
f^* : \text{Str}(\mathcal{C}') \to \text{Str}(\mathcal{C}) : F \mapsto f^* F.
\]

- For a forgetful functor \( F : \mathcal{C} \to \mathcal{C}' \) the functors

\[
(F \circ) = \text{Funct}(id, F) : \text{Funct}(\mathcal{B}, \mathcal{C}) \to \text{Funct}(\mathcal{B}, \mathcal{C}')
\]

\[
(\circ F) = \text{Funct}(F, id) : \text{Funct}(\mathcal{C}', \mathcal{B}) \to \text{Funct}(\mathcal{C}, \mathcal{B})
\]

are forgetful functors.

- One of constructions which transfers structure \( F : \mathcal{C} \to \text{Sets} \) defined on sets to objects of any category \( \mathcal{B} \), is the functor

\[
h : \mathcal{B} \to \text{Funct}(\mathcal{B}', \text{Sets}) : B \mapsto h_B.
\]

Thus we have

\[
\begin{array}{ccc}
h_B^\ast \mathcal{C} & \longrightarrow & \mathcal{C} \\
\downarrow & & \downarrow F \\
\mathcal{B}' & \xrightarrow{h_B} & \text{Sets}
\end{array}
\]

- If a functor \( A : \mathcal{B} \to \mathcal{C} \) is injective on morphisms (the condition (1) in the definition of forgetful functor) then a forgetful functor \( F : \mathcal{B}' \to \mathcal{C} \) and an equivalence \( i : \mathcal{B} \to \mathcal{B}' \) exist, such that the following diagram is commutative

\[
\begin{array}{ccc}
\mathcal{B} & \longrightarrow & \mathcal{C} \\
\downarrow & \searrow F \\
\mathcal{B}' & & \mathcal{C}
\end{array}
\]

### 2.2 Structures on Topological Spaces

Among of structures on topological spaces we can select that, which is compatible with the topology. Let \( \text{Top} \) be a category of some topological spaces with a forgetful functor \( F : \text{Top} \to \text{Sets} \).

The categories associated with a topological space \( T \in \text{Ob(\text{Top})} \) as follows:

- The category \( \mathcal{T}(T) \), where \( \text{Ob}(\mathcal{T}(T)) \) is the set of all open subsets of \( T \), and \( \text{Mor}(\mathcal{T}(T)) \) is all their inclusions.
The category (pseudogroup) $\mathcal{P}(T)$, where $\text{Ob}(\mathcal{P}(T))$ is the set of all open subsets of $T$, and $\text{Mor}(\mathcal{P}(T))$ is all their homeomorphisms.

Functors $\mathcal{T}(T)^\circ \to \text{Set}$ are called presheaves of sets on $T$. Some of them are called sheaves. Thus we have the inclusions

$$\text{Sh}(T) \subset \text{Presh}(T) \subset \text{Funct}(\mathcal{T}(T), \text{Sets}).$$

A Grothendieck topology on a category is defined by saying which families of maps into an object constitute a covering of the object and certain axioms are fulfill. A category together with a Grothendieck topology on it is called a site. For a site $\mathcal{C}$ one define the full subcategory $\text{Sh}(\mathcal{C}) \subset \text{Presh}(\mathcal{C}) = \text{Funct}(\mathcal{C}^\circ, \text{Set})$. The objects of $\text{Funct}(\mathcal{C}^\circ, \text{Set})$ are called presheaves on the site $\mathcal{C}$, and the objects of $\text{Sh}(\mathcal{C})$ are called sheaves on $\mathcal{C}$.

For any category there exists the finest topology such that the all representable presheaves are sheaves. It is called the canonical Grothendieck topology. Topos is a category which is equivalent to the category of sheaves for the canonical topology on them.

Hence, the topology is already transfered on a category so now it is natural to consider on language of toposes and sheaves all questions connected to local properties.

Here we shall not consider local structures on toposes in general, and we shall restrict ourselves with the consideration of the elementary case of the category $\text{Top}$.

**Definition 2.2** A structure defined by a forgetful functor $f : \mathcal{C} \to \text{Top}$ is called a local structure if

$$\forall C \in \text{Obj}(\mathcal{C}) \text{ and any inclusion map } i : U \to f(C) \text{ of the open subset } U \text{ an object } \tilde{U} \in \text{Ob}(\mathcal{C}) \text{ and a morphism } \tilde{i} \in \mathcal{C}(\tilde{U}, C) \text{ exist such that } f(\tilde{U}) = U f(\tilde{i}) = i. \text{ This } \mathcal{C} - \text{structure } \tilde{U} \text{ is denoted by } C|U \text{ and called a restriction of } C \text{ on } U.$$

In other words we can restrict ourselves with local structures on open subsets.

For a local structure $F : \mathcal{C} \to \text{Top}$ and each object $X \in \text{Obj}(\text{Top})$ there is the presheaf of categories

$$\mathcal{T}(X)^\circ \to \text{Cat} : U \mapsto F^{-1}(U, id_U).$$

Often this presheaf is a sheaf.
2.3 Structures on Smooth Manifolds

Let \( \mathcal{M} \) be the category of smooth (\( \infty \)-differentiable) manifolds with forgetful functor \( f: \mathcal{M} \to \text{Top} \), which defines a local structure and the presheaves of these structures are sheaves. On the category \( \mathcal{M} \) there is the tangent functor \( T: \mathcal{M} \to \mathcal{M}: M \mapsto T(M) \).

Its iterations give us almost all interesting functors on \( \mathcal{M} \). Among them we shall note the following:

- The cotangent functor \( T^*: \mathcal{M} \to \mathcal{M}: M \mapsto T^*(M) \).
- For a manifold \( M \) and natural number \( k = 0, 1, \ldots \) the functor of \( k \)-jets \( J^k: \mathcal{M} \to \mathcal{M}: N \mapsto J^k(M, N) \).
- For a manifold \( M, x \in M \), and natural number \( k = 0, 1, \ldots \) the functor of \( k \)-jets at the point \( x \) \( J^k_x: \mathcal{M} \to \mathcal{M}.J^k_x(M, N) \).

Any category \( \mathcal{C} \) of structures on smooth manifolds (or on \( \mathcal{M}/ \)) has an additional structure, which give us a possibility to define "smooth families of morphisms".

**Definition 2.3** Let \( M, M', M'' \in \mathcal{M} \). A map

\[
\Phi: M \to \mathcal{M}(M', M''): x \mapsto \Phi_x
\]

is called a smooth family of morphisms if there exists a smooth map \( \phi: M \times M' \to M'' \) such that

\[
\forall x \in M, \ x' \in M' \quad \Phi_x(x') = \phi(x, x').
\]

Thus we get the class of categories with smooth families and it appears the natural condition on functors.

**Definition 2.4** A functor is called a smooth functor if it maps each smooth family to a smooth family.

Of course all functors \( T, T^*, J^k, J^k_x \) are smooth.
2.4 Double Categories as additional structure on categories

In any category $C$ with bundle products for some morphisms we can define so-called intern categories. This is a monoid in the multiplicative category $\mathcal{C}//O$ of pairs of (special) morphisms $D, R : M \to O$ with the bundle product:

for $\xi = (D, R : M \to O)$ and $\xi' = (D', R' : M \to O)$ we get $\xi \ast \xi' = (D \circ \pi_1, R' \circ \pi_2 : M \times O M' \to O)$ where the unit objects $\text{id}_M : 0 \to M$ and $\text{id}_{M'} : 0 \to M'$ and the following diagram is commutative

$$
\begin{array}{ccc}
M \times O M' & \xrightarrow{\pi_2} & M' \\
\downarrow \pi_1 & & \downarrow R' \\
M & \xrightarrow{R} & O
\end{array}
$$

So an intern category is an object $\xi = (D, R : M \to O)$ with a multiplication $\mu : \xi \ast \xi' \to \xi$ and the unit $\text{id}_M : O \to M$.

Now we consider such intern category as the category $\text{Cat}$ of categories and will call it as double categories [20].

**Definition 2.5** A double category $D$ consists of the following:

1. A category $D_0$ of objects $\text{Obj}(D_0)$ and morphisms $\text{Mor}(D_0)$ of 0-level.
2. A category $D_1$ of morphisms $\text{Obj}(D_1)$ of 1-level and morphisms $\text{Mor}(D_1)$ of 2-level.
3. Two functors $d, r : D_1 \xrightarrow{\cong} D_0$.
4. A composition functor $\ast : D_1 \times_{D_0} D_1 \to D_1$

where the bundle product is defined by commutative diagram

$$
\begin{array}{ccc}
D_1 \times_{D_0} D_1 & \xrightarrow{\pi_2} & D_1 \\
\downarrow \pi_1 & & \downarrow d \\
D_1 & \xrightarrow{r} & D_0
\end{array}
$$

(5) A unit functor $\text{ID} : D_0 \to D_1$, which is a section of $d, r$.

There are strong and weak double categories.

Now we see that for two objects $A, B \in \text{Obj}(D_0)$ there are 0-level morphisms $D_0(A,B)$ which we note by ordinary arrows $f : A \to B$, and 1-level
morphisms $D_{(1)}(A, B)$, which we note by the arrows $\xi : A \Rightarrow B$ for $A = d(\xi)$ and $B = r(\xi)$. So with a 2-level morphism $\alpha : \xi \to \xi'$, where $\xi : A \Rightarrow B$ and $\xi' : A' \Rightarrow B'$ we can associate the following diagram

$$
\begin{array}{ccc}
A & \xrightarrow{\xi} & B \\
\downarrow d(\alpha) & & \downarrow r(\alpha) \\
A' & \xrightarrow{\xi'} & B'
\end{array}
$$

and arrow $\alpha : d(\alpha) \Rightarrow r(\alpha)$.

On each level we have the corresponding compositions:

0-level $(A \xrightarrow{f} B \xrightarrow{g} C) \mapsto g \circ f : A \to C$

$\xi \xrightarrow{\alpha} \eta \xrightarrow{\beta} \zeta \mapsto \beta \circ \alpha : \xi \to \zeta$

1-level $(A \xRightarrow{\xi} B \xRightarrow{\eta} C) \mapsto \eta \ast \xi : A \Rightarrow C$

2-level $(f \Rightarrow g \Rightarrow h) \mapsto \beta \ast \alpha : f \Rightarrow h$

The composition on 2-level associated with the diagram

$$
\begin{array}{ccc}
A & \xrightarrow{\xi} & B \\
\downarrow d(\alpha) & & \downarrow r(\alpha) \\
A' & \xrightarrow{\xi'} & B' \\
\downarrow d(\alpha') & & \downarrow r(\alpha') \\
A'' & \xrightarrow{\xi''} & B''
\end{array}
$$

Thus, a double category $D$ consists of

- four sets $\text{Obj}(D_0)$, $\text{Mor}(D_0)$, $\text{Obj}(D_1)$, $\text{Mor}(D_1)$, and eight maps of type $d, r$

  $$
  \begin{array}{c}
  \text{Obj}(D_1) \equiv \text{Mor}(D_1) \\
  \downarrow \downarrow \\
  \text{Obj}(D_0) \equiv \text{Mor}(D_0)
  \end{array}
  $$

- two categories are associated $D_0$, $D_1$, and almost categories: $D_{(2)}$ with the set of objects $\text{Obj}(D_0)$ and the set of morphisms $\text{Obj}(D_1)$, $D_{(3)}$ with the set of objects $\text{Mor}(D_0)$ and the set of morphisms $\text{Mor}(D_1)$,

- $r, d : D_{(3)} \to D_{(2)}$ are almost functors.
Now we can define for double categories **double (category) functors** and their **morphisms**, **double subcategories**, the category $DCat$ of double categories, **equivalence** of double categories, **dual double categories** (changed direction of 1-level morphisms, i.e. $d, r$ are transposed), and so on.

**Definition 2.6** A double category functor $F : D \to D'$ is a pair $F_0 : D_0 \to D'_0, F_1 : D_1 \to D'_1$ of usual functors such that

\[
d' \circ F_1 = F_0 \circ d, \quad r' \circ F_1 = F_0 \circ r,
\]

$\forall \xi, \xi' \in \text{Obj}(D_1) \quad \varphi_{\xi,\xi'} : F_1(\xi * \xi') \overset{\sim}{\to} F_1(\xi) *' F_1(\xi')$,

$\forall A \in \text{Obj}(D_0) \quad \varphi_A : F_1(ID_A) \overset{\sim}{\to} ID_{F_0(A)}$.

**2.5 Examples of Double Categories**

Examples considered below show that double categories are sufficiently natural for mathematics.

**Example 2.1** Bicategories are the partial case of double category $D$ when the category $D_0$ is trivial, i.e. has only identical morphisms and composition of 1-level and 2-level morphisms are associative.

**Example 2.2** For each category $C$ we have the canonical double category $\text{Morph}(C)$ of morphisms. Let $C$ be a category, $T$ be the diagram $\bullet \to \bullet$, $TC$ be the category of diagrams in $C$ of type $T$, let $D_0 = C$ and $D_1 = TC$. The functor $d$ maps the diagram $f : A \to B$ into the object $A$, the functor $r$ maps this diagram into the object $B$, and so on. It is easy to see that we get a double category $D$ which is noted by $\text{Morph}(C)$. Here $\text{Obj}(D_1) = \text{Mor}(D_0)$, a 2-level morphism $f \Rightarrow g$ is a pair $(u, v)$ of morphisms $u, v \in \text{Mor}(C)$ with usual composition from the commutative diagram

\[
\begin{array}{ccc}
A & \xrightarrow{u} & A' \\
f \downarrow & & \downarrow f' \\
B & \xrightarrow{v} & B'
\end{array}
\]

**Example 2.3** Let $C$ be a category with bundle products, i.e. for all morphisms $u, v$ to $Y$ the universal square

\[
\begin{array}{ccc}
X \times_Z Y & \longrightarrow & Y \\
\downarrow & & \downarrow v \\
X & \xrightarrow{u} & Z
\end{array}
\]
exists. And let $T$ be the following diagram

$$
\bullet \leftarrow \bullet \rightarrow \bullet,
$$

$TC$ be the category of diagrams in $C$ of type $T$. Now we define the double category $D$ with $D_0 = D$ and $D_1 = TC$. Two functors

$$d, r : TC \rightarrow C,$$

where the functor $d$ maps the diagram $A \leftarrow M \rightarrow B$ into the object $A$, the functor $r$ maps this diagram into the object $B$. The composition: for two 1-level morphisms $\xi = (A \xrightarrow{\pi} M \xrightarrow{f} B) : A \Rightarrow B$ and $\xi' = (B \xrightarrow{\pi'} M' \xrightarrow{f'} C) : B \Rightarrow C$ we define their composition $\xi' \circ \xi = (A \xrightarrow{\pi \circ \pi_1} M \times_B M' \xrightarrow{f \circ f'} C)$ where the bundle product is defined by the universal diagram

$$\begin{array}{ccc}
M \times_B M' & \xrightarrow{\pi_2} & M' \\
\pi_1 \downarrow & \Downarrow & \downarrow \pi' \\
M & \xrightarrow{f} & B
\end{array}$$

A 2-level morphism is a triple $\alpha = (u, v, w) : \xi \rightarrow \xi'$ from the following commutative diagram

$$\begin{array}{ccc}
M & \xrightarrow{f} & B \\
\pi \downarrow & \nearrow v & \searrow w \\
A & \xrightarrow{\pi'} & B' \\
\nearrow u & \pi' \downarrow \\
A'
\end{array}$$

with the evident composition.

**Example 2.4** Let us consider a multiplicative (tensor) category $(C, \otimes, U, u)$. Then we have the double category with $D_1 = C$, and $D_0 = (\ast, \ast)$, e.c. a trivial category with one object and one morphism. The composition is

$$D_1 \times_{D_0} D_1 = C \times C \xrightarrow{\otimes} C.$$
Let us consider it in more details. Let $(C, \otimes, U, u)$ be a multiplicative (tensor) category with multiplication

$$\otimes : C \times C \to C : (X, Y) \mapsto X \otimes Y,$$

for the functor isomorphism of associativity

$$\varphi : \otimes \circ (id, \otimes) \to \otimes \circ (\otimes, id)$$

we write

$$\varphi_{X,Y,Z} : X \otimes (Y \otimes Z) \to (X \otimes Y) \otimes Z$$

so the pentagon is commutative

Then we have the double category $D$ with $D_0 = C$ and $D_1$ such that

$$\text{Obj}(D_1) = \{(X, x)|A, B, X \in \text{Obj}(C), \ x : X \otimes A \to B\}.$$

So, we write $\xi = (X, x) : A \Rightarrow B$ and for $\xi \in \text{Obj}(D_1)$ we denote $\xi = (X_\xi, x_\xi), d(\xi) = A_\xi, \ r(\xi) = B_\xi$. 2-level morphisms

$$D_1(\xi, \xi') = \{(f_1, f_2, f_3) \mid \text{commutative diagram} \ f_3 \otimes f_1 \downarrow \downarrow f'_2 \}$$

and $d(f_1, f_2, f_3) = f_1, \ r(f_1, f_2, f_3) = f_2$.

Composition $D_1 \times_{D_0} D_1 \to D_1$ is defined as follows

for $A \Rightarrow B \Rightarrow B'$ $\xi \circ \xi' = (A, B', X'X, x''),$ where $x''$ is the following composition

$$X' \otimes X \otimes A \xrightarrow{\varphi_{X',X,A}^{-1}} X' \otimes (X \otimes A) \xrightarrow{id_{X} \otimes x} X' \otimes B \xrightarrow{x'} B'.$$

Associativity. For $A \Rightarrow B \Rightarrow B''$ the left column gives $x_{\xi''\circ (\xi'\circ \xi)}$, the right column gives $x_{(x''\circ \xi') \circ \xi}$.
So we have isomorphism
\[(\varphi_{X''}, X, id_A, id_{B'}) : \xi'' \circ (\xi' \circ \xi) \to (\xi'' \circ \xi') \circ \xi.\]

2.5.1 Bundle of Categories

Let \(\varphi : F \to C\) be a functor and for all objects \(U \in \text{Obj} C\) and we denote by \(F_U = \varphi^{-1}(U, id_U)\) the subcategory of \(F\) with

\[
\text{Obj } F_U = \{u \in \text{Obj} F \mid \varphi(u) = U\},
\]

\[
\text{Mor } F_U = \{f \in \text{Mor } F \mid \varphi(f) = id_U\}.
\]

Let \((f : v \to u) \in \text{Mor } F\), \(\varphi(f : v \to u) = (g : V \to U)\). Then one tells that \(f\) is Descartes’s morphism, or that \(v\) is inverse image \(g^\ast(u)\) of the object \(u\), if \(\forall v' \in \text{Obj} (F_U)\) the map

\[
f_* : F_V(v', v) \to F_g(v', u) : h \mapsto f \circ h
\]

is a bijection. Here we have

\[
F_g(v, u) \overset{\text{def}}{=} \{h \in F(v, u) \mid \varphi(h) = g\}.
\]
So we have the diagram

$$
\forall v' \\
\downarrow^h \\
v \xrightarrow{f \circ h} u \\
V \xrightarrow{g} U
$$

A functor $P : \mathcal{F} \to \mathcal{C}$ is called a *bundle of categories* if inverse images allow exist and a composition two Descartes morphism is Descartes morphism too. Then $g^*$ may be transferred to functor $\mathcal{F}(U) \to \mathcal{F}(V)$, and $(g_1 \circ g_2)^*$ will be canonical isomorphic to $g_2^* \circ g_1^*$.

**Example 2.5** The projection

$$
\Pi_1 : \text{Mor}(\text{Top}) \to \text{Top} : (f : X \to Y) \mapsto X
$$

is a bundle of categories. For different structures on topological spaces it is not always truth for the category of all morphisms, but may be truth for a subcategory.

**Example 2.6** Let $\textbf{Sub}$ be a subcategory in $\text{Mor}(\text{Man})$ consists from submersions. Then projection

$$
\Pi_2 : \text{Sub} \to \text{Man} : (f : X \to Y) \mapsto Y
$$

is a bundle of categories and for each morphism $h \in \text{Man}(B', B)$ we have the functor of inverse image:

$$
h^* : \text{Sub}_B \to \text{Sub}_{B'} : (f : M \to B) \mapsto (B' \times_B M \to B').
$$

The set $\Gamma(\pi)$ of sections of an submersion $\pi : M \to B$ is the set of morphisms $\text{Sub}(id_B, \pi)$.

**Example 2.7** Let $\textbf{Mod}$ be the category of pairs $(R, M)$ where $R$ is a ring and $M$ is a left $R$-module. Let $\textbf{Rings}$ be the category of rings. Then the functor

$$
\text{Mod} \to \text{Rings} : (R, M) \mapsto R
$$

is a bundle of categories and for each morphism $h \in \text{Ring}(R', R)$ we have the functor of inverse image:

$$
h^* : \text{R-mod} \to \text{R'-mod} : M \mapsto R' \otimes_R M.
$$
2.6 Fibers of Functor Morphisms

The Grothendieck’s definition of a fiber of a functor morphism is applicable to morphisms of functors from any category to the category $\text{Sets}$ of sets. Let $F, G : C \rightarrow \text{Set}$, and $\varphi : F \rightarrow G$ be their morphism. For each object $S \in \text{Obj}(C)$ and an element $\alpha \in G(S)$ the fiber $\varphi_\alpha$ of $\varphi$ over $\alpha$ is the following functor

$$\varphi_\alpha : C/S \rightarrow \text{Sets} : f \mapsto \varphi_\alpha(f),$$

where for a morphism $f : T \rightarrow S$

$$\varphi_\alpha(f) = \{\beta \in F(T) \mid G(f) \circ \varphi_T(\beta) = \alpha\}.$$

So we have the following diagram

$$
\begin{array}{ccc}
\varphi_\alpha(f) \subset F(T) & \downarrow \varphi_T & F(S) \\
\uparrow \varphi_T & & \downarrow \varphi_S \\
G(T) & \xrightarrow{G(f)} & G(S) \ni \alpha.
\end{array}
$$

3 Multiplicative structures on categories

3.1 Concepts and state of the art

The prototype of a category is the category $\text{Sets}$ of sets and functions. The prototype of a 2-category is the category $\text{Cat}$ of small categories and functors. $\text{Cat}$ has more structure on it then a simple category because we have natural transformations between functors. This can be viewed in the following way: The extra structure implies that every morphism set $\text{Hom}(C, D)$ in $\text{Cat}$ is actually not only a set but a category itself where composition and identities in $\text{Cat}$ are compatible with this categorical structure on the Hom-sets (i.e. composition and identities are functorial with respect to the structure on the Hom-sets). A general category with this kind of extra structure is called a 2-category.

The definition of a 2-category can be put in a more general setting (which will be convenient below) by using the language of enriched categories. A category $\mathcal{C}$ is enriched over a category $\mathcal{V}$ if every Hom-set in $\mathcal{C}$ has the structure of an object in $\mathcal{V}$ and if composition and identities in $\mathcal{C}$ are compatible with this extra structure on the Hom-sets. So, a 2-category is a category enriched over $\text{Cat}$. Now, the (small) 2-categories again form a category $\text{2-Cat}$.
and a 3-category can be defined as a category enriched over \textbf{2-Cat} (indeed, \textbf{2-Cat} turns out to be a 3-category itself). In this way we can proceed iteratively to define \( n \)-categories and then \( \omega \)-categories as categories involving \( n \)-categorical structures of all levels.

A concrete recipe obtaining of monoidal (braided etc) 2-categories via Hopf categories is proposed by Crane and Frenkel [27]. Namely, that it is supposed the 2-category of module-categories over a Hopf category now plays an important role in 4-dimensional topology and TQFT. Although the theory of Hopf categories is devised, in general, by Neuchl [28], interesting examples are still missing. In particular the Hopf category, underlying the Lusztig’s canonical basis [29] of a quantized universal enveloping algebra, is not constructed yet. We propose to define it as a family of abelian categories of perverse \( \ell \)-adic sheaves equipped with some functors of multiplication and comultiplication [30]. These perverse sheaves are equivariant in the sense of Bernstein and Lunts [31].

It turns out that the notions of \( n \)-category and \( \omega \)-category are not general enough for several interesting applications. What one gets there are weak versions of these concepts (instead of weak \( n \)-category sometimes the notions bicategory, tricategory, etc. are used). Let us shortly explain what this means: In a category it does not make sense to ask for equality of objects but the appropriate notion is isomorphism. In the same way, in a 2-category we should not ask for equality of morphisms but only for equality up to an invertible 2-morphism (the morphisms between the morphisms, e.g. the natural transformations in \textbf{Cat}). Applying this to the categorical structure itself (i.e. requiring associativity and identity properties only up to natural equivalence) leads to the notion of weak 2-category (or bicategory). In the same way, we can weaken the structure of an \( n \)-category up to the \((n-1)\)-th level to obtain a weak \( n \)-category.

The point making this weakening an involved matter is that in general we need so called coherence conditions in addition to the weakened laws in order to assure that some properties, known from the strict case, hold. E.g., to assure that associativity is iteratively applicable (i.e. that we can up to a 2-isomorphism rebracket composites involving more than three factors), we need a coherence condition stating that even four factors can be rebracketed (and the other cases follow then). See the literature given above for the details.

A satisfactory version of a weak \( n \)-category for higher \( n \) and of a weak \( \omega \)-category was not available for a long time but now there are several ap-
3.2 Multiplicative Categories

**Definition 3.1** A multiplication in the category $\mathcal{C}$ is an associative functor

$$* : \mathcal{C} \times \mathcal{C} \to \mathcal{C} : (X, Y) \mapsto X * Y.$$ 

An associativity morphism for $*$ is a functor isomorphism

$$\varphi_{X,Y,Z} : X * (Y * Z) \to (X * Y) * Z$$

such that for any four objects $X, Y, Z, T$ the following diagram is commutative:

$$
\begin{array}{c}
X * (Y * (Z * T)) \\
\downarrow \ id_X * \varphi_{Y,Z,T} \\
X * ((Y * Z) * T)
\end{array}
\begin{array}{c}
\varphi_{X,Y,Z*T} \\
\varphi_{X,Y,Z*T}
\end{array}
\begin{array}{c}
(X * Y) * (Z * T) \\
\varphi_{X,Y,Z*T} \\
(X * Y) * Z * T
\end{array}
\begin{array}{c}
\uparrow \varphi_{X,Y,Z*id_T} \\
\varphi_{X,Y,Z*id_T}
\end{array}
\begin{array}{c}
X * (Y * Z) * T \\
\varphi_{X,Y,Z*T} \\
X * Y * Z * T
\end{array}
\begin{array}{c}
\uparrow \varphi_{X,Y,Z*id_T} \\
\varphi_{X,Y,Z*id_T}
\end{array}
\begin{array}{c}
X * ((Y * Z) * T) \\
\varphi_{X,Y,Z*T} \\
X * (Y * Z) * T
\end{array}
$$

An commutativity morphism for $*$ is a functor isomorphism

$$\psi_{X,Y} : X * Y \to Y * X$$

such that for any two objects $X, Y$ we have

$$\varphi_{X,Y} \circ \varphi_{Y,X} = id_{X*Y} : X * Y \to X * Y.$$ 

Morphisms associativity $\varphi$ and commutativity $\psi$ are compatible if for any three objects $X, Y, Z$ the following diagram is commutative:

$$
\begin{array}{c}
X * (Y * Z) \\
\downarrow \ id_X * \psi_{Y,Z} \\
X * (Z * Y)
\end{array}
\begin{array}{c}
\varphi_{X,Z,Y} \\
\varphi_{X,Z,Y}
\end{array}
\begin{array}{c}
(X * Y) * Z \\
\psi_{X,Y,Z} \\
Z * (X * Y)
\end{array}
\begin{array}{c}
\uparrow \varphi_{Z,X,Y} \\
\varphi_{Z,X,Y}
\end{array}
\begin{array}{c}
X * (Z * Y) \\
\varphi_{X,Z,Y} \\
X * (Z * Y)
\end{array}
\begin{array}{c}
\psi_{X,Z,Y*id_Y} \\
\psi_{X,Z,Y*id_Y}
\end{array}
\begin{array}{c}
(X * Z) * Y \\
\psi_{X,Z,Y*id_Y} \\
Z * X * Y
\end{array}
$$
A pair \((U, u)\) where \(U \in \text{Obj}(\mathcal{C})\) and an isomorphism \(u : U \to U \ast U\) is called a **unit object** for \(\mathcal{C}, \ast\) if the functor
\[
X \mapsto U \ast X : \mathcal{C} \to \mathcal{C}
\]
is equivalence of categories.

**Definition 3.2** A **multiplicative category** is a collection \((\mathcal{C}, \ast, \varphi, \psi, U, u)\).

If there are some additional structures on category, then it is usually assumed that product \(\ast\) and others elements of the collection are compatible with these structures.

### 3.3 \(\mathcal{C}\)-monoids or multiplicative objects.

**Monoidal categories and Monoids. Comonoids**

Let \(\mathcal{C} = (\mathcal{C}, \ast, \varphi, \psi, U, u)\) be a multiplicative category. An **multiplicative object** in \(\mathcal{C}\) or **\(\mathcal{C}\)-monoid** is an object \(M \in \text{Obj}(\mathcal{C})\) with multiplication \(\mu : M \ast M \to M : (m, m') \mapsto \mu(m, m')\) and an unit \(\varepsilon : U \to M\) such that the following axioms are faithful:

**1.** Associativity: the following diagram is commutative
\[
\begin{array}{ccc}
M \ast (M \ast M) & \xrightarrow{\varphi_{M,M,M}} & (M \ast M) \ast M \\
\downarrow \text{id}_M \ast \mu & & \downarrow \mu \ast \text{id}_M \\
M \ast M & \xrightarrow{\mu} & M \\
\end{array}
\]

**2.** Unit: the following diagram is commutative
\[
\begin{array}{ccc}
M & \longrightarrow & U \ast M \\
\| & & \downarrow \varepsilon \ast \text{id}_M \\
M & \xrightarrow{\mu} & M \ast M \\
\end{array}
\]

\[
\begin{array}{ccc}
M \ast U \\
\downarrow \text{id}_M \ast \varepsilon & & \downarrow \text{id}_M \ast \varepsilon \\
M \ast M & = & M \ast M
\end{array}
\]
Example 3.1 Let \( R \) be a commutative ring. The category \( R\text{-mod} \) of \( R \)-modules is a multiplicative category under the tensor product \( \otimes_R \) with the unit object is the left \( R \)-module \( R \). Multiplicative objects in the category is \( R \)-algebras with units.

Example 3.2 A small multiplicative category \( C \) is a multiplicative object of the multiplicative category \( \text{Sets//Obj}(C) \).

Multiplicative structures may be described in categories as monoids in a monoidal category.

A monoidal category \((C, \otimes, K, \varphi, \ldots)\) consists of:
\( \otimes : C \times C \rightarrow C \), \( K \in \text{ObC} \) – the unit object,
and the functor-isomorphisms:
\[
\varphi_{A,B,C} : (A \otimes B) \otimes C \rightarrow A \otimes (B \otimes C)
\]
\[
\psi_A : A \otimes K \rightarrow A, \ldots,
\]
where \( \otimes \) is symmetrical, if there exists a functor-isomorphism
\[
\theta_{A,B} : A \otimes B \rightarrow B \otimes A.
\]

A monoid in a monoidal category \((C, \otimes, K, \varphi, \ldots)\) is an object \( M \) endowed a multiplication
\[
\mu : M \otimes M \rightarrow M
\]
and the unit morphism \( \varepsilon : K \rightarrow M \) + Axioms.

A comonoid is a monoid in \((C^{op}, \otimes, K, \varphi, \ldots)\). In \( C \) we have the comultiplication
\[
\Delta : M \rightarrow M \otimes M
\]
the counit \( \eta : M \rightarrow K \) + Axioms.

An action of a monoid \( M \) on \( A \) is defined by
\[
\alpha : M \otimes A \rightarrow A
\]
+ Axioms.

A monoidal functor (a morphism of monoidal categories) of two monoidal categories is defined by \( F : (C, \otimes, K) \rightarrow (C', \otimes', K') \) if
\[
F(A \otimes B) \cong F(A) \otimes' F(B)
\]
and \( F(K) \cong K' \).
Example 3.3 A monoidal category is a monoid in the monoidal category $(\text{Cat}, \times)$ of categories with Cartesian product.

Example 3.4 The category $\text{Symm}$ with objects $[n]$ for $n = 0, 1, \ldots$ and morphisms

$$\text{Symm}([n], [m]) = \begin{cases} \emptyset, & \text{if } n \neq m, \\ \Sigma_n, & \text{if } n = m. \end{cases}$$

where $\Sigma_n$ is the group of permutations of $(1, \ldots, n)$. with the multiplication

$$*: \text{Symm} \times \text{Symm} \to \text{Symm}$$

such that $[n]*[m] \cong [n+m-1]$ with the following identification of the inputs

$$(1, \ldots, n) * (\overline{1}, \ldots, \overline{m}) = (1, \ldots, n, \overline{2}, \ldots, \overline{m})$$

which explains the action of $*$ on morphisms.

Example 3.5 Let $(\mathcal{C}, \otimes, K)$ and $(\mathcal{C}', \otimes', K')$ be two monoidal categories, $F \in \text{Ob}(\mathcal{C}')$ and $F(K) = K'$. Then for such functors $F$ on the category there is a monoidal structure and a monoid is defined by a functor morphism

$$\mu_{A,B} : F(A) \otimes' F(B) \to F(A \otimes B)$$

with natural axioms associativity and unit.

Examples 3.6–3.7 Bialgebras and Dual construction:

Algebras as monoids in $k$-bf vect, $k$-alg, Bialgebras as comonoids in $k$-alg, $k$-bialg.

Double Categories as monoids in the category of pairs of functors.

4 Categories of information transformers

4.1 Common structure of classes of information transformers

It is natural to assume that for any information transformer $a$ there are defined a couple of spaces: $\mathcal{A}$ and $\mathcal{B}$, the space of "inputs" (or input signals) and the space of "outputs" (results of measurement, transformation, processing, etc.). We will say that $a$ "acts" from $\mathcal{A}$ to $\mathcal{B}$ and denote this as
It is important to note that typically an information transformer not only transforms signals, but also introduces some “noise”. In this case it is nondeterministic and cannot be represented just by a mapping from $A$ to $B$.

It is natural to study information transformers of similar type by aggregating them into families endowed by a fairly rich algebraic structure [5,11]. Specifically, it is natural to assume that families of ITs poses the following properties:

(a) If $a: A \rightarrow B$ and $b: B \rightarrow C$ are two ITs, then their composition $b \circ a: A \rightarrow C$ is defined.

(b) This operation of composition is associative.

(c) There are certain neutral elements in these families, i.e., ITs that do not introduce any alterations. Namely, for any space $B$ there exist a corresponding IT $i_B: B \rightarrow B$ such that $i_B \circ a = a$ and $b \circ i_B = b$.

Algebraic structures of this type are called categories [6, 8].

Furthermore, we will assume, that to every pair of information transformers, acting from the same space $D$ to spaces $A$ and $B$ respectively, there corresponds a certain IT $a \ast b$ (called product of $a$ and $b$) from $D$ to $A \times B$. This IT in a certain sense “represents” both ITs $a$ and $b$ simultaneously. Specifically, ITs $a$ and $b$ can be “extracted” from $a \ast b$ by means of projections $\pi_{A,B}$ and $\nu_{A,B}$ from $A \times B$ to $A$ and $B$, respectively, i.e., $\pi_{A,B} \circ (a \ast b) = a$, $\nu_{A,B} \circ (a \ast b) = b$. Note, that typically, an IT $c$ such that $\pi_{A,B} \circ c = a$, $\nu_{A,B} \circ c = b$ is not unique, i.e., a category of ITs does not have products (in category-theoretic sense [6–9]). Thus, the notion of a category of ITs demands for an accurate formalization.

Analysis of classes of information transformers studied in [5, 10–18], gives grounds to consider these classes as categories that satisfy certain fairly general conditions.

### 4.2 Elementary axioms for categories of information transformers

In this subsection we set forward the main properties of categories of ITs. All the following study will rely exactly on these properties.

In [5, 10–18] it is shown (see also examples in section 8 below) that classes of information transformers can be considered as morphisms in certain categories. As a rule, such categories do not have products, which is a peculiar
expression of nondeterministic nature of ITs in these categories. However, it turns out that deterministic information transformers, which are usually determined in a natural way in any category of ITs, form a subcategory with products. This point makes it possible to define a “product” of objects in a category of ITs. Moreover, it provides an axiomatic way to describe an extension of the product operation from the subcategory of deterministic ITs to the whole category of ITs.

**Definition 4.1** We shall say that a category $\mathbf{C}$ is a category of information transformers if the following axioms hold:

1. There is a fixed subcategory of deterministic ITs $\mathbf{D}$ that contains all the objects of the category $\mathbf{C}$ ($\text{Ob}(\mathbf{D}) = \text{Ob}(\mathbf{C})$).

2. The classes of isomorphisms in $\mathbf{D}$ and in $\mathbf{C}$ coincide, that is, all the isomorphisms in $\mathbf{C}$ are deterministic.

3. The categories $\mathbf{D}$ and $\mathbf{C}$ have a common terminal object $\mathbf{Z}$.

4. The category $\mathbf{D}$ has pairwise products.

5. There is a specified extension of morphism product from the subcategory $\mathbf{D}$ to the whole category $\mathbf{C}$, that is, for any object $\mathbf{D}$ and for any pair of morphisms $a: \mathbf{D} \rightarrow \mathbf{A}$ and $b: \mathbf{D} \rightarrow \mathbf{B}$ in $\mathbf{C}$ there is certain information transformer $a \ast b: \mathbf{D} \rightarrow \mathbf{A} \times \mathbf{B}$ (which is also called a product of ITs $a$ and $b$) such that

$$
\pi_{\mathbf{A}, \mathbf{B}} \circ (a \ast b) = a, \\
\nu_{\mathbf{A}, \mathbf{B}} \circ (a \ast b) = b.
$$

6. Let $a: \mathbf{A} \rightarrow \mathbf{C}$ and $b: \mathbf{B} \rightarrow \mathbf{D}$ are arbitrary ITs in $\mathbf{C}$, then the IT $a \times b$ defined by Eq. (3) satisfy Eq. (5):

$$(a \times b) \circ (c \ast d) = (a \circ c) \ast (b \circ d).$$

7. Equality (7) holds not only in $\mathbf{D}$ but in $\mathbf{C}$ as well, that is, product of information transformers is “commutative up to isomorphism.”

8. Equality (9) also holds in $\mathbf{C}$. In other words, product of information transformers is “associative up to isomorphism” too.
Now let us make several comments concerning the above definition.

We stress that in the description of the extension of morphism product from the category $\mathcal{D}$ to $\mathcal{C}$ (cf. 5.) we do not require the uniqueness of an IT $c: \mathcal{D} \to \mathcal{A} \times \mathcal{B}$ that satisfy conditions (1).

Nevertheless, it is easily verified, that the equations (4) are valid for $c = a \times b$ not only in the category $\mathcal{D}$, but in $\mathcal{C}$ as well, that is,

$$\pi_{c,\mathcal{D}} \circ (a \times b) = a \circ \pi_{\mathcal{A},\mathcal{B}}, \quad \nu_{c,\mathcal{D}} \circ (a \times b) = b \circ \nu_{\mathcal{A},\mathcal{B}}.$$ 

However, the IT $c$ that satisfy the equations (4) may be not unique. Note also that in the category $\mathcal{C}$ Eq. (2) in general does not hold.

Further, note that the axiom 6 immediately implies

$$(a \times b) \circ (c \times d) = (a \circ c) \times (b \circ d).$$

Finally note that any category that has a terminal object and pairwise products can be considered as a category of ITs in which all information transformers are deterministic.

5 Category of information transformers as a monoidal category

As we have already mentioned above in a category of ITs there are certain “meaningful” operations of product for objects and for morphisms. However, these operations are not product operations in category-theoretic sense. Nevertheless, every category of ITs is a monoidal category (see, e.g., [6, 8]).

First note, that every category $\mathcal{D}$ with pairwise products and with terminal object $\mathcal{Z}$ constitutes a monoidal category $\langle \mathcal{D}, \times, \mathcal{Z}, \alpha, \lambda, \rho \rangle$, where $\times: \mathcal{D} \times \mathcal{D} \to \mathcal{D}$ is the product functor and $\alpha_{\mathcal{A},\mathcal{B},\mathcal{C}}: (\mathcal{A} \times \mathcal{B}) \times \mathcal{C} \to \mathcal{A} \times (\mathcal{B} \times \mathcal{C})$, $\lambda_\mathcal{A}: \mathcal{Z} \times \mathcal{A} \to \mathcal{A}$, and $\rho_\mathcal{A}: \mathcal{A} \times \mathcal{Z} \to \mathcal{A}$ are the obvious natural equivalences. Besides, as a category with products, the category $\mathcal{D}$ has a natural equivalence $\sigma, \sigma_{\mathcal{A},\mathcal{B}}: \mathcal{A} \times \mathcal{B} \to \mathcal{B} \times \mathcal{A}$, which interchanges components in a product.

**Definition 5.1** We will say that a category $\mathcal{C}$ is a category of information transformers over a subcategory (of deterministic ITs) $\mathcal{D}$ if the following three axioms hold.
**Axiom 1.** \( \langle C, \times, Z, \alpha, \lambda, \rho \rangle \) is a monoidal category for a certain: functor \( \times : C \times C \to C \), object \( Z \), and natural equivalences \( \alpha \), \( \lambda \) and \( \rho \).

We will refer to morphisms of the category \( C \) as *information transformers*.  

**Axiom 2.** The category \( C \) has a subcategory \( D \), such that all the objects of \( C \) are contained in \( D \), \( Z \) is a terminal object in \( D \), and the functor \( \times \) is a product functor on \( D \).  

Morphisms of the subcategory \( D \) will be called *deterministic information transformers*.  

Thus, the following properties hold in the subcategory \( D \):  
(a) There are natural transformations defined in \( D \), \( \pi_{A,B} : A \times B \to A \) and \( \nu_{A,B} : A \times B \to B \) that specify projections on components of a product.  
(b) For any deterministic Its (morphisms in \( D \)) \( a : C \to A \) and \( b : C \to B \) there exists a unique IT \( c = a \ast b : C \to A \times B \) for which \( \pi_{A,B} \circ c = a \) and \( \nu_{A,B} \circ c = b \);  
(c) \( D \) is also a monoidal category with the natural equivalences \( \alpha \), \( \lambda \) and \( \rho \) explicitly expressed through \( \pi \) and \( \nu \), i.e.,  
\[
\lambda_A \overset{\text{def}}{=} \pi_{Z,A}, \quad \rho_A \overset{\text{def}}{=} \nu_{A,Z},  
\]
\[
\alpha_{A,B,C} \overset{\text{def}}{=} (\pi_{A,B} \circ \pi_{A \times B,C}) \ast \left( (\nu_{A,B} \circ \pi_{A \times B,C}) \ast \nu_{A \times B,C} \right).  
\]
(d) There is a natural equivalence of “object transposition” \( \sigma \) defined on \( D \):  
\[
\sigma_{A,B} \overset{\text{def}}{=} \nu_{A,B} \ast \pi_{A,B} : A \times B \to B \times A.  
\]
(e) There is a “diagonal” natural transformation \( \delta \) defined on \( D \):  
\[
\delta_C \overset{\text{def}}{=} i_C \ast i_C : C \to C \times C.  
\]

Note that with the help of the “diagonal” natural transformation the product of morphisms \( a \ast b \) may be expressed through their “functorial product” \( a \times b \), i.e., \( a \ast b = (a \times b) \circ \delta_C \).

Let us stress here, that we do not require that \( \delta \) is a natural transformation on the whole category \( C \). Furthermore, typically, in many important examples of categories of ITs \( \delta \) is not a natural transformation. Such categories do not have products in category-theoretic sense. However we can extend the product operation for morphisms from the subcategory \( D \) to \( C \). Specifically, we define in \( C \):  
\[
a \ast b \overset{\text{def}}{=} (a \times b) \circ \delta_C.  
\]
Axiom 3. Natural transformations $\pi$, $\nu$ and $\sigma$ (in the category $D$) are natural transformations in the whole category $C$ as well.

Theorem 1. Definitions 4.1 and 5.1 are equivalent.

6 IT-Category as Kleisli category

6.1 Concept of distribution. Kleisli category

The two equivalent definitions presented above provide the minimal conceptual background for studying categories of ITs, e.g., for definition and analysis of informativeness, semantic informativeness, decision problems, etc. [1–5, 10–18]. However these definitions do not provide any tools for constructing categories of ITs on the basis of more elementary concepts. The concept of distribution is one of the most important and it plays a critical role in the construction of a wide spectrum of IT-categories. Its importance is connected to the observation that in many important IT-categories an information transformer $a: \mathcal{A} \rightarrow \mathcal{B}$ may be represented by a morphism from $\mathcal{A}$ to the “object of distributions” over $\mathcal{B}$. For example, a probabilistic transition distribution (an IT in the category of stochastic ITs) may be represented by a certain measurable mapping $\mathcal{A}$ to the space of distributions on $\mathcal{B}$.

Thus, we will suppose that on some fixed “base” category $D$ (category of deterministic ITs) there defined a functor $T$, which takes an object $\mathcal{A}$ to the object $T \mathcal{A}$ of “distributions” on $\mathcal{A}$. Besides, we assume that there are two natural transformations connected to this functor: $\eta: I \rightarrow T$ and $\mu: TT \rightarrow T$. Informally, $\eta_A: \mathcal{A} \rightarrow T \mathcal{A}$ takes an element of $\mathcal{A}$ to a “discrete distribution, concentrated on this element”, and $\mu_A: TT \mathcal{A} \rightarrow T \mathcal{A}$ “mixes” (averages) a distribution of distributions on $\mathcal{A}$, by transforming it to a certain distribution on $\mathcal{A}$. Besides, there are natural “coherence” conditions for $\eta$ and $\mu$:

$$\mu_A \circ T \mu_A = \mu_A \circ \mu_{T \mathcal{A}}$$

and

$$\mu_A \circ T \eta_A = i_{T \mathcal{A}} \quad \mu_A \circ \eta_{T \mathcal{A}} = i_{T \mathcal{A}}$$
that may be presented by the following commutative diagrams:

\[
\begin{array}{c}
\begin{array}{ccc}
TTT A & T \mu & T T A \\
\mu T & & \mu
\end{array} & \begin{array}{ccc}
T A & \eta T & T T A \\
T & \mu & T \eta
\end{array} & \begin{array}{ccc}
T T A & \mu & T A \\
T A & & T
\end{array}
\end{array}
\]

Commutativity of the square means that for any “third-order distribution” on \(A\) (i.e. distribution on a collection of distributions on a family of distributions on \(A\)) the result of “mixing” of distributions does not depend on the order of “mixing”. More precisely, the result of mixing over the “top” (third order, element of \(TTT A\)) distribution first and mixing the resulting second-order distribution next should give the same result as for mixing over “intermediate” (second-order, elements of \(TT A\)) distributions first and then mixing the resulting second order distribution. Commutativity of the left triangle means that mixing of a second order distribution, concentrated in one element (which is itself a distribution on \(A\)) gives this distribution. Finally, commutativity of the right triangle means if we take some distribution on \(A\), transform it to “the same” distribution of singletons and then mix the resulting second-order distribution, we will obtain the original distribution.

It is well known, that a collection \(\langle T, \eta, \mu \rangle\), satisfying the two commutative diagrams above, is called a triple (monad) \([6, 8, 23]\) on the category \(D\).

The concept of triple provides an elegant technique of constructing a category of ITs \(C\) on the basis of the category of deterministic ITs, as a Kleisli category \([6, 23]\). In this construction each morphisms \(a: A \rightarrow B\) in the category \(C\) is determined by a morphism \(a': A \rightarrow TB\) of the category \(D\). The composition \(a \circ b\) of ITs \(a: A \rightarrow B\) and \(b: B \rightarrow C\) in \(C\) is represented by the morphism

\[
(b \circ a)' \overset{\text{def}}{=} \mu_c \circ T b' \circ a'
\]

in \(D\), and any deterministic IT \(c: C \rightarrow D\) (in \(C\)) are determined by the morphism

\[
c' \overset{\text{def}}{=} \eta_B \circ c
\]

in \(D\).
6.2 Independent distribution.

Monoidal Kleisli category

The main factor in the construction of the category of ITs as a Kleisli category is equipping it with a structure of monoidal category. For this purpose we introduce a natural transformation $\gamma: \times T \to T \times, \gamma_{A,B}: TA \times TB \to T(A \times B)$, which “takes” a pair of distributions to their “independent joint distribution” (see also [35]). Then the product $c = a \ast b$ of ITs $a: D \to A$ and $b: D \to B$ (in $C$) is determined by the morphism

$$c' \overset{\text{def}}{=} \gamma_{A,B} \circ (a' \ast b')$$

in $D$. Note, that $a' \ast b'$ here exists and is uniquely defined since $D$ is a category with products.

**Theorem 2.** Suppose that $D$ is a category with pairwise products and with terminal object $Z$; $\pi$, $\nu$, $\alpha$, $\sigma$ are the corresponding natural transformations, and $\langle T, \eta, \mu \rangle$ is a triple on $D$ with $\eta_B$ monomorphic for every $B$. Then the generated Kleisli category $C$, equipped with a natural transformation $\gamma$, is a category of information transformers if and only if the following compatibility conditions of $\gamma$ with the natural transformations $\pi$, $\nu$, $\alpha$, $\sigma$, $\eta$, and $\mu$ hold:

- **$\pi$-$\gamma$ and $\nu$-$\gamma$ conditions:**
  $$T\pi_{A,B} \circ \gamma_{A,B} = \pi_{TA,TB} \quad T\nu_{A,B} \circ \gamma_{A,B} = \nu_{TA,TB}$$

- **$\sigma$-$\gamma$ condition:**
  $$T\sigma_{A,B} \circ \gamma_{A,B} = \gamma_{B,A} \circ \sigma_{TA,TB}$$

- **$\alpha$-$\gamma$ condition:**
  $$T\alpha_{A,B,C} \circ \gamma_{A \times B,C} \circ (\gamma_{A,B} \times i_C) = \gamma_{A,B \times C} \circ (i_{TA} \times \gamma_{B,C}) \circ \alpha_{TA,TB,TC}$$
\( \mu \cdot \gamma \) condition:

\[
\mu_{A \times B} \circ T \gamma_{A,B} \circ \gamma_{T,A,TB} = \gamma_{A,B} \circ (\mu_A \times \mu_B)
\]

\( \eta \cdot \gamma \) condition:

\[
\gamma_{A,B} \circ (\eta_A \times \eta_B) = \eta_{A \times B}
\]

Thus, construction of a categories of ITs is, in effect, reduced to selection of a base category \( D \), a functor \( T : D \to D \), and a natural transformation \( \gamma : \times T \to T \times \).

All these conditions have rather transparent meaning that we will try to comment below.

For better understanding we also provide the corresponding commutative diagrams in which we omit the obvious indices for the sake of readability:

\( \pi \cdot \gamma \) and \( \nu \cdot \gamma \) conditions. Marginal distributions extracted from independent joint distribution coincide with the original distributions:

\[
\begin{array}{ccc}
T \pi & & T \pi \\
\pi T & \gamma & \gamma \\
T A \times T B & \gamma & T(A \times B) \\
TB & \nu T & T \chi
\end{array}
\]

\( \sigma \cdot \gamma \) condition. Transposition of components of an independent joint distribution leads to the corresponding transformation of the joint distribution, i.e., Independent joint distribution is “invariant” with respect to transposition of its components. More precisely, we can say that the independent distribution morphism for transposed components \( \gamma_{B,A} : T B \times T A \to T(B \times A) \) is naturally isomorphic to the original morphism \( \gamma_{A,B} : T A \times T B \to T(A \times B) \). The corresponding isomorphism (of morphisms) is provided by the pair \( \langle \sigma_{T A, T B} : T \sigma_{A,B} \rangle : \)

\[
\begin{array}{ccc}
T A \times T B & \gamma & T(A \times B) \\
\sigma T & \sigma T & \sigma T \\
TB \times T A & \gamma & T(B \times A)
\end{array}
\]
\(\alpha-\gamma\) condition: Independent joint distribution for three components is "naturally invariant" with respect to the order of parentheses. More precisely, the morphisms

\[
\gamma_{A,B\times C} \circ (i_{TA} \times \gamma_{B,C}) : T(A \times (TB \times TC)) \rightarrow T(A \times (B \times C))
\]

and

\[
\gamma_{A\times B,C} \circ (\gamma_{A,B} \times i_{TC}) : (T(A \times TB) \times TC) \rightarrow T((A \times B) \times C)
\]

(that take independent joint distributions for three components with different order of parentheses) are naturally isomorphic via \(\langle \alpha_{TA,TB,TC}, T\alpha_{A,B,C} \rangle\):

\[
\begin{array}{ccc}
(TA \times TB) \times TC & \xrightarrow{\gamma \times T} & T(A \times B) \times TC & \xrightarrow{\gamma} & T((A \times B) \times C) \\
\downarrow \alpha_T & & & \downarrow & \downarrow T\alpha \\
TA \times (TB \times TC) & \xrightarrow{T \times \gamma} & T(A \times (T(B \times C)) & \xrightarrow{\gamma} & T(A \times (B \times C))
\end{array}
\]

\(\mu-\gamma\) condition. Independent joint distribution for results of mixing of two second-order distributions may also be obtained by mixing the corresponding second-order independent distributions:

\[
TTA \times TT\!B \xrightarrow{\gamma_T} T(TA \times TB) \xrightarrow{T\gamma} TT(A \times B)
\]

\[
\downarrow \mu \times \mu \quad \quad \quad \quad \downarrow \mu
\]

\[
TA \times TB \xrightarrow{\gamma} T(A \times B)
\]

\(\eta-\gamma\) condition: Independent joint distribution for two "singleton" distributions is just the corresponding "singleton" distribution on a product space:

\[
\begin{array}{ccc}
A \times B & \xrightarrow{\eta} & T(A \times B) \\
\eta \times \eta & \downarrow & \downarrow \eta \\
TA \times TB & \xrightarrow{\gamma} & T(A \times B)
\end{array}
\]
7 Informativeness of information transformers

7.1 Accuracy relation

In order to define informativeness relation we will need to introduce first the following auxiliary notion.

**Definition 7.1** We will say that $\triangleright$ is an accuracy relation on an IT-category $\mathcal{C}$ if for any pair of objects $\mathcal{A}$ and $\mathcal{B}$ in $\mathcal{C}$ the set $\mathcal{C}(\mathcal{A}, \mathcal{B})$ of all ITs from $\mathcal{A}$ to $\mathcal{B}$ is equipped with a partial order $\triangleright$ that satisfies the following monotonicity conditions:

\[ a \triangleright a', \ b \triangleright b' \implies a \circ b \triangleright a' \circ b', \]
\[ a \triangleright a', \ b \triangleright b' \implies a \ast b \triangleright a' \ast b'. \]

Thus, the composition and the product are monotonous with respect to the partial order $\triangleright$. For a pair of ITs $a, b \in \mathcal{C}(\mathcal{A}, \mathcal{B})$ we shall say that $a$ is more accurate than $b$ whenever $a \triangleright b$.

It obviously follows from the very definition of the operation $\times$ (3) and from the monotonicity conditions that the operation $\times$ is monotone as well:

\[ a \triangleright a', \ b \triangleright b' \implies a \times b \triangleright a' \times b'. \]

It is clear that for any IT-category there exists at least a “trivial variant” of the partial order $\triangleright$, namely, one can choose an equality relation for $\triangleright$, that is, one can put $a \triangleright b \overset{\text{def}}{=} a = b$. However, many categories of ITs (for example, multivalued and fuzzy ITs) provide a “natural” choice of the accuracy relation, which is different from the equality relation.

7.2 Definition of informativeness relation

Suppose $a: \mathcal{D} \rightarrow \mathcal{A}$ and $b: \mathcal{D} \rightarrow \mathcal{B}$ are two information transformers with a common source $\mathcal{D}$. Assume that there exists an IT $c: \mathcal{A} \rightarrow \mathcal{B}$ such that $c \circ a = b$. Then any information that can be obtained from $b$ can be obtained from $a$ as well (by attaching the IT $c$ next to $a$). Thus, it is natural to consider the information transformer $a$ as being more informative than the IT $b$ and also more informative than any IT less accurate than $b$.

Now we give the formal definition of the informativeness relation in the category of information transformers.
**Definition 7.2** We shall say that an information transformer \( a \) is more informative (better) than \( b \) if there exists an information transformer \( c \) such that \( c \circ a \succ b \), that is,

\[
a \succ b \iff \exists c \; c \circ a \succ b.
\]

It is easily verified that the informativeness relation \( \succ \) is a preorder on the class of information transformers in \( C \). This preorder \( \succ \) induces an equivalence relation \( \sim \) in the following way:

\[
a \sim b \iff a \succ b \; \& \; b \succ a.
\]

Obviously, the relation “more informative” extends the relation “more accurate,” that is,

\[
a \succ b \implies a \succ b.
\]

### 7.3 Main properties of informativeness

It can be easily verified that the informativeness relation \( \succ \) satisfies the following natural properties.

**Lemma 1.** Consider all information transformers with a fixed source \( D \).

(a) The identity information transformer \( i_D \) is the most informative and the terminal information transformer \( z_D \) is the least informative:

\[
\forall a \; i_D \succ a \succ z_D.
\]

(b) Any information transformer \( a: D \to B \times C \) is more informative than its parts \( \pi_{B,C} \circ a \) and \( \nu_{B,C} \circ a \).

(c) The product \( a \ast b \) is more informative than its components

\[
a \ast b \succ a, b.
\]

Furthermore, the informativeness relation is compatible with the composition and the product operations.

**Lemma 2.**

(a) If \( a \succ b \), then \( a \circ c \succ b \circ c \).

(b) If \( a \succ b \) and \( c \succ e \), then \( a \ast c \succ b \ast e \).
7.4 Structure of the family of informativeness equivalence classes

Let \(a\) be some information transformer. We shall denote by \([a]\) the equivalence (with respect to informativeness) class of \(a\). We shall also use boldface for equivalence classes, that is, \(a \in a\) is equivalent to \(a = [a]\).

**Theorem 3.** Let \(\mathfrak{J}(\mathcal{D})\) be the family of informativeness equivalence classes for the class of all information transformers with a fixed domain \(\mathcal{D}\). The family \(\mathfrak{J}(\mathcal{D})\) forms a partial ordered Abelian monoid \(\langle \mathfrak{J}(\mathcal{D}), \succeq, \ast, 0 \rangle\) with the smallest element \(0\) and the largest element \(1\), where

\[
[a] \succeq [b] \iff a \succeq b, \quad [a] \ast [b] \equiv [a \ast b], \quad 0 \equiv [\varepsilon_{\mathcal{D}}], \quad 1 \equiv [\iota_{\mathcal{D}}].
\]

Moreover, the following properties hold:

(a) \(0 \ast a = a\),

(b) \(1 \ast a = 1\),

(c) \(0 \preceq a \preceq 1\),

(d) \(a \ast b \succeq a, b\),

(e) \((a \succeq b) \& (c \succeq e) \implies a \ast c \succeq b \ast e\).

8 Informativeness and synthesis of optimal information transformers

In this section, we consider an alternative (with respect to the above) approach to informativeness comparison. This approach is based on treating information transformers as data sources for decision-making problems.

8.1 Decision-making problems in categories of ITs

Results of observations, obtained on real sources of information (e.g. indirect measurements) are as a rule unsuitable for straightforward interpretation. Typically it is assumed that observations suitable for interpretation are those into a certain object \(\mathcal{U}\) which in what follows will be called object of interpretations or object of decisions.
By an *interpretable* information transformer for signals from an object $\mathcal{D}$ we mean any information transformer $a: \mathcal{D} \to \mathcal{U}$.

It is usually thought that some interpretable information transformers are more suitable for interpretation (of obtained results) than others. Namely, on a set $\mathcal{C}(\mathcal{D}, \mathcal{U})$ of information transformers from $\mathcal{D}$ to $\mathcal{U}$, one defines some preorder relation $\gg$, which specifies the relative quality of various interpretable information transformers. Typically the relation $\gg$ is predetermined by the specific formulation of a problem of optimal information transformer synthesis (that is, decision-making problem).

We shall say that an abstract *decision-making problem* is determined by a triple $\langle \mathcal{D}, \mathcal{U}, \gg \rangle$, where $\mathcal{D}$ is an object of studied (input) signals, $\mathcal{U}$ is an object of decisions (or interpretations), and $\gg$ is a preorder on the set $\mathcal{C}(\mathcal{D}, \mathcal{U})$.

We shall call a preorder $\gg$ *monotone* if for any $a, b \in \mathcal{C}(\mathcal{D}, \mathcal{U})$

$$a \gg b \Rightarrow a \gg b,$$

that is, more accurate IT provides better quality of interpretation.

For a given information transformer $a: \mathcal{D} \to \mathcal{A}$ we shall also say that an IT $b$ *reduces* $a$ to an interpretable information transformer if $b \circ a: \mathcal{D} \to \mathcal{U}$, that is, if $b: \mathcal{A} \to \mathcal{U}$. Such an information transformer $b$ will be called a *decision strategy*.

The set of all interpretable information transformers obtainable on the basis of $a: \mathcal{D} \to \mathcal{A}$ will be denoted $\mathcal{U}_a \subseteq \mathcal{C}(\mathcal{D}, \mathcal{U})$:

$$\mathcal{U}_a \overset{\text{def}}{=} \{b \circ a \mid b: \mathcal{A} \to \mathcal{U}\}.$$

We shall call a decision strategy $r: \mathcal{A} \to \mathcal{U}$ *optimal* (for the IT $a$ with respect to the problem $\langle \mathcal{D}, \mathcal{U}, \gg \rangle$) if the IT $r \circ a$ is a maximal element in $\mathcal{U}_a$ with respect to $\gg$. Thus, a decision-making problem for a given information transformer $a$ is stated as the problem of constructing optimal decision strategies.

### 8.2 Semantical informativeness

The relation $\gg$ induces a preorder relation $\sqsupseteq$ on a class of information transformers operating from $\mathcal{D}$ in the following way.
Assume that $a$ and $b$ are information transformers with the source $\mathcal{D}$, that is, $a: \mathcal{D} \to \mathcal{A}$, $b: \mathcal{D} \to \mathcal{B}$. By definition, put

$$a \sqsupseteq b \iff \forall b': \mathcal{B} \to \mathcal{U} \exists a': \mathcal{A} \to \mathcal{U} \quad a' \circ a \gg b' \circ b.$$ 

In other words, $a \sqsupseteq b$ if for every interpretable information transformer $d$ derived from $b$ there exists an interpretable information transformer $c$ derived from $a$ such that $c \gg d$, that is,

$$a \sqsupseteq b \iff \forall d \in \mathcal{U}_b \exists c \in \mathcal{U}_a \quad c \gg d.$$ 

It can easily be checked that the relation $\sqsubseteq$ is a preorder relation.

It is natural to expect that if one information transformer is more informative than the other, then the former will be better than the latter in any context. In other words, for any preorder $\gg$ on the set of interpretable information transformers the induced preorder $\sqsubseteq$ is dominated by the informativeness relation $\gg$ (that is, $\sqsubseteq$ is weaker than $\gg$). The converse is also true.

**Definition 8.1** We shall say that an information transformer $a$ is semantically more informative than $b$ if for any interpretation object $\mathcal{U}$ and for any preorder $\gg$ (on the set of interpretable information transformers) $a \sqsupseteq b$ for the induced preorder $\sqsubseteq$.

The following theorem is in some sense a “completeness” theorem, which establishes a relation between “structure” ($b$ can be “derived” from $a$) and “semantics” ($a$ is uniformly better then $b$ in decision-making problems).

**Theorem 4.**

For any information transformers $a$ and $b$ with a common source $\mathcal{D}$, information transformer $a$ is more informative than $b$ if and only if $a$ is semantically more informative than $b$.

Let us remark that the above proof relies heavily on the extreme extent of the class of decision problems involved. This makes it possible to select for any given pair of ITs $a, b$ an appropriate decision-making problem $(\mathcal{D}, \mathcal{U}_b, \gg_b)$ in which the interpretation object $\mathcal{U}_b$ and the preorder $\gg_b$ depend on the IT $b$. However, in some cases it is possible to point out a concrete (universal) decision-making problem such that

$$a \gg b \iff a \sqsupseteq b.$$
Theorem 5.
Assume that for a given object \( D \) there exists an object \( \tilde{D} \) such that for every information transformer acting from \( D \) there exists an equivalent (with respect to informativeness) IT acting from \( D \) to \( \tilde{D} \), that is,
\[
\forall B \ \forall b: D \to B \ \exists b': D \to \tilde{D} \ \ b \sim b'.
\]
Let us choose the decision object \( U \) \( \overset{\text{def}}{=} \tilde{D} \) and the preorder \( \gg \), defined by
\[
c \gg d \ \overset{\text{def}}{\iff} \ c \bowtie d.
\]
Then \( a \gg b \) if and only if \( a \supseteq b \).

Note that in general case an optimal decision strategy (if exists) can be nondeterministic. However, in many cases it is sufficient to search optimal strategies among deterministic ITs. Indeed, in some categories of information transformers the relation of “accuracy” satisfies the following condition: every IT is dominated by some deterministic IT, that is, for every IT there exists a more accurate deterministic IT.

Proposition 1.
Assume that \( \langle D, U, \gg \rangle \) is a monotone decision-making problem in a category of ITs \( C \). Assume also that the following condition holds:
\[
\forall c \in \text{Ar}(C) \ \exists d \in \text{Ar}(D) \ \ d \gg c.
\]
Then for any IT \( a: D \to R \) and for any decision strategy \( r: R \to U \) there exists a deterministic strategy \( r_0: R \to U \) such that \( r_0 \circ a \gg r \circ a \).

9 Decision-making problems with a prior information

In this section we formulate in terms of categories of information transformers an analogy for the classical problem of optimal decision strategy construction for decision problems with a prior information (or information a priori). We also prove a counterpart of the Bayesian principle from the theory of statistical games [24, 36]. Like its statistical prototype it reduces the problem of constructing an optimal decision strategy to a much simpler problem of finding an optimal decision for a posterior information (or information a posteriori).
First we define in terms of categories of information transformers some necessary concepts, namely, concepts of distribution, conditional information transformer, decision problem with a prior information, and others.

9.1 Distributions in categories of ITs

We shall say that a distribution on an object \( A \) (in some fixed category of ITs \( C \)) is any IT \( f: Z \to A \), where \( Z \) is the terminal object in \( C \).

The concept of distribution corresponds to the general concept of an element of some object in a category, namely, a morphism from the terminal object (see, e.g., [9]).

Any distribution of the form \( h: Z \to A \times B \) will be called a joint distribution on \( A \) and \( B \). The projections \( \pi_{A,B} \) and \( \nu_{A,B} \) on the components \( A \) and \( B \) respectively, “extract” marginal distributions \( f \) and \( g \) of the joint distribution \( h \), that is,

\[
\begin{align*}
f &= \pi_{A,B} \circ h: Z \to A, \\
g &= \nu_{A,B} \circ h: Z \to B.
\end{align*}
\]

We say that the components of a joint distribution \( h: Z \to A \times B \) are independent whenever this joint distribution is completely determined by its marginal distributions, that is,

\[
h = (\pi_{A,B} \circ h) \ast (\nu_{A,B} \circ h).
\]

Let \( f \) be an arbitrary distribution on \( A \) and let \( a: A \to B \) be some information transformer. Then the distribution \( g = a \circ f \) in some sense “contains an information about \( f \).” This concept can be expressed precisely of one consider the joint distribution generated by the distribution \( f \) and the IT \( a \):

\[
h: Z \to A \times B, \quad h = (i_A \ast a) \circ f.
\]

Note, that the marginal distributions for \( h \) coincide with \( f \) and \( g \), respectively. Indeed,

\[
\begin{align*}
\pi_{A,B} \circ h &= \pi_{A,B} \circ (i_A \ast a) \circ f = i_A \circ f = f, \\
\nu_{A,B} \circ h &= \nu_{A,B} \circ (i_A \ast a) \circ f = a \circ f = g.
\end{align*}
\]

Let \( h \) be a joint distribution on \( A \times B \). We shall say that \( a: A \to B \) is a conditional IT for \( h \) with respect to \( A \) whenever \( h \) is generated by the marginal distribution \( \pi_{A,B} \circ h \) and the IT \( a \), that is,

\[
h = (i_A \ast a) \circ \pi_{A,B} \circ h.
\]
Similarly, an IT \( b: B \to A \) such that

\[
h = (b \star i_B) \circ \nu_{A, B} \circ h
\]

will be called a conditional IT for \( h \) with respect to \( B \).

9.2 Bayesian decision-making problems

Suppose that, like in Section 4, there are fixed two objects \( D \) and \( U \) in some category of ITs, namely, the object of signals and the object of decisions, respectively. In a decision-making problem with a prior distribution \( f \) on \( D \) one fixes some preorder \( \gg_f \) on the set of joint distributions on \( D \times U \) for which \( D \)-marginal distribution coincides with \( f \).

Informally, any joint distribution \( h \) on \( D \times U \) of this kind can be considered as a joint distribution of a studied signal (with the distribution \( f = \pi_{D,U} \circ h \) on \( D \)) and a decision (with the distribution \( g = \nu_{D,U} \circ h \) on \( U \)). The preorder \( \gg_f \) determines how good is the “correlation” between studied signals and decisions.

Formally, an abstract decision problem with a prior information is determined by a quadruple \( \langle D, U, f, \gg_f \rangle \), where \( D \) is an object of studied signals, \( U \) is an object of decisions (or interpretations), \( f: Z \to D \) is a prior distribution (or distribution a priori), and \( \gg_f \) is a preorder on the set of ITs \( h: Z \to D \times U \) that satisfy the condition \( \pi_{D,U} \circ h = f \).

Furthermore, suppose that there is a fixed IT \( a: D \to R \) (which determines a measurement; \( R \) can be called an object of observations). An IT \( r: R \to U \) is called optimal (for the IT \( a \) with respect to \( \gg_f \)) if the distribution \( (i \star r \circ a) \circ f \) is a maximal element with respect to \( \gg_f \). The set of all optimal information transformers is denoted \( \text{Opt}_f(a \circ f) \).

**Theorem 6** (Bayesian principle).

Let \( f \) be a given prior distribution on \( D \), let \( a: D \to R \) be a fixed IT; and let \( b: R \to D \) be a conditional information transformer for \( (i \star a) \circ f \) with respect to \( R \). Then the set of optimal ITs \( r: R \to U \), namely, the set of optimal decision strategies for \( f \) over \( a \circ f \) coincides with the set of optimal decision strategies for \( b \circ g \) over \( g \), where \( g = a \circ f \):

\[
\text{Opt}_f(a \circ f) = \text{Opt}_{b \circ g}(g).
\]

In a wide class of decision problems (e.g., in linear estimation problems) an optimal IT \( r \) happens to be deterministic and is specified by the “deterministic part” of the IT \( b \).
For many categories of information transformers (for example, stochastic, multivalued, and fuzzy ITs [13, 15, 24]) an optimal decision strategy \( r \) can be constructed “pointwise” according to the following scheme. For the given “result of observation” \( y \in \mathcal{R} \) consider the conditional (posterior) distribution \( b(y) \) for \( f \) under a fixed \( g = y \), and put

\[
r(y) \overset{\text{def}}{=} d_{b(y)},
\]

where \( d_{b(y)} \) is an optimal decision with respect to the posterior distribution \( b(y) \).

10 Examples of categories of information transformers

In this section we present several examples of different classes of information transformers. The major difference between them is the way of representing uncertainty. In each case (except the category stochastic linear ITs, which cannot be constructed as a Kleisli category, but is a subcategory of one) we will mention the corresponding: base category \( \mathcal{D} \), functor \( T \), and natural transformation \( \gamma \). “Elementary” definitions for these categories may be found in [14, 21, 22].

10.1 Stochastic ITs

Let \( \mathcal{D} = \text{Meas} \), the category of measurable spaces and measurable maps, \( T \) \( \mathcal{A} \) is the space of all probability measures on \( \mathcal{A} \), (details may be found in [37]) and \( \gamma_{A,B} \) takes a pair of distributions \( \mathcal{P}, \mathcal{Q} \) to their product \( \mathcal{P} \otimes \mathcal{Q} \), a distribution on \( A \times B \).

The category of stochastic information transformers \( \text{ST} \) consists of measurable spaces (as objects) and transition probability functions (as morphisms, that is, information transformers) [3, 4, 37]. Note that a classical statistical experiment (namely, a parametrized family of probability measures), a statistics (namely, a measurable function of a sample of observations), and a decision strategy (possibly, nondeterministic) can be represented by appropriate transition probability functions. Thus, all the above concepts fit in well with this scheme.
Suppose $A = \langle \Omega_A, \mathcal{S}_A \rangle$ and $B = \langle \Omega_B, \mathcal{S}_B \rangle$ are two measurable spaces. A stochastic information transformer $a: A \rightarrow B$ is determined by a real-valued function (transition probability function $P_a(\omega, B)$) of two arguments $\omega \in \Omega_A$, $B \in \mathcal{S}_B$ that satisfy the following conditions:

(a) Given a fixed event $B \in \mathcal{S}_B$, the map $P_a(\cdot, B)$ is a measurable function on $\Omega_A$.

(b) Given a fixed elementary event $\omega \in \Omega_A$, the map $P_a(\omega, \cdot)$ is a probability measure on $\langle \Omega_B, \mathcal{S}_B \rangle$.

For a given stochastic information transformers $a: A \rightarrow B$ and $b: B \rightarrow C$ their composition $b \circ a$ in the category $\text{ST}$ corresponds to the transition probability function (see [3,37])

$$P_{b \circ a}(\omega, C) = \int_{\Omega_B} P_b(\omega', C) P_a(\omega, d\omega') \quad \forall \omega \in \Omega_A, \forall C \in \mathcal{S}_C.$$ 

The subcategory of deterministic ITs is actually a category $\text{Meas}$ of measurable spaces and measurable maps. To every measurable map $\varphi: A \rightarrow B$ there corresponds the transition probability function

$$P_\varphi(\omega, B) = \begin{cases} 1, & \text{if } \varphi(\omega) \in B, \\ 0, & \text{if } \varphi(\omega) \notin B; \end{cases} \quad \forall \omega \in \Omega_A, \forall B \in \mathcal{S}_B.$$ 

The category $\text{Meas}$ has products, namely, the product of measurable spaces $A$ and $B$ in $\text{Meas}$ is $\langle A \times B, \pi_{A,B}, \nu_{A,B} \rangle$, where

$$A \times B \equiv \langle \Omega_A \times \Omega_B, \mathcal{S}_A \otimes \mathcal{S}_B \rangle,$$

$\pi_{A,B}$ and $\nu_{A,B}$ are the projections from the Cartesian product $\Omega_A \times \Omega_B$ onto its components $\Omega_A$ and $\Omega_B$ respectively, and $\mathcal{S}_A \otimes \mathcal{S}_B$ is the product of $\sigma$-algebras $\mathcal{S}_A$ and $\mathcal{S}_B$.

For a given pair of ITs $a: D \rightarrow A$ and $b: D \rightarrow B$ with a common source we define their product $a*b: D \rightarrow A \times B$ so that for every $\omega \in \Omega_D$ the probability distribution $P_{a*b}(\omega, \cdot)$ on $A \times B$ is the product $\otimes$ of the distributions $P_a(\omega, \cdot)$ and $P_b(\omega, \cdot)$, that is,

$$P_{a*b}(\omega, \cdot) \equiv P_a(\omega, \cdot) \otimes P_b(\omega, \cdot) \quad \forall \omega \in \Omega_D.$$
In other words (see, for example, [38]), the distribution $P_{ab}$ is completely determined by the following condition:

$$P_{ab}(\omega, A \times B) \overset{\text{def}}{=} P_a(\omega, A) P_b(\omega, B) \quad \forall \omega \in \Omega, \quad \forall A \in \mathcal{S}_A, \quad \forall B \in \mathcal{S}_B.$$  

The only obvious choice for the accuracy relation in the category of stochastic ITs seems to be the equality relation.

Now let us demonstrate that the basic concepts of mathematical statistics are adequately described in terms of this IT-category. Namely, we shall verify that the concepts of distribution, conditional distribution, etc. (introduced above in terms of IT-categories), in the category of stochastic ITs lead to the corresponding classical concepts.

Indeed, any probability distribution $Q$ on a given measurable space $A = \langle \Omega_A, \mathcal{S}_A \rangle$ is uniquely determined by the morphism $f: Z \to A$ from the terminal object $Z = \langle \{0\}, \{\emptyset, \{0\}\} \rangle$ (a one-point measurable space) such that

$$P_f(0, A) = Q(A) \quad \forall A \in \mathcal{S}_A.$$  

In what follows we shall omit the first argument in $P_f(0, A)$ and write just $P_f(A)$ instead.

A statistical experiment is described by a family of probability measures $Q_\theta$ on some measurable space $B$. This family is usually parametrized by elements of a certain set $\Omega_A$. Sometimes (especially when statistical problems with a prior information are studied) it is additionally assumed that the set $\Omega_A$ is equipped by some $\sigma$-algebra $\mathcal{S}_A$ and that $Q_\theta(B)$ is a measurable function of $\theta \in \Omega_A$ for all $B \in \mathcal{S}_B$ (and thus, $Q_\theta(B)$ is a transition probability function [39]). Therefore, such statistical experiment is determined by the stochastic information transformer $a: A \to B$, where

$$P_a(\theta, B) = Q_\theta(B) \quad \forall \theta \in \Omega_A, \quad \forall B \in \mathcal{S}_B.$$  

In the case when no $\sigma$-algebra on the set $\Omega_A$ is specified, one can put $\mathcal{S}_A = \mathcal{P} (\Omega_A)$, that is, the $\sigma$-algebra of all the subsets of the set $\Omega_A$. It is clear that in this case the function $P_a(\theta, B) = Q_\theta(B)$ is a measurable function of $\theta \in \Omega_A$ for every fixed $B \in \mathcal{S}_B$ and thus (being a transition probability function), is described by a stochastic IT $a: A \to B$.

Note also, that any statistic, being a measurable function, is represented by a certain deterministic IT. Decision strategies also correspond to deterministic ITs. At the same time, nondeterministic (mixed) decision strategies
are adequately represented by stochastic information transformers of general kind.

Now, let $f$ be some fixed distribution on $\mathcal{A}$ and let $a: \mathcal{A} \to \mathcal{B}$ be some IT. The joint distribution $h$ on $\mathcal{A} \times \mathcal{B}$, generated by $f$ and $a$ (from the IT-categorical point of view, see Section 7) is

$$h = (i \ast a) \circ f.$$  

It means that for every set $A \times B$, where $A \in \Omega_A$ and $B \in \Omega_B$,

$$P_h(A \times B) = \int_{\Omega_A} P_{i \ast a}(\omega, A \times B) P_f(d\omega) \quad = \int_{\Omega_A} P_i(\omega, A) P_a(\omega, B) P_f(d\omega) \quad = \int_A P_a(\omega, B) P_f(d\omega).$$

Thus we come to the well known classical expression for the generated joint distribution (see, for example, [39]).

Now assume that $P_f$ is considered as some probability prior distribution (or distribution a priori) on $\mathcal{A}$. Then for a given transition probability function $P_a$, a posterior (or conditional) distribution $P_b(\omega', \cdot)$ on $\mathcal{A}$ for a fixed $\omega' \in \Omega_B$ is determined, accordingly to [39] by a transition probability function $P_b(\omega', A)$, $\omega' \in \Omega_B$, $A \in \mathcal{S}_A$ such that

$$P_h(A \times B) = \int_B P_b(\omega', A) P_g(d\omega') \quad \forall A \in \mathcal{S}_A, \quad \forall B \in \mathcal{S}_B,$$

where

$$P_g(B) = \int_{\Omega_A} P_a(\omega, B) P_f(d\omega) \quad \forall B \in \mathcal{S}_B.$$  

It is easily verified that in terms of ITs the above expressions have the following forms:

$$h = (b \ast i) \circ g,$$

where

$$g = a \circ f.$$
This shows, that the classical concept of conditional distribution is adequately described by the concept of conditional IT in terms of categories of information transformers.

### 10.2 Linear stochastic ITs with additive noise

As we will see this category of ITs cannot be constructed as a Kleisli category, but is a subcategory the category of stochastic ITs, examined above.

Suppose $\mathcal{D}$ and $\mathcal{R}$ are arbitrary finite-dimensional Euclidean spaces. We shall say that a linear information transformer [11, 12] (measurement model [40]) $a$ acting from $\mathcal{D}$ to $\mathcal{R}$

$$a : \mathcal{D} \to \mathcal{R},$$

is determined by a pair

$$\langle A_a, \Sigma_a \rangle, \quad A_a : \mathcal{D} \to \mathcal{R}, \quad \Sigma_a : \mathcal{R} \to \mathcal{R}, \quad \Sigma_a \geq 0,$$

where $A_a$ and $\Sigma_a$ are linear maps.

Such pair $\langle A_a, \Sigma_a \rangle$ represents a statistical experiment of the form [40]

$$y = A_a x + \nu, \quad x \in \mathcal{D}, \quad y \in \mathcal{R},$$

where $\nu$ is a random vector in $\mathcal{R}$ with the zero mean and the correlation operator $\Sigma_a$.

The composition of two linear ITs $\langle A_a, \Sigma_a \rangle : \mathcal{D} \to \mathcal{A}$ and $\langle A_b, \Sigma_b \rangle : \mathcal{A} \to \mathcal{B}$ is defined by

$$\langle A_b, \Sigma_b \rangle \circ \langle A_a, \Sigma_a \rangle \overset{\text{def}}{=} \langle A_b A_a, \Sigma_b + A_b \Sigma_a A_b^* \rangle.$$

The composition corresponds to the consecutive connection of information transformers that have independent random errors.

The product of two information transformers

$$\langle A_a, \Sigma_a \rangle : \mathcal{D} \to \mathcal{A}, \quad \langle A_b, \Sigma_b \rangle : \mathcal{D} \to \mathcal{B}$$

is defined by:

$$\langle A_a, \Sigma_a \rangle \ast \langle A_b, \Sigma_b \rangle \overset{\text{def}}{=} \langle A_{a+b}, \Sigma_{a+b} \rangle : \mathcal{D} \to \mathcal{A} \times \mathcal{B},$$
where
\[ A_{a^*b} : D \to A \times B, \quad A_{a^*b}x \overset{\text{def}}{=} \langle A_ax, A_bx \rangle, \]
\[ \Sigma_{a^*b} : A \times B \to A \times B, \quad \Sigma_{a^*b} \langle x, y \rangle \overset{\text{def}}{=} \langle \Sigma_ax, \Sigma_by \rangle. \]

This construction gives us the category \( \text{SLT} \) with the subcategory of deterministic ITs is (isomorphic to) the category of Euclidean spaces and linear maps. In this case a linear map \( A : D \to R \) corresponds to the IT \( \langle A, 0 \rangle : D \to R \).

As we have already mentioned this category of ITs cannot be constructed as a Kleisli category over the category of finite dimensional Euclidean spaces. Indeed we can not define a “space of distributions” on some space \( A \) as a finite dimensional linear space, and thus, can not define functor \( T \) in the category of finite dimensional Euclidean spaces. However, \( \text{SLT} \) may be considered as a subcategory the category of stochastic ITs \( \text{ST} \), examined above. Indeed, each Euclidean space may be considered as a measurable space endowed with Borel \( \sigma \)-algebra. Finally, we may consider an IT \( a = \langle A_a, \Sigma_a \rangle : D \to R \) (in \( \text{SLT} \)) as the transition probability, that takes an element \( x \in D \) to the normal distribution \( N(A_0x, \Sigma_a) \) with the mean value \( A_0x \) and the correlation operator \( \Sigma_a \). Routine verification shows, that the composition and product operations are preserved under such inclusion of \( \text{SLT} \) into \( \text{ST} \).

In addition to the trivial relation of accuracy (which coincides with the equality relation) one can define the accuracy relation in the following way:

\[ \langle A_a, \Sigma_a \rangle \succ \langle A_b, \Sigma_b \rangle \overset{\text{def}}{\iff} A_a = A_b, \Sigma_a \leq \Sigma_b. \]

However, it can be proved that the informativeness relations corresponding these different accuracy preorders, actually coincide.

In the category of linear information transformers every equivalence class \([a]\) corresponds to a pair \( \langle Q, S \rangle \), where \( Q \subseteq D \) is an Euclidean subspace and \( S : Q \to Q \) is nonnegative definite operator, that is, \( S \geq 0 \). In these terms

\[ \langle Q_1, S_1 \rangle \geq \langle Q_2, S_2 \rangle \overset{\text{def}}{\iff} Q_1 \supseteq Q_2, \quad S_1 \upharpoonright Q_2 \leq S_2. \]

Here \( S_1 \upharpoonright Q_2 \) (the restriction of \( S_1 \) on \( Q_2 \)) is defined by the expression \( S_1 \upharpoonright Q_2 \overset{\text{def}}{=} P_2I_1S_1P_1I_2 \), where \( I_j : Q_j \to D \) is the subspace inclusion, and \( P_j : D \to Q_j \) is the orthogonal projection (cf. [11, 40]).

Note also that in the category of linear information transformers every IT is dominated (in the sense of the preorder relation \( \succ \)) by a deterministic IT.
Hence, according to Proposition 2, in any monotone decision-making problem without loss of quality one can search optimal decision strategies in the class of deterministic ITs.

It is shown in [12], that in the category of linear ITs for any joint distribution there always exist conditional distributions. Thus in problems with a prior information one can apply Bayesian principle. Its direct proof in the category of linear ITs as well as the explicit expression for conditional information transformers can be found in [12].

10.3 The category of sets as a category of ITs

As a trivial example of IT-category we consider the category of sets Set, whose objects are sets and morphisms are maps. This category has products, hence all the ITs are deterministic. In fact this category is trivially a Kleisli category with identity functor as functor $T$.

It is not hard to prove that for a given set $D$, the class of equivalent informativeness for an IT $a$ with the set $D$ being its domain, is completely determined by the following equivalence relation $\approx_a$ on $D$:

$$x \approx_a y \iff ax = ay \quad \forall x, y \in D.$$ 

Furthermore, $a \succ b$ if and only if the equivalence relation $\approx_a$ is finer than $\approx_b$, that is,

$$a \succ b \iff \forall x, y \in D \quad (x \approx_a y \implies x \approx_b y).$$

Thus, the partially ordered monoid of equivalence classes for ITs with the source $D$, is isomorphic to the monoid of all equivalence relations on $D$ equipped with the order “finer” and with the product:

$$x (\approx_a * \approx_b) y \iff \left( x \approx_a y, x \approx_b y \right) \quad \forall x, y \in D.$$ 

10.4 Multivalued ITs

Let $D = \text{Set}$, the category of sets, $TA$ is the set of all nonempty subsets of $A$ and $\gamma_{A,B}$ takes pair of sets $P, Q$ to their Cartesian product $P \times Q$, a subset of $A \times B$. This leads us to the category $\text{MVT}$ of multivalued ITs. Detailed study of this category may be found in [14]. Thus, the category $\text{MVT}$ consists of sets as objects and of multivalued maps (everywhere defined relations) as
morphisms (information transformers). Despite its simplicity, this class of ITs may be convenient when stochastic description of measurement error is inadequate.

So, a multivalued IT $a$ from $D$ to $R$

$$a: D \rightarrow R$$

is determined by a multivalued map, that is,

$$\forall x \in D \quad ax \subseteq R, \quad ax \neq \emptyset.$$

Define the composition and the product of multivalued ITs by the following expressions:

$$(b \circ a)(x) \overset{\text{def}}{=} \bigcup \{by \mid y \in ax\},$$

$$(a \ast b)(x) \overset{\text{def}}{=} ax \times bx.$$

The subcategory of deterministic ITs is actually the category of sets $\text{Set}$.

In addition to the trivial accuracy relation in the category of multivalued ITs one can put

$$a \triangleright b \overset{\text{def}}{\iff} \forall x \in D \ ax \subseteq bx.$$

These two accuracy relations lead to different informativeness relations [14], called (strong) informativeness $\succ$ and weak informativeness $\bowtie$.

For the both informativeness relations the classes of equivalent ITs with a fixed source $D$ can be described explicitly.

In the case of weak informativeness every class of equivalent ITs corresponds to a certain covering $P$ of the set $D$, such that if $P$ contains some set $B$ then it contains all its subsets:

$$\left( \exists B \in P \ (A \subseteq B) \right) \implies A \in P.$$

Moreover, a covering $P_1$ is more (weakly) informative than $P_2$ (namely, $P_1$ corresponds to a class of more (weakly) informative ITs than $P_2$) if $P_1$ is contained in $P_2$, that is,

$$P_1 \bowtie P_2 \overset{\text{def}}{\iff} P_1 \subseteq P_2.$$

In the case of (strong) informativeness every class of equivalent ITs corresponds to a covering $P$ of the set $D$, that satisfy the more complex condition:

$$\left( \left( \exists B \in P \ (A \subseteq B) \right) \& \left( \exists B \subseteq P \ A = \bigcup B \right) \right) \implies A \in P.$$
In this case

\[ P_1 \supseteq P_2 \iff \left( (\forall A \in P_1 \ \exists B \in P_2 \ A \subseteq B \right) \]

\& \left( (\forall B \in P_2 \ \exists A \subseteq P_1 \ B = \bigcup A) \right) \).

In the category of multivalued information transformers every IT is dominated (in the sense of the partial order \( \supset \)) by a deterministic IT. Thus, in the monotone decision-making problem one can search optimal decision strategies in the class of deterministic ones.

For every joint distribution in the category of multivalued ITs there exist conditional distributions [13]. Therefore, in decision problems with a prior information, the Bayesian approach can be effectively applied.

10.5 Categories of fuzzy information transformers

Here we define two categories of fuzzy information transformers \( \textbf{FMT} \) and \( \textbf{FPT} \) that correspond to different fuzzy theories [15] Let \( D = \text{Set}, T A \) is the set of all normalized fuzzy subsets of \( A \) and \( \gamma_{A,B} \) takes pair of fuzzy subsets \( P, Q \) to the fuzzy subset \( P \times Q \), \( (P \times Q)(x,y) = P(x) \otimes Q(y) \), where the operation \( \otimes \) may be defined in a variety of ways. The most common are the minimum (the category \( \textbf{FMT} \)) and product (the category \( \textbf{FPT} \)) operations [15].

Objects of these categories are arbitrary sets and morphisms are everywhere defined fuzzy maps, namely, maps that take an element to a normed fuzzy set (a fuzzy set \( A \) is normed if supremum of its membership function \( \mu_A \) is 1). Thus, an information transformer \( a: A \rightarrow B \) is defined by a membership function \( \mu_{ax}(y) \) which is interpreted as the grade of membership of an element \( y \in B \) to a fuzzy set \( ax \) for every element \( x \in A \).

The category \( \textbf{FMT} \). Suppose \( a: A \rightarrow B \) and \( b: B \rightarrow C \) are some fuzzy maps. We define their composition \( b \circ a \) as follows: for every element \( x \in A \) put

\[ \mu_{(b \circ a)x}(z) \stackrel{\text{def}}{=} \sup_{y \in B} \min \left( \mu_{ax}(y), \mu_{by}(z) \right) . \]

For a pairs of fuzzy information transformers \( a: D \rightarrow A \) and \( b: D \rightarrow B \) with the common source \( D \), we define their product as the IT that acts from \( D \) to the Cartesian product \( A \times B \), such that

\[ \mu_{(a \times b)x}(y, z) \stackrel{\text{def}}{=} \min \left( \mu_{ax}(y), \mu_{by}(z) \right) . \]
The category **FPT**. Define the *composition* and the *product* by the following expressions:

\[
\mu_{(b \circ a)x}(z) \overset{\text{def}}{=} \sup_{y \in \mathcal{B}} \left( \mu_{ax}(y) \cdot \mu_{by}(z) \right),
\]

\[
\mu_{(a \ast b)x}(y, z) \overset{\text{def}}{=} \mu_{ax}(y) \cdot \mu_{by}(z).
\]

In the both defined above categories of fuzzy information transformers the subcategory of *deterministic* ITs is (isomorphic to) the category of sets **Set**. Let \( g: \mathcal{A} \to \mathcal{B} \) be some map (morphism in **Set**). Define the corresponding fuzzy IT (namely, a fuzzy map, which is obviously, everywhere defined) \( \tilde{g}: \mathcal{A} \to \mathcal{B} \) in the following way:

\[
\mu_{\tilde{g}(x)}(y) \overset{\text{def}}{=} \delta_{g(x), y} = \begin{cases} 1, & \text{if } g(x) = y, \\ 0, & \text{if } g(x) \neq y. \end{cases}
\]

Concerning the choice of accuracy relation, note, that in these IT-categories, like in the category of multivalued ITs, apart from the trivial accuracy relation one can put for \( a, b: \mathcal{A} \to \mathcal{B} \)

\[
\forall x \in \mathcal{A} \forall y \in \mathcal{B} \quad \mu_{ax}(y) \leq \mu_{bx}(y).
\]

In each fuzzy IT-category these two choices lead to two different informativeness relations, namely the strong and the weak ones.

Like in the categories of linear and multivalued ITs discussed above, monotone decision-making problems admit restriction of the class of optimal decision strategies to deterministic ITs without loss of quality.

It was shown in [15] that for every joint distribution in the categories of fuzzy ITs there exist conditional distributions. It allows Bayesian approach and makes use of Bayesian principle in decision problems with a prior information for fuzzy ITs [15] (see also [16–18] where connections between fuzzy decision problems and the underlying fuzzy logic are studied).

In this section we introduced only several examples of IT-categories. Let us also remark that there is an extensive literature that studies a wide spectrum of categories which are close in their structure to IT-categories [35, 41–46].
