Abstract: Dilithium manganese oxide (LMO) thin film was newly fabricated as an active material on a fluorinated-tin-oxide pre-coated glass electrode by a wet process. A stable LMO precursor solution was developed through the reaction of lithium and manganese acetates with butylamine in ethanol. A spin-coated precursor film was heat-treated at 500 °C in air for 0.5 h. The X-ray diffraction pattern indicates that the resultant film consists of layer-structured LMO crystals. The X-ray photoelectron spectra of LMO thin film suggests that the ratio of Mn$^{3+}$/Mn$^{4+}$ is 1/4, and the chemical formula can be expressed as Li$_{2}$MnO$_{2.9}$. A device was assembled with O-deficient LMO and TiO$_{2}$ thin films as each active material, along with an electrolytic solution involving LiPF$_{6}$. The charging voltages (2.67 and 1.45 V) of this device were recorded by applying a constant current of 0.2 mA and using 1-sun irradiation without external power supply, respectively. The voltages delivered by this cobalt-free device were 0.63 and 0.13 V higher, respectively, than the corresponding device assembled with lithium cobalt oxide as a cathodic active material.

Keywords: Li$_{2}$MnO$_{3}$ thin film; photovoltaic device; lithium-ion battery; molecular precursor method

1. Introduction

Recently, we reported on the fabrication of a new photovoltaic lithium-ion battery (PV-LIB) with LiCoO$_{2}$ (LCO) and titania thin films for cathodic and anodic active materials, respectively. These materials were fabricated on a fluorinated-tin-oxide (FTO) pre-coated glass substrate using the molecular precursor method (MPM) [1]. The MPM is one of the wet chemical processes, which was developed in our group for fabricating thin films of various metals, metal oxides, and phosphate compounds [1–13]. This method has many advantages, such as excellent stability, homogeneity, miscibility, and compatibility.

An efficient lithium-ion battery (LIB) using LCO, which is widely used and also assembled in the previous PV-LIB, was first reported by Mizushima et al. in 1980 [14]. Various materials have been studied as an alternative for LCO because cobalt is a rare metal element. Kalyani et al. reported in 1999 that dilithium manganese (IV) oxide (Li$_{2}$MnO$_{3}$, LMO) is an electrochemically active material, and offered suggestions for the removal/insertion processes of lithium-ion [15]. This study and other studies have given increased attention to LMO, which has a layered crystal structure analogous to LCO, as one of the most promising candidates for the cathodic active material of LIB [15–20]. The LMO thin films have been fabricated using radiofrequency sputtering with post-annealing at 850 °C in air, and pulsed laser deposition with a substrate temperature higher than 650 °C during deposition [16–20].
In these physical vapor depositions, the vacuum system and associated maintenance require high costs [21]. There is currently no report, however, on LMO thin film fabrication using the low-cost wet-chemical process.

We report on the fabrication of LMO thin film on an FTO pre-coated glass substrate using a solution-based process, and the corresponding application to cobalt-free PV-LIB.

2. Materials and Methods

2.1. Materials

Lithium acetate, butylamine, 2-propanol, titania molecular precursor solution (Ti$^{4+} = 0.5$ mmol g$^{-1}$), and molecular sieves 4A were purchased from FUJIFILM Wako Pure Chemical Corporation, Osaka, Japan. Manganese (II) acetate was purchased from Alfa Aesar, Lancashire, United Kingdom. The LiPF$_6$ solution of 1 mol L$^{-1}$ in ethylene carbonate/dimethyl carbonate (1:1 by volume) was purchased from KISHIDA CHEMICAL Co. Ltd., Osaka, Japan. Ethanol was purchased from Ueno Corporation, Osaka, Japan, and was dried with molecular sieves 4A before use. Other materials were used without further purification. An FTO pre-coated soda-lime glass substrate was purchased from AGC Inc., Tokyo, Japan. The substrates with dimensions of 20 x 33 x 1.8 mm$^3$ were prepared and ultra-sonicated in 2-propanol for 0.5 h, and then dried in a drying oven at 70 °C before use.

2.2. Preparation of LMO Precursor Solution

The LMO precursor solution ($S_{\text{LMO}}$) was prepared by mixing 0.27 g (4.0 mmol) of lithium acetate, 0.35 g (2.0 mmol g) of manganese acetate, and 1.79 g (24.0 mmol) of butylamine in 10 g of ethanol with mechanical stirring at 25 °C for three h. The concentration of Li$^+$ and Mn$^{2+}$ ions was adjusted to 0.33 and 0.17 mmol g$^{-1}$, respectively.

2.3. Coating and Heat-treating Procedures

Before the coating process, FTO pre-coated glass substrates were partially covered with masking tape to limit the size of the coating area to 20' 20 mm$^2$. The precursor films of LMO and titania on the FTO pre-coated glass substrates were formed by spin-coating each 50 µL of $S_{\text{LMO}}$ and commercially available titania precursor solution at 25 °C. A two-step process (first step at 500 rpm for 5 s, and second step at 2000 rpm for 30 s) was used in the spin-coating method. The precursor films obtained by pre-heating in a drying oven at 70 °C for 10 min were heat-treated in the air at 500 °C for 0.5 h. The resultant thin films were denoted as $F_{\text{LMO}}$ and $F_{\text{Titania}}$, respectively. In order to determine the crystal structure of LMO, another thin film of three-layered $F'_{\text{LMO}}$ was also prepared using the same procedure from the spin-coated precursor film on $F_{\text{LMO}}$ using $S_{\text{LMO}}$ repeatedly.

2.4. Crystal Structure of Thin Films

The crystal structure of $F_{\text{LMO}}$, $F'_{\text{LMO}}$, and $F_{\text{Titania}}$ were determined using X-ray diffraction (XRD) with a SmartLab X-ray diffractometer (Rigaku Corporation, Tokyo, Japan). This diffractometer utilized a Cu-Kα radiation source at a power of 45 kV and 200 mA. Parallel beam optics at an incidence angle 0.3° was used in the 2θ range of 10–80°. The scanning step width was 0.05°, and the speed was 5° min$^{-1}$.

2.5. Surface Morphology and Thin Film Thickness

The surface morphology and cross-sectional images of $F_{\text{LMO}}$, $F'_{\text{LMO}}$, and $F_{\text{Titania}}$ were observed by a field-emission scanning electron microscopy (FE-SEM) using JSM-6701F (JEOL Ltd., Tokyo, Japan) at an accelerating voltage of 5 kV. The average grain size of each thin film was calculated from ten randomly selected and different grains. The film thickness was determined as the average height at ten different positions of each cross-sectional image.
2.6. Chemical Characterization of Thin Films

X-ray photoelectron spectroscopy (XPS) spectra of F\textsubscript{LMO} were measured by a JPS-9030 spectrometer (JEOL Ltd., Tokyo, Japan) using a non-monochromatic Al-K\textsubscript{α} X-ray radiation (1486.6 eV) and a step width of 0.1 eV. The F\textsubscript{LMO} was sputtered with Ar ions at an acceleration voltage of 300 V and a current density of 5.1 mA cm\textsuperscript{−2} for 60 s before XPS analysis. The binding energies of the XPS spectra data were corrected with reference to the C 1 s peak at 285.0 eV. After binding energy correction, the Shirley-type baseline and peak positions were calculated using Origin 2018 software (OriginLab Corporation, MA, USA).

The Li 1s/Mn 3p and Mn 3s peaks were deconvoluted by a nonlinear least-square method with the use of the Voigt function. The peak fitting converged when the difference of reduced chi-square ($\chi^2$), which is the $\chi^2$ value divided by the number of degrees of freedom, reached the tolerance value of $10^{-9}$. $\chi^2$ is represented by the following Equation (1), where $I_0$ is the observed spectral intensity and $I_C$ is the calculated value of the intensity obtained by the fitting:

$$\chi^2 = \sum (I_0 - I_C)^2$$

(1)

The Li/Mn ratio of F\textsubscript{LMO} was evaluated from the peak areas of Li 1s and Mn 2p\textsubscript{3/2} in the XPS spectra using relative sensitivity factors obtained from SpecSurf software (JEOL Ltd., Tokyo, Japan), and can be represented by the following Equation (2):

$$\frac{\text{peak area of Li 1s}}{\text{relative sensitivity factor of Li 1s for Al Kα : 0.2504}} \div \frac{\text{peak area of Mn 2p}_{3/2}}{\text{relative sensitivity factor of Mn 2p}_{3/2} \text{ for Al Kα : 36.1170}}$$

(2)

The average oxidation state (AOS) of Mn was obtained using the linear correlation between AOS of Mn and $\Delta E$, which can be expressed by the following Equation (3) [22], where $\Delta E$ represents the magnitude of the Mn 3s splitting. The value was calculated by the energy difference between the deconvoluted peaks assignable to Mn 3s level:

$$\text{AOS} = 8.956 - 1.126 \cdot \Delta E$$

(3)

2.7. Charge/discharge Cyclic Test on the Assembled Device

The electrodes F\textsubscript{LMO}, F\textsubscript{LMO}', and F\textsubscript{Titania} were assembled into a sealed sandwich-type device, with an electrolytic solution utilizing LiPF\textsubscript{6} (Scheme 1). Teflon sheets (Taisei Kagaku Co., Ltd., Tokyo, Japan) and double-coated adhesive polyester tapes (Nitto Denko Corporation, Osaka, Japan) were used as a spacer with a thickness of 200 $\mu$m between the electrodes.

The charge/discharge cyclic test of the device was performed in accordance with the previously reported procedures [1,12]. In the charge/discharge current-insertion mode of 30 cycles at 60 s intervals, a constant current of 0.2 mA was applied during charging and then self-discharged. The voltage change of the device was recorded by a DC voltage source/monitor 6241 A (ADC Co., Ltd., Saitama, Japan). In the light-irradiation mode, the repeated 1-sun irradiation using a Lax-Cute solar simulator (Asahi Spectra Co., Ltd., Tokyo, Japan) and self-discharge in dark conditions was performed 30 times at 60 s intervals. The voltage during the cyclic test by light-irradiation was measured by a digital multimeter VOAC7523H (IWATSU ELECTRIC Co., Ltd., Tokyo, Japan).
3. Results

3.1. XRD Patterns of FLMO, F'LMO, and FTitania

Figure 1a shows the XRD pattern of FLMO and F'LMO. Three peaks at 2θ = 18.8, 21.4, and 44.7° for both FLMO and F'LMO and three peaks at 2θ = 37.1, 59.1, and 65.4° for F'LMO are assignable to the (001), (110), (−132), (131), (132), and (060) crystal phases of layered rock-salt Li$_2$MnO$_3$ (ICDD card No. 01-084-1634), respectively. The additional twelve peaks at 2θ = 26.6, 34.0, 38.0, 39.1, 42.7, 51.8, 54.9, 61.9, 64.8, 66.0, 71.2, and 78.7°, which can be ascribed to SnO$_2$ phases (ICDD card No. 00-041-1445) in FTO, are observed. The XRD pattern of FTitania is also shown in Figure 1b. Five peaks at 2θ = 25.4, 48.1, 62.9, 70.2, and 75.1° are assignable to (101), (200), (204), (220), and (215) phases of anatase (ICDD card No. 00-064-0863), respectively. The additional nine peaks at 2θ = 34.0, 38.0, 51.8, 54.9, 61.9, 64.8, 66.0, 71.2, and 78.7°, which can be ascribed to SnO$_2$ in FTO, were also observed.

**Scheme 1.** The schematic illustration of a sealed sandwich-type device assembled by FLMO and FTitania with an electrolytic solution utilizing LiPF$_6$.

**Figure 1.** XRD patterns of (a) FLMO, F'LMO, and (b) FTitania on the fluorinated-tin-oxide (FTO) pre-coated glass substrate with thicknesses of 80, 190, and 150 nm, respectively. Relevant standard patterns are included for comparison along with XRD patterns of thin films. The peaks are denoted as follows: ▼ Dilithium manganese oxide (LMO), ▲ TiO$_2$, ○ FTO.
3.2. Surface Morphology and Film Thickness of FLMO, F’LMO, and FTitania

Figure 2 shows the surface and cross-sectional images of (a) FLMO, (b) F’LMO, and (c) FTitania, observed by FE-SEM. The surface morphologies of three thin films revealed that tiny grains with sizes of 17(2) nm are well connected with no apparent crack. The standard deviation here is indicated in parentheses. From the cross-sectional FE-SEM images, the thicknesses of FLMO, F’LMO, and FTitania could be determined as 80(20), 190(20), and 150(20) nm, respectively.

![Figure 2](image)

Figure 2. The surface and cross-sectional images, observed by field emission scanning electron microscopy (FE-SEM), of (a) FLMO, (b) F’LMO, and (c) FTitania on FTO pre-coated glass substrates.

3.3. X-ray Photoelectron Spectra and Average Oxidation State of Mn

Figure 3 shows the XPS spectra of FLMO. Three binding energy ranges corresponding to the Li 1s/Mn 3p, Mn 2p3/2, and Mn 3s orbitals are presented. The binding energy of 53.6 eV is assignable to Li 1s orbital electrons, which are bonded to Oxygen (Li–O) [23]. The four binding energies of 48.7, 84.5, 89.1, and 641.2 eV can be assigned to the Mn 3p [24], Mn 3s [22,25,26], and Mn 2p3/2 [27] orbital electrons, respectively, and these electrons are bonded to oxygen (Mn–O).

![Figure 3](image)

Figure 3. X-ray photoelectron spectroscopy (XPS) spectra of (a) Li 1s/Mn 3p, (b) Mn 3s, and (c) Mn 2p3/2 of surface of FLMO. The thick solid line indicates the original data of X-ray photoelectron spectroscopy (XPS). The thin solid line indicates the Shirley-type baseline. The dashed and dotted curves indicate theoretically fitted curves by assuming the Voigt distribution.
The calculated Li/Mn ratio of Li–O bond to Mn–O bond in F$_{LMO}$, to which binding energies of 53.6 and 641.2 eV were assigned, respectively, is 2.0. In addition, the estimated AOS value of manganese in F$_{LMO}$ was determined to be 3.8, according to Equation (3).

3.4. Charge/discharge Cyclic Test on the Assembled Device

Figure 4 shows the curves of the voltage change during the charge/discharge cyclic test on a sealed sandwich-type device using F$_{LMO}$. Table 1 shows the averaged charge/discharge voltages during current-insertion and light-irradiation to the device using the LMO with a thickness of 80 nm and the LCO with a thickness of 70 nm as the cathodic active materials. The test was performed under identical conditions to form a comparison to PV-LIB in the previous study using LCO [1]. In Figure 4, the dashed line represents the result of the charge/discharge current-insertion mode. The averaged charging voltage in the range from 4 to 30 cycles was 2.67 V while applying a constant current of 0.2 mA. The averaged value in the cycle range, 2.21 V, was detected during the self-discharge process. The voltage change using the 1-sun irradiation is shown in a solid line in Figure 4. The averaged voltages in the corresponding cycle-range were 1.45 V under 1-sun irradiation and 1.44 V in dark conditions. On the other hand, the device using the F’$_{LMO}$ was overcharged by applying a constant current of 0.2 mA, which might be due to its high resistance.

![Figure 4.](image)

**Figure 4.** The charge/discharge cyclic tests of the assembled device; voltage changes by applying a constant current of 0.2 mA (dashed line) and under 1-sun irradiation (solid line), respectively, at 60 s intervals.

| Cathodic Active Material | 0.2 mA Current-Insertion Mode | Light-Irradiation Mode |
|-------------------------|-------------------------------|-------------------------|
|                         | Charge (V) | Discharge (V) | Charge (V) | Discharge (V) |
| LMO                     | 2.67       | 2.21          | 1.45       | 1.44           |
| LCO [1]                 | 2.04       | 1.82          | 1.32       | 1.29           |

**Table 1.** The averaged charge/discharge voltages during current-insertion and light-irradiation to the device using the LMO of this study and the LiCoO$_2$ (LCO) of the previous study as the cathodic active materials.
4. Discussion

4.1. Preparation of LMO Precursor Solution

A precursor solution $S_{\text{LMO}}$, which was prepared by the reaction between lithium acetate, manganese acetate, and butylamine in dehydrated ethanol, can be stored as a clear solution for at least three months under usual storage conditions at 25 °C. Butylamine plays an important role to dissolve both acetates of Li$^{+}$ and Mn$^{2+}$ into ethanol, and the amount of butylamine was determined to assume the coordination number of 4 against both metallic ions. As a result, the obtained precursor solution has excellent stability and compatibility for the FTO pre-coated glass substrate using the spin-coating procedure. It is important to note that the stable precursor solution could be prepared in a simple one-pot process without using a multidentate ligand, which is usually employed in the conventional MPM.

4.2. Layered Rock-Salt Phase LMO and Anatase-Type Titania by a Chemical Process

The resultant LMO thin film crystallized in the layered rock-salt structure on the FTO pre-coated glass substrate (Figure 1a). Because the Li/Mn ratio for $F_{\text{LMO}}$ was found to be just 2.0 from the XPS analysis, the XPS result is in agreement with the above-mentioned XRD result. Furthermore, the thickness of $F_{\text{LMO}}$ (80 nm) is comparable to that of LCO on the FTO pre-coated glass substrate, which was used as the cathodic active material for PV-LIB (70 nm) in the previous study [1]. Thus, the thin film of the desired LMO was successfully obtained using a simple chemical process for the first time.

In this study, we fabricated titania thin film using a commercially available molecular precursor solution. As shown in Figure 1b, the crystal structure of $F_{\text{Titania}}$ obtained by heat-treating the spin-coated precursor film at 500 °C in the air is identical to that of our previous study [1], which confirms the reproducibility of titania thin film fabrication by the MPM. Our group recently reported that transparent anatase thin film could be used as the anodic active material of PV-LIB due to its properties as an $n$-type semiconductor, which can be excited by light irradiation.

4.3. Formation of Mixed-Valent Mn Ions and O-Deficient in Thin Film

The 3s core level of 3d transition metal ions is known to exhibit an exchange splitting [28]. Galakhov et al. reported that the magnitude of the Mn 3s splitting is promising for identifying the AOS of manganese [26]. The AOS of manganese was calculated by the energy difference between the two peaks ($\Delta E$) due to Mn 3s orbital, which was obtained from the deconvoluted peaks of the XPS spectrum (Figure 3b). This result clearly indicates the presence of Mn$^{3+}$ ion in $F_{\text{LMO}}$ at a Mn$^{3+}$/Mn$^{4+}$ ratio of 1/4. To maintain the electrical neutrality of LMO, the chemical formula can be expressed as Li$_2$MnO$_{2.9}$. These results suggest that the original Mn$^{2+}$ ion was oxidized into tri- and tetravalent states during heat-treatment in the air in the above-described ratio.

There was no report on the thin film fabrication of an O-deficient LMO, although the O-deficient powders could be formed by adding reductants such as NaBH$_4$, CaH$_2$, and LiH into Li$_2$MnO$_3$ powders [25,29]. In our previous study, the O-deficient anatase thin film was obtained by the MPM through post-annealing in the air of a precursor film including the Ti complex of ethylenediamine-N, N', N'-tetraacetic acid (EDTA) and heat-treating in Ar gas flow at 500 °C [3]. The elimination of H, C, and N atoms from the EDTA complex can thus lead to O-deficient anatase. In our study, an O-deficient LMO thin film was fabricated only by heat-treatment of the spin-coated precursor film in air, even though no EDTA complex was involved. It can be assumed that the formation of an O-deficient LMO occurred during the elimination of acetate and butylamine from the precursor film.

4.4. Delivered Voltages by the Assembled Device

Anatase is an attractive anodic material with the charge/discharge plateau voltages observed at 1.5–2.0 V vs. Li/Li$^+$, which is the corresponding potential of Li$^+$ insertion/extraction that anatase does
not suffer from lithium-plating [30,31]. A plateau region at 4.5–4.6 V vs. Li/Li$^+$ was observed in LMO during the initial charging [19,32]. Based on these plateau values, the potential difference between anatase and LMO can be theoretically estimated in the range of 2.5–3.1 V. Using the present device with LMO and anatase thin films, 2.67 V was recorded as the average charging potential by applying a constant current of 0.2 mA. This value agrees with the aforementioned theoretical value for a typical LIB using the corresponding active materials.

The present device that utilizes F$_1$LMO with a delivered potential of 2.67 V proves the ability of a LIB to deliver 0.63 V higher voltages than the alternate device that utilizes LCO thin film during charging operation at a constant current of 0.2 mA [1]. Furthermore, the voltage delivered under 1-sun irradiation is 0.13 V higher than the device that uses LCO thin film [1].

5. Conclusions

A novel precursor solution was prepared by mixing lithium acetate and manganese acetate under the presence of butylamine in ethanol. The solution can be developed on an FTO pre-coated glass substrate using the spin-coating method. Heat-treating of the formed precursor film at 500 $^\circ$C yielded LMO thin film in the desired layer structure. The chemical formula of the LMO thin film was estimated to be Li$_2$MnO$_{2.9}$ by XPS spectra, indicating the incorporation of Mn$^{3+}$ ion and O-deficiency in the structure. Thus, chemical fabrication of an O-deficient and layer-structured LMO thin film on an FTO pre-coated glass substrate was achieved for the first time. A device was successfully assembled with the LMO, titania, and electrolytic solution involving LiPF$_6$. The voltages (2.67 and 1.45 V) from the device were delivered by applying a constant current of 0.2 mA and 1-sun irradiation, respectively, with no external power supply in either case. Both voltages from this present device by applying a constant current and light irradiation were delivered 0.63 and 0.13 V higher, respectively, than the corresponding PV-LIB assembled with LCO thin film as a cathodic active material. A cobalt-free PV-LIB can be achieved by using the O-deficient LMO thin film, and this device delivers higher voltages both by current insertion and light irradiation than voltages from the previous PV-LIB using LCO.
