CASTELNUOVO THEORY AND THE GEOMETRIC SCHOTTKY PROBLEM

GIUSEPPE PARESCHI AND MIHNEA POPA

1. Introduction

The aim of this paper is to show that Castelnuovo theory in projective space (cf. [ACGH] Ch.III §2 and [GH] Ch.4 §3) has a precise analogue for abelian varieties. This can be quite surprisingly related in a concrete way to the geometric Schottky problem, namely the problem of identifying Jacobians among all principally polarized abelian varieties (ppav’s) via geometric conditions on the polarization. The main result is that a ppav satisfies a direct analogue of the Castelnuovo Lemma if and only if it is a Jacobian. We prove or conjecture other results which show an extremely close parallel between geometry in projective space and Schottky-type projective geometry on abelian varieties.

On a ppav $(A, \Theta)$ of dimension $g$ one can make sense of what it means for a finite set $\Gamma$ of at least $g+1$ distinct points to be in general position (we call this theta-general position, cf. §3): we simply require for any subset $Y \subset \Gamma$ of $g+1$ points to be theta-independent, i.e. for any $g$ points of $Y$ there is a translate of $\Theta$ containing them and avoiding the remaining point. It turns out that general points on any non-degenerate curve are in theta-general position. On a Jacobian $J(C)$, points on an Abel-Jacobi curve impose the minimal number of conditions, namely $g+1$, on the linear series $|O_A(2\Theta)|$ for $\alpha \in J(C)$ general (Proposition 3.6 and Example 3.7). The main result we prove is the following theorem – we refer to §2 for a detailed description of the context in which it should be integrated.

**Theorem A** (“Castelnuovo-Schottky Lemma”). Let $(A, \Theta)$ be an irreducible principally polarized abelian variety of dimension $g$, and let $\Gamma$ be a set of $n \geq g+2$ points on $A$ in theta general position, imposing only $g+1$ conditions on the linear series $|O_A(2\Theta)\otimes \alpha|$ for $\alpha$ general in $\tilde{A}$. Then $(A, \Theta)$ is the canonically polarized Jacobian of a curve $C$ and $\Gamma \subset C$ for a unique Abel-Jacobi embedding $C \subset J(C)$.

Roughly speaking, the key points in the proof of the Theorem are the following. Given a set of points $\Gamma$ in theta-general position and imposing generically only $g+1$ conditions on $|O_A(2\Theta)\otimes \alpha|$, and given a subset $Z \subset \Gamma$ with $|Z| = g+1$, we consider the locus $V(Z)$ of $\alpha \in \tilde{A}$ such that $Z$ fails to impose independent conditions on $|O_A(2\Theta)\otimes \alpha|$. It turns out that $V(Z)$ is a theta-translate, precisely described in function of $Z$ (cf. Proposition 5.1). We prove a formula for the intersection of theta-translates of type $V(Z)$ (cf. Proposition 5.11). The intersection formula yields the existence of a certain positive-dimensional family of trisecants to the Kummer variety (cf. Theorem 5.2), at which stage the Gunning-Welters criterion [We1] implies that $(A, \Theta)$ is a Jacobian. This approach also carries a natural way to recover the curve. In fact, in analogy with the classical Castelnuovo setting, the curve $C$ is recovered as the base locus of a continuous
system of divisors algebraically equivalent to $2\Theta$, containing $\Gamma$ (cf. Corollary [L3]). In particular this provides another proof of Torelli. An important ingredient is a previous result on the regularity of an Abel-Jacobi curve (cf. [PP1], §4).

In keeping with the picture suggested by Castelnuovo theory, we also establish a genus bound for non-degenerate curves in ppav’s.

**Theorem B.** Let $(A, \Theta)$ be a $g$-dimensional irreducible ppav. Let $C'$ be a smooth curve of genus $\gamma$, admitting a birational map onto a non-degenerate curve $C$ of degree $d := C \cdot \Theta$ in $A$. Let $m = \lfloor \frac{d - 1}{g} \rfloor$, so that $d - 1 = mg + \epsilon$, with $0 \leq \epsilon < g$. Then

$$\gamma \leq \left(\frac{m + 1}{2}\right)g + (m + 1)\epsilon + 1.$$ 

Moreover, the inequality is strict for $g \geq 3$ and $d \geq g + 2$.

The bound is quadratic in the degree, of leading term $\frac{d^2}{2g}$, so of the order suggested by curves in projective space. It is optimal for abelian surfaces, but the Castelnuovo-Schottky Lemma implies that in higher dimensions – unlike in the case of projective space – there is room for improvement (cf. §6).

We defer for the next section a detailed discussion of the context described in this Introduction, as well as of conjectural developments and connections with our previous work concerning regularity. Let us mention here that, as a consequence of criteria involving $M$-regularity, in §7 we show how to attach a canonical divisor class to a uniform collection of points $\Gamma$ failing to impose independent conditions on 2-theta functions generically. This concept seems to hold the key for future developments.

Finally, we mention that the analogue of Theorem A in the case of finite schemes, in the spirit of the Eisenbud-Harris generalization of the Castelnuovo Lemma ([EH2], [EH3]), will appear in work of M. Lahoz [L].

**Acknowledgements.** We would like to thank Ciro Ciliberto, Olivier Debarre, Lawrence Ein, Joe Harris and Elham Izadi, for their interest, suggestions and answers to numerous questions. We are grateful to Martí Lahoz and Juan Carlos Naranjo for pointing out an error in a previous version of the paper. Special thanks are due to Sam Grushevsky for correspondence and for communicating to us his work [Gr1], which contains a statement close to our first theorem (cf. §5.2 below for the precise statement and comparison). We would also like to emphasize that we realized our main theorem might also work for $g + 2$ points, as opposed to $g + 3$ or more, only after seeing his paper.

2. A PARALLEL BETWEEN PROJECTIVE SPACES AND PRINCIPALLY POLARIZED ABELIAN VARIETIES

The starting point of our work is the observation that on ppav’s there is an extensive similarity between basic facts related to the geometry of points in general linear position and of rational normal curves in projective space on one hand, and the geometry of points in theta-general position and of Abel-Jacobi embedded curves in Jacobians, on the other hand. This begins with a *point-theta divisor correspondence*, similar to the point-hyperplane correspondence between a projective space and its dual, and continues as described shortly. Ideally one then hopes that on ppav’s there are analogues of those aspects of projective geometry which are consequences of the “geometry of hyperplanes”. Among these aspects there is Castelnuovo
It becomes natural to expect an analogue of Castelnuovo theory for ppav’s, at least in its basic aspects. What is perhaps more surprising is that this turns out to lead to a geometric characterization of Jacobians (Theorem A in the Introduction) among all ppav’s.

Another – this time homological – fact pointing towards such a parallel stems from previous work in which we have explored an abelian varieties analogue of Castelnuovo-Mumford regularity (cf. [PP3] for an overview of this circle of ideas). This yields results on the geometry of abelian varieties and their subvarieties which parallel classical facts of projective geometry ([PP1],[PP2],[PP3],[De3]). Although in this paper we will mainly use elementary geometric methods and Jacobian criteria based on the existence of trisecants to the Kummer, it is our hope that they will eventually naturally combine with homological methods. A first step in this direction is made in §8.

We list below a few entries in this analogy, taking also the opportunity to introduce some notation. We recall that a ppav \((A,\Theta)\) is said to be irreducible if the theta-divisor \(\Theta\) is irreducible (as it is well known, this means that \((A,\Theta)\) is not isomorphic, as polarized variety, to the product of lower dimensional ppav’s). Let \((A,\Theta)\) be an irreducible ppav of dimension \(g\), and, without loss of generality, let us assume that \(\Theta\) is symmetric. For a smooth projective curve \(C\) of genus \(g\), let \((J(C),\Theta)\) be its Jacobian with the canonical principal polarization.

(1).[Point-divisor correspondence] (a) On \(\mathbb{P}^g\): the family of hyperplanes is parametrized by another projective space of the same dimension, the dual projective space \(\mathbb{P}^g\). Points of \(\mathbb{P}^g\) correspond to hyperplanes of \(\mathbb{P}^{g*}\), via \(p \mapsto D(p) = \{[H] \in \mathbb{P}^{g*} \mid p \in H\}\) and \(D \mapsto p(D) = \bigcap_{[H] \in D} H\).
(b) On \(A\): the family of divisors algebraically equivalent to \(\Theta\) is parametrized by the dual variety \(\hat{A}\): \(\{\Theta_\alpha\}_{\alpha \in \hat{A}}\), where \(\Theta_\alpha\) denotes the unique effective divisor in \(|\mathcal{O}_A(\Theta) \otimes \alpha|\). \(\hat{A}\) is principally polarized and there is a correspondence between points of \(A\) and theta-divisors in \(\hat{A}\) given by \(p \mapsto W(p) = \{\alpha \in \hat{A} \mid p \in \Theta_\alpha\}\) and \(W \mapsto p(W) = \bigcap_{\alpha \in W} \Theta_\alpha\). The divisor \(\hat{\Theta} := W(0)\) is symmetric.

Notation 2.1. (i) The polarization \(p \mapsto \mathcal{O}_A(\Theta_p - \Theta)\) provides the identification \(\Psi : (A,\Theta) \to (\hat{A},\hat{\Theta})\) so the \(\Theta_\alpha\)’s are translates of \(\Theta\). The translate \(\Theta_p\) (on \(A\)) is identified to the divisor \(\hat{\Theta}_p\) (on \(\hat{A}\)), where \(p\) is identified to a line bundle on \(\hat{A}\). We will denote both the above divisors \(\Theta_\alpha\) and we will refer to them as \(\text{theta-translates}\). With such identification, given \(p \in A\) and \(\alpha \in \hat{A}\), we have that \(\alpha \in \Theta_p\) if and only if \(p \in \Theta_\alpha\).
(ii) Given a subscheme \(Y \subset A\), we denote more generally
\[
W(Y) := \{\alpha \in \hat{A} \mid h^0(A, \mathcal{L}_Y(\Theta) \otimes \alpha) > 0\}.
\]
This locus parametrizes the theta-translates containing \(Y\). As \(\Theta\) is assumed to be symmetric, if \(Y = \{p\}\) then \(W(p)\) is identified to the theta-translate \(\Theta_p\) (cf. (i)).
(iii) Moreover we will denote \(\mathcal{O}((k\Theta)_\alpha) := \mathcal{O}(k\Theta) \otimes \alpha\).

(2).[General position and bound on the number of linear conditions] (a) On \(\mathbb{P}^g\): by Castelnuovo’s basic remark, based on reduction to the variety of \(k\)-forms which are product of linear ones, any linearly general subset \(\Gamma\) of \(\mathbb{P}^g\) imposes at least \(\min\{|\Gamma|, kg + 1\}\) independent

\footnote{Castelnuovo theory initiated with Castelnuovo’s work [Ca] around 1890. Modern accounts, as well as new results and research directions, have been given, among others, in [CI], [CIH], [ACGHI], [C], [R], [EGH]. The current perspective on the subject is mostly due to J. Harris.}

\footnote{It can be shown that \(W(Y)\) is equipped with a natural scheme structure.}
conditions on forms of degree \( k \) (cf. e.g. [GH] p.252).

(b) On \( A \): one can make sense of the notion of linear generality (\( \theta \)-generality, Definition 3.2 below). From an argument close to Castelnuovo’s it follows that any \( \theta \)-general subset \( \Gamma \) imposes at least \( \min\{\vert \Gamma \vert, (k - 1)g + 1\} \) conditions on \( H^0(O_A((k\Theta)_{\alpha})) \) for \( \alpha \) general in \( \hat{A} \) (cf. Proposition 3.6).

(3). [Effectivity of the bound and curves of minimal degree] (a) On \( P^g \): divisors of rational normal curves \( C \subset P^g \) show that the bound in the previous point is sharp. Rational normal curves are the curves of minimal degree in \( P^g \): a non-degenerate (i.e. not contained in a hyperplane) curve in \( P^g \) has degree \( C \cdot H \geq g \) and equality holds if and only if \( C \) is a rational normal curve.

(b) On \( A \): divisors of Abel-Jacobi curves show that the bound of the previous point is sharp (Example 3.7). Abel-Jacobi curves are the curves of minimal degree on \( A \): a curve \( C \) on \( A \) which is non-degenerate (in the sense of groups, i.e. no translate of \( C \) is contained in an abelian subvariety of \( A \)) has degree \( C \cdot \Theta \geq g \) and equality holds if and only if \( C \) is an Abel-Jacobi curve. This is (a particular case of) the Matsusaka-Ran criterion ([Ma], [Ra1], see also [BiL] 11.8.1). At least partially, it can be derived from the bound at the previous point (cf. Remark 3.8).

(4). [Castelnuovo’s Lemma] (a) On \( P^g \): Castelnuovo’s Lemma says that the example in (3a) is in fact the only one achieving equality: any set \( \Gamma \) of at least \( 2g + 3 \) points in \( P^g \) in linear general position, imposing only \( 2g + 1 \) conditions on quadrics, lies on a unique rational normal curve. The rational normal curve can be recovered as the base locus of the system of quadrics through \( \Gamma \) (cf. [GH], p.531).

(b) Under the hypothesis that \( \Theta \) is irreducible, the “Castelnuovo-Schottky Lemma” (Theorem A) says that the example in (3b) is the only one, providing a characterization of Jacobians. The analogue of the last part of (a) supplies a Torelli-type statement: the Abel-Jacobi curve can be recovered as the base locus of a certain system of divisors algebraically equivalent to \( 2 \Theta \) passing through \( \Gamma \) (cf. Corollary 4.3).

(5). [Castelnuovo’s bound] (a) On \( P^g \): Castelnuovo used the bound in (2a) to deduce his celebrated genus bound. It turns out that the genus of curves in \( P^g \) is bounded by a quadratic polynomial in the degree, whose leading term is \( \frac{d^2}{2(g - 1)} \) ([GH], p.251–252). The argument involves the number of conditions imposed by the general hyperplane section of a curve – which is proved to be in linear general position in \( P^{g-1} \) – to \( k \)-forms on \( P^{g-1} \).

(b) On \( A \): here some differences arise and the results so far are not optimal. On one hand, by Proposition 6.6 below, if the degree \( d = C \cdot \Theta > g \), then a general theta-section is already \( \theta \)-general. An argument similar to Castelnuovo’s then shows that the genus of a curve is bounded by a quadratic polynomial in \( d \) whose leading term is \( \frac{d^2}{2g} \) (Theorem B). On the other hand, unlike in the case of projective space, the same argument together with the Castelnuovo-Schottky Lemma also shows that this bound can be improved as soon as \( g \geq 3 \).

Conjectural extensions. So far for the results of this paper, which will be addressed starting with §3. An intriguing development would be to extend the parallel to all varieties of minimal degree.

(6). [Varieties of minimal degree versus varieties representing the minimal class] (a) On \( P^g \): the minimal degree of a non-degenerate subvariety of codimension \( c \geq 2 \) is \( c + 1 \). Varieties of minimal degree are (a cone over) one of the following: (1) a rational normal scroll; (2) a Veronese surface in \( P^5 \).

(b) It is conjectured in [De2] (together with some amount of evidence, including a proof on Jacobians) that on irreducible ppav’s the only subvarieties representing the minimal class, i.e.
of codimension \( d \) and of class \( [\Theta]^{d/d!} \), are: (1) the special varieties \( W_d \) in Jacobians; (2) the Fano surface of lines in the intermediate Jacobian of a cubic threefold.

There is a striking similarity between the two pictures (even the exceptions happen to both be surfaces in a five-fold!) and ideally there should be a geometric correspondence relating rational normal scrolls and the Veronese surface on one hand, and \( W_d \)’s and the Fano surface on the other hand. Finding similar properties shared by the two sets of varieties should already be important. In the next item we propose a step in this direction.

(7). [Cohomological regularity of the ideal sheaf] (a) On \( \mathbb{P}^9 \): a characterization of subvarieties of minimal degree is that they are the only 2-regular ones. This means that the twisted ideal sheaf \( I_{Y}(2) \) is 0-regular, in the sense of Castelnuovo-Mumford.
(b) On \( A \): in \cite{PP1} Theorem 4.1 (see also \cite{PP3} Theorem 4.3) we proved that the special subvarieties \( W_d \) in Jacobians are strongly 3-Theta-regular. This means that the twisted ideal sheaf \( I_{W_d}(2\Theta) \) satisfies the Index Theorem with index 0, i.e.

\[
H^i(I_{Y}(2\Theta)_\alpha)) = 0, \quad \forall i > 0, \quad \forall \alpha \in \text{Pic}^0(A).
\]

The same thing was recently checked by Höring \cite{Ho} for the Fano surface of lines, at least for a general cubic threefold. Therefore we are lead to the following:

**Conjecture 2.2.** A non-degenerate subvariety \( Y \) of an irreducible ppav \( (A, \Theta) \) represents a minimal class if and only if its ideal sheaf is strongly 3-Theta-regular.

Possible extensions of the Castelnuovo-Schottky Lemma. It is tempting to ask whether there is an interesting stratification of the moduli space of ppav’s via Castelnuovo-type conditions, namely the existence of collections of theta-general points, generically imposing few conditions on \( 2\Theta \)-linear series or, more generally, on theta-linear series of higher order. As in higher Castelnuovo theory for projective spaces \( [Fa, IH, EGH, Ci, Re] \) such conditions are related, at least conjecturally, to curves of low degree. On the other hand, there are exceptional abelian varieties containing non-degenerate curves of very low degree (say between \( g \) and \( 2g \)) and their geometry is quite delicate (we refer to \cite{De1} for interesting results and conjectures). This suggests that for ppav’s a more careful approach is necessary, most likely based on the existence of curves of maximal genus among those representing a given multiple of the minimal class. Note that such perspective is naturally related with Prym-Tyurin theory. To this end, we introduce in \$8\$ the concept of a divisor class attached to a uniform collection of points.

To be specific, the first natural higher Castelnuovo-Schottky problem arising is to characterize Prym varieties via a Castelnuovo-type condition. Here the idea is suggested by a beautiful result of Welters, essentially characterizing Prym varieties via the existence of a curve (the Abel-Prym curve) of maximal genus among those representing twice the minimal curve class (cf. \cite{We2}). Let \( \tilde{C} \) be an Abel-Prym curve in a Prym variety \( (P, \Xi) \). It turns out that a general divisor \( \Gamma \) of degree \( \geq 2g + 1 \) on \( \tilde{C} \) is theta-general and imposes generically \( n(\Gamma) = 2g \) conditions on \( H^0(O_P((2\Xi)_\alpha)) \). Moreover the divisor class of \( \Gamma \) is \( 2|\Xi| \) (see Example 7.2).

**Conjecture 2.3.** Let \( \Gamma \) be a theta-general, uniform collection of points on a ppav \( (A, \Theta) \), imposing generically \( n < |\Gamma| \) conditions on \( 2\Theta \)-linear series, and assume that the divisor class associated to \( \Gamma \) is \( [2\Theta] \). Then \( n \geq 2g \) and equality characterizes Prym varieties.

\(^3\)We have emphasized in \cite{PP1} that 3-Theta-regularity is the precise analogue of Castelnuovo-Mumford 2-regularity in projective space.
3. Theta general position and linear conditions on theta linear series of higher order

3.1. Theta general position. In this subsection we consider natural analogues on ppa\v{s} of basic notions of linear algebra, such as linear independence and linear general position. The main point is that, as on ppa\v{s} there is no direct analogue of linear subspaces of codimension higher than one, one is forced to define such notions using codimension-one objects only. Let \((A, \Theta)\) be a ppa\v{v} of dimension \(g\).

Definition/Notation 3.1. A collection \(Z\) of \(n \leq g + 1\) distinct points on \(A\) is theta-independent if, for any decomposition of \(Z\) as \(Z = Y \cup \{p\}\), there is a theta-translate \(\Theta_\gamma\) such that \(Y \subseteq \Theta_\gamma\) and \(p \notin \Theta_\gamma\). The subset of \(A\) parametrizing the family of such theta-translates is denoted \(\mathcal{H}^{Y,p}\). The closure of \(\mathcal{H}^{Y,p}\) is the union of some components of \(\bigcap_{q \in Y} \Theta_q\). Therefore \(\dim \mathcal{H}^{Y,p} \geq g - n + 1\) (the expected dimension).

Definition 3.2. A collection \(\Gamma\) of \(n \geq g + 1\) distinct points on \(A\) is theta-general if any \(Z \subseteq \Gamma\), with \(|Z| = g + 1\), is theta-independent. In other words: for any \(Y \subseteq \Gamma\) with \(|Y| = g\) and any \(p \in \Gamma - Y\) there exists at least one theta-translate \(\Theta_\gamma\) such that \(Y \subseteq \Theta_\gamma\) and \(p \notin \Theta_\gamma\).

Remark 3.3. All subsets of a theta-independent set are theta-independent. Indeed, let \(Z\) be theta-independent, and let \(T \subset Z\). Then, for any \(q \in T\), \(\mathcal{H}^{T,q}\) is non-empty, since obviously \(\mathcal{H}^{Z-(\{q\}),q} \subset \mathcal{H}^{T-(\{q\}),q}\).

Example 3.4. (a) It is easily seen that a general collection of \(n \geq g + 1\) points on any ppa\v{v} \((A, \Theta)\) is theta-general. More precisely, a general collection of \(n \geq g + 1\) points on any non-degenerate curve \(C\) in \(A\) is theta-general (see Proposition 6.6 for a stronger statement). On the other hand, on a curve \(C\) of degree \(d = C \cdot \Theta < g\) no collection of points on \(C\) is theta-general: a theta-translate meeting \(C\) in \(g\) points must contain \(C\).

(b) (Abel-Jacobi curves). Let \(C\) be a curve of genus \(g\) and let \(A = J(C)\). A general collection \(\Gamma\) of \(n \geq g + 1\) points on an Abel-Jacobi image of \(C\) is theta-general. It is interesting to see precisely how this happens. Let \(Y \subseteq C\) be a collection with \(|Y| = g\), general in the sense that \(h^0(\mathcal{O}_C(Y)) = 1\). Although \(\Theta^g = g!\), there is a unique theta-translate \(\Theta_{\gamma Y}\) such that \(\Theta_{\gamma Y} \cap C = Y\). This is an immediate consequence of the Jacobi inversion theorem. Hence for any other point \(p \in C\), \(\Theta_{\gamma Y}\) is the unique theta-translate containing \(Y\) and avoiding \(p\). This is formalized in the fact that – denoting \(W(Y)\) the locus of theta-translates containing \(Y\) (see Notation 2.1) – \(W(Y)\) has two irreducible components, one of which of unexpectedly big dimension. The first component is \(W(C)\), the locus of all the theta-translates containing the entire curve \(C\) (a \((g - 2)\)-dimensional variety isomorphic to \(W_{g-2}\)). The second one is an isolated point, corresponding to \(\Theta_{\gamma Y}\). This phenomenon actually characterizes Abel-Jacobi curves (see Remark 6.5 below)!

Remark 3.5. The notions of theta-independence and theta-generality are considerably weaker than the corresponding notions in projective space, essentially due to the large self-intersection of \(\Theta\). For example, note that three distinct points on \(A\) are always theta-independent. Moreover, the example above shows that there are theta-general sets contained in a large family of theta-translates.

3.2. Bound on the number of conditions. The natural analogue of Castelnuovo’s basic remark, on the number of conditions imposed on homogeneous forms of given degree, is given below. Note that for ppa\v{s} it is necessary to replace the linear system of hypersurfaces of degree \(k\) with the continuous system formed by all linear systems \(|(k\Theta)_\alpha|\), with \(\alpha \in \tilde{A}\).

Proposition 3.6. Let \(\Gamma \subset A\) be a theta-general set of points and let \(k \geq 2\). Then \(\Gamma\) imposes at least \(\min\{\text{length}(\Gamma) - k + 1, (k - 1)g + 1\}\) conditions on \(H^0(\mathcal{O}_A((k\Theta)_\alpha))\) for \(\alpha\) general in \(\tilde{A}\).
Proof. If \(|\Gamma| \geq (k-1)g + 1\), the statement means that there \(\Gamma\) contains a subset of \((k-1)g + 1\) points imposing independent conditions on \(H^0(O_A((k\Theta)_{\alpha}))\) for \(\alpha\) general in \(\hat{A}\). On the other hand, if \(|\Gamma| < (k-1)g + 1\), \(\Gamma\) can be completed to a theta-general subset of \((k-1)g + 1\) points. Therefore, it is enough to assume that \(|\Gamma| = (k-1)g + 1\), and prove that \(\Gamma\) imposes independent conditions on \(H^0(O_A((k\Theta)_{\alpha}))\) for \(\alpha\) general in \(\hat{A}\). Let’s write
\[
\Gamma = Y_1 \cup \ldots \cup Y_{k-1} \cup \{p\},
\]
with \(|Y_i| = g\) for any \(i\). For any \(i\), let \(\gamma_{Y_i, p}\) be a theta-translate containing \(Y_i\) and avoiding \(p\). We have that \(\Theta_{\gamma_{Y_1, p}} + \ldots + \Theta_{\gamma_{Y_{k-1}, p}} + \Theta_\beta\) contains \(\Gamma - \{p\}\) and avoids \(p\), unless \(\beta \in \Theta_p\). Therefore, for any \(\alpha \notin \Theta_{\gamma_{Y_1, p} + \ldots + \gamma_{Y_{k-1}, p} + p}\), there is a divisor in \(|(k\Theta)_{\alpha}|\) containing \(\Gamma - \{p\}\) and avoiding \(p\). As this can be done for any \(p\), we have that if \(\alpha \notin \cup_{p \in \Gamma} \Theta_{\gamma_{Y_1, p} + \ldots + \gamma_{Y_{k-1}, p} + p}\), then \(\Gamma\) imposes independent conditions on \(H^0(O_A((k\Theta)_{\alpha}))\).

Example 3.7 (Abel-Jacobi curves). The bound in the previous Proposition is sharp, as seen by looking at Abel-Jacobi curves. Let \(C \subset J(C)\) be one such. Then, for \(k \geq 2\) and for any \(\alpha \in \hat{A}\), \(h^0(O_C((k\Theta)_{\alpha})) = (k-1)g + 1\). Therefore a general collection of at least \((k-1)g + 1\) points on \(C\) imposes generically the minimal number of conditions – namely \((k-1)g + 1 – \text{on } H^0(O_A((k\Theta)_{\alpha}))\). In fact we can be precise: we have the exact sequence
\[
0 \rightarrow H^0(I_C(k\Theta_{\alpha})) \rightarrow H^0(I_{\Gamma}(k\Theta_{\alpha})) \rightarrow H^0(O_C(k\Theta_{\alpha} - \Gamma)) \rightarrow 0,
\]
where the last zero follows from the 3-Theta-regularity of \(C\) (cf. \(\S 2(7)\)). On the other hand, \(H^0(O_C(k\Theta_{\alpha} - \Gamma)) = 0\) for \(\alpha\) outside a proper closed subset isomorphic to \(W_d\), with \(d = kg - |\Gamma|\).

Example 3.8. To illustrate our point of view, let us show how the elementary Proposition 3.6 has as an immediate consequence the following easy but important step in the proof of the Matsusaka-Ran criterion: \textit{Let } \(C\) \textit{be a non-degenerate irreducible curve of degree } \(g\) \textit{in } \(A\). \textit{Then } \(p_a(C) \leq g\). \textit{(It follows that } \(C\) \textit{is smooth, irreducible, of genus } \(g\).)

Indeed, let \(k\) such that \(h^1(O_C((k\Theta)_{\alpha}))\) is generically zero. Let \(\Gamma\) be a general collection of distinct points on \(C\), with \(|\Gamma|\) big enough so that \(h^0(O_C((k\Theta)_{\alpha} - \Gamma)) = 0\) (e.g. \(|\Gamma| > kg\)). Therefore \(h^0(I_C((k\Theta)_{\alpha})) = h^0(I_{\Gamma}((k\Theta)_{\alpha}))\). By Example 3.1(a) \(\Gamma\) is theta-general, hence by Proposition 3.6 it imposes \(\geq (k-1)g + 1\) conditions on \(H^0(O_A((k\Theta)_{\alpha}))\) for \(\alpha\) general in \(\hat{A}\). This implies \(h^0(I_C((k\Theta)_{\alpha})) \leq h^0(O_A((k\Theta)_{\alpha}) - (k-1)g - 1\), and therefore \(h^0(O_C((k\Theta)_{\alpha})) \geq (k-1)g + 1\). Since \(h^1(O_C((k\Theta)_{\alpha})) = 0\), by Riemann-Roch we get \(h^0(O_C((k\Theta)_{\alpha})) = kg - p_a(C) + 1\). Hence \(p_a(C) \leq g\).

3.3. Loci of linear dependence. In this subsection we study the loci of \(\alpha \in \hat{A}\) such that a given finite set \(\Gamma\) fails to impose independent conditions on \(H^0(O_A((k\Theta)_{\alpha}))\).

Definition/Notation 3.9. Let \(\Gamma\) be a finite set (or scheme) on \(A\). We will consider the cohomological support loci
\[
V_r(I_{\Gamma}(k\Theta)) := \{\alpha \in \hat{A} \mid h^1(I_{\Gamma}((k\Theta)_{\alpha})) \geq r\}.
\]
For \(r = 1\), we will simply denote
\[
V(I_{\Gamma}(k\Theta)) := V_1(I_{\Gamma}(k\Theta)).
\]
Since \(h^i(O_A((k\Theta)_{\alpha})) = 0\) for any \(i > 0\) and \(\alpha \in \hat{A}\), \(V(I_{\Gamma}(k\Theta))\) is the locus of \(\alpha\)’s such that \(\Gamma\) fails to impose independent conditions on \(|(k\Theta)_{\alpha}|\). For example, by Proposition 3.6 for a theta-general collection \(\Gamma\) of at most \((k-1)g + 1\) points, \(V(I_{\Gamma}(k\Theta))\) is always a proper subvariety.
Definition/Notation 3.10. Let $\Gamma$ be a collection of points in $A$ and let $p \in \Gamma$. We denote

$$B(\mathcal{I}_{\Gamma \setminus \{p\}}(k\Theta), p) := \{ \alpha \in \hat{A} \mid p \text{ is in the base locus of } |\mathcal{I}_{\Gamma \setminus \{p\}}((k\Theta)_\alpha)| \}.$$  

We have the basic relation

$$V(\mathcal{I}_\Gamma(k\Theta)) = B(\mathcal{I}_{\Gamma \setminus \{p\}}(k\Theta), p) \cup V(\mathcal{I}_{\Gamma \setminus \{p\}}(k\Theta))$$

which simply means that if $\Gamma$ fails to impose independent conditions on $|(k\Theta)_\alpha|$, then either $p$ is in the base locus of $|\mathcal{I}_{\Gamma \setminus \{p\}}((k\Theta)_\alpha)|$ or $\Gamma \setminus \{p\}$ itself fails to impose independent conditions. Note also that, while $V(\mathcal{I}_\Gamma(k\Theta))$ and $V(\mathcal{I}_{\Gamma \setminus \{p\}}(k\Theta))$ are closed, $B(\mathcal{I}_{\Gamma \setminus \{p\}}(k\Theta), p)$ is only locally closed. We have also a second basic relation

$$V(\mathcal{I}_\Gamma(k\Theta)) = \bigcup_{p \in \Gamma} B(\mathcal{I}_{\Gamma \setminus \{p\}}(k\Theta), p).$$

The next Lemma describes the intersection of the linear dependence loci of two “close” collections.

Lemma 3.11. Let $Z, T$ be finite collections of distinct points of the same cardinality, having all points but one in common (in other words $|Z| = |T| = n$ and $|Z \cap T| = n - 1$). Then

$$V(\mathcal{I}_Z(k\Theta)) \cap V(\mathcal{I}_T(k\Theta)) = V_2(\mathcal{I}_{Z \cup T}(k\Theta)) \cup V(\mathcal{I}_{Z \cap T}(k\Theta)).$$

Proof. We prove that the left-hand side in contained in the right-hand side. Denote $p$ (resp. $q$) the only point of $Z$ (resp. of $T$) which does not belong to $Z \cap T$. Assume that both $Z$ and $T$ fail to impose independent conditions on $H^0(\mathcal{O}_A((k\Theta)_\alpha))$. If $\alpha \not\in V(\mathcal{I}_{Z \cap T})$ – i.e. if the $(n - 1)$ points of $Z \cap T$ impose independent conditions on $H^0(\mathcal{O}_A((k\Theta)_\alpha))$ – then $p$ is in the base locus of $|\mathcal{I}_{Z \cap T}((k\Theta)_\alpha)|$. Similarly $q$ is in the base locus of $|\mathcal{I}_{Z \cap T}((k\Theta)_\alpha)| = |\mathcal{I}_Z((k\Theta)_\alpha)|$. This means that $\alpha \in V_2(\mathcal{I}_{Z \cup T}(k\Theta))$. The reverse inclusion is obvious. 

We conclude with a rough estimate for the dimension of loci of linear dependence of theta-independent collections.

Lemma 3.12. Let $Y$ be a theta-independent collection of $n \leq g$ points on $A$. Then

$$\dim V(\mathcal{I}_Y(2\Theta)) \leq g - 2.$$  

Proof. Fix $p \in Y$ and decompose $Y$ as $Y = T \cup \{p\}$. For any $\gamma \in \mathcal{H}^{T,p}$ and for any theta-translate $\Theta_\alpha$ such that $p \not\in \Theta_\alpha$, the divisor $\Theta_\gamma + \Theta_\alpha$ contains $T$ and avoids $p$. This means that, for such $\alpha$’s, $p$ is not in the base locus of $|\mathcal{I}_T((2\Theta)_\alpha)|$. Thus $B(\mathcal{I}_T(2\Theta), p)$ is contained in $\bigcap_{\gamma \in \mathcal{H}^{T,p}} \Theta_{\gamma + p}$, which certainly has codimension $\geq 2$ (note that $\mathcal{H}^{T,p}$ has positive dimension and, since $\Theta$ is assumed to be irreducible, the intersection of any pair of distinct theta-translates has codimension 2). Using (6), the assertion follows by induction. 

Example 3.13. The above estimate is sharp for a collection of $g$ points lying on an Abel-Jacobi curve. Indeed, arguing as in Example 3.7, $n \leq g + 1$ points on an Abel-Jacobi curve $C$ impose independent conditions on $H^0(\mathcal{O}_A(2\Theta))$ away from a locus isomorphic to $W_{n-2}$. It seems likely that, under the hypothesis of the above Lemma, the more refined inequality $\dim V(\mathcal{I}_Y(2\Theta)) \leq n - 2$ holds.
4. The Castelnuovo-Schottky Lemma: statement and related results

4.1. The statement and some consequences. In this section we state the main result of the paper, Theorem \[\text{[A]}\]. Namely, we will characterize the extremal case of the bound on the number of conditions provided by Proposition \[\text{[3,6]}\].

**Definition 4.1** (Extremal position). A set of \( n \geq g + 1 \) distinct points \( \Gamma \subset A \) is in \textit{extremal position} if it is theta-general, and if it imposes precisely \( g + 1 \) conditions on \( H^0(\mathcal{O}((2\Theta)_{\alpha})) \) for general \( \alpha \in \hat{A} \). (Note that by semicontinuity \( \Gamma \) will impose at most \( g + 1 \) conditions on all 2-theta linear series.)

We will show that the existence of points in extremal position is intimately related to the existence of trisecants to the Kummer variety associated to \( A \), and in fact of a special positive-dimensional family of such. As a consequence, the well-known Gunning-Welters criterion will imply Theorem \[\text{[A]}\], which we restate here for convenience:

**Theorem 4.2.** Let \((A, \Theta)\) be an irreducible principally polarized abelian variety of dimension \( g \), and let \( \Gamma \) be a set of \( n \geq g + 2 \) points on \( A \) in extremal position. Then \((A, \Theta)\) is the canonically polarized Jacobian of a curve \( C \), and \( \Gamma \) is contained in a unique Abel-Jacobi embedding \( C \subset J(C) \).

Admitting Theorem \[\text{[1,2]}\] there is a natural way of recovering the curve \( C \) from the given data. (In particular this provides another proof of the Torelli theorem.)

**Corollary 4.3.** In the setting of Theorem \[\text{[1,2]}\], let \( U_\Gamma \subset \hat{A} \) be the open set of \( \alpha \in \hat{A} \) such that \( \Gamma \) imposes exactly \( g + 1 \) conditions on \( H^0(\mathcal{O}_A((2\Theta)_{\alpha})) \). Then, for any non-empty open subset \( U \subset U_\Gamma \), the Abel-Jacobi curve \( C \) is the (scheme-theoretic) intersection of all \( \mathcal{O}_A((2\Theta)_{\alpha}) \) with \( \alpha \in U \).

**Proof.** If \( \alpha \in U_\Gamma \), then \( H^0(\mathcal{I}_\Gamma((2\Theta)_{\alpha})) = H^0(\mathcal{I}_C((2\Theta)_{\alpha})) \). The statement follows then immediately from Corollary 4.2 of \[\text{[PP1]}\], which says that the sheaf \( \mathcal{I}_C(2\Theta) \) is \textit{continuously globally generated}, i.e. for any open set \( U \subset \hat{A} \) the evaluation map

\[
\bigoplus_{\alpha \in U} H^0(\mathcal{I}_C((2\Theta)_{\alpha})) \otimes \alpha^\vee \to \mathcal{I}_C(2\Theta)
\]

is surjective. \(\square\)

As another consequence, we have a similar Schottky-type criterion based on conditions imposed on higher order theta functions.

**Corollary 4.4.** Let \((A, \Theta)\) be an irreducible principally polarized abelian variety of dimension \( g \), and let \( \Gamma \) be a theta-general set on \( A \). Assume that there is an integer \( k \geq 2 \) such that \( |\Gamma| > (k-1)g+1 \), and that \( \Gamma \) imposes exactly \((k-1)g+1\) conditions on \( H^0(\mathcal{O}_A(k\Theta_{\alpha})) \) for general \( \alpha \in \hat{A} \). Then \((A, \Theta)\) is the canonically polarized Jacobian of a curve \( C \), and \( \Gamma \) is contained in a unique Abel-Jacobi embedding \( C \subset J(C) \). If \( k \geq 3 \), given any \( \alpha \in \hat{A} \) such that \( \Gamma \) imposes \((k-1)g+1\) conditions on \( H^0(\mathcal{O}_A(k\Theta_{\alpha})) \), then \( C \) is the base locus of \(|\mathcal{I}_\Gamma(k\Theta_{\alpha})|\).

**Proof.** For \( k = 2 \) this is just Theorem \[\text{[1,2]}\]. If \( k > 2 \), we claim that the hypothesis implies that any subset \( X \subset \Gamma \) such that \( |X| = |\Gamma|-(k-2)g \) is in extremal position. The statement will then follow from Theorem \[\text{[1,2]}\]. To prove the claim, we may assume that \( |\Gamma| = (k-1)g+2 \), so that \( |X| = g+2 \). If \( X \) is not in extremal position, i.e. if \( X \) imposes independent conditions on \( H^0(\mathcal{O}_A((2\Theta)_{\alpha})) \) for general \( \alpha \in \hat{A} \), then for any \( p \in X \) and for general \( \alpha \in \hat{A} \), there is a divisor \( D_{\alpha,p} \in \mathcal{O}_A((2\Theta)_{\alpha}) \) such
Lemma/Notation 5.1. Let \( D_{\alpha,p} \) contains \( X - \{p\} \) and avoids \( p \). We decompose \( \Gamma \) as \( \Gamma = (X - \{p\}) \cup Y_1 \cup \ldots \cup Y_{k-2} \cup \{p\} \), with \( |Y_i| = g \). For any \( i \) we choose a theta-translate \( \Theta_{\gamma_i,p} \) containing \( Y_i \) and avoiding \( p \). Then \( D_{\alpha,p} + \Theta_{\gamma_1,p} + \ldots + \Theta_{\gamma_{k-2},p} \subseteq |(k\Theta)_\alpha + \sum \gamma_i| \) is a divisor containing \( \Gamma - \{p\} \) and avoiding \( p \). Since \( \alpha \) varies in a Zariski-open set of \( \hat{A} \), \( \alpha + \sum \gamma_i \) also does. As this can be done for any \( p \in \Gamma \), it follows that \( \Gamma \) imposes independent conditions on \( H^0(\mathcal{O}((k\Theta)_\beta)) \), for \( \beta \) general in \( \hat{A} \). The proof is completed.

4.2. Relationship with [Gr1]. After completing a first draft of this manuscript, we were informed by Sam Grushevsky that his paper [Gr1] contains a result proved via the analytic theory of theta functions (and which is used for finding equations for the locus of hyperelliptic Jacobians), whose statement is similar to that of Theorem 4.2. The statement initially formulated in [Gr1] was unfortunately not correct, since the hypothesis was too weak. However recently the author has informed us of a correction, which will appear in an erratum [Gr2]. The revised statement is the following:

**Theorem 4.5.** ([Gr2]) Let \((A, \Theta)\) be an irreducible ppav of dimension \( g \), and \( A_0, \ldots, A_{g+1} \) distinct points on \( A \). Denote by \( K \) the Kummer map associated to \(|2\Theta|\), and suppose that for every \( z \in A \), the images \( K(A_i + z) \) are linearly dependent. Assume moreover that there exist some \( k \) and \( l \) such that for \( y := -\frac{A_i + A_j}{2} \) the linear span of the points \( K(A_i + y) \) is of dimension precisely \( g + 1 \). Then \( A \) is the Jacobian of some curve \( C \), and all the points \( A_i \) belong to an Abel-Jacobi embedding of \( C \).

Half of the hypothesis of both this result and Theorem 4.2 is the same, and it would be very interesting to discover a direct relationship between the two complete hypotheses.

5. Proof of the Castelnuovo-Schottky Lemma

5.1. Analysis of loci of linear dependence for points in extremal position. From this point on, unless otherwise stated, \((A, \Theta)\) will be assumed to be an irreducible ppav. The following result is the key property satisfied by sets of points in extremal position in an irreducible ppav.

**Lemma/Notation 5.1.** Let \( \Gamma \) be a collection of \( n \geq g + 2 \) points in extremal position on \( A \), and let \( Y \subseteq \Gamma \) be any subset consisting of \( g \) points. Then:

1. For any \( s \in \Gamma - Y \), there is a unique theta-translate \( \Theta_{\gamma_Y} \) containing \( \Gamma \) and avoiding \( s \). Moreover, this theta-translate works for any \( s \in \Gamma - Y \). Hence \( \Theta_{\gamma_Y} \cap \Gamma = Y \).
2. For any subset \( Z \subseteq \Gamma \) consisting of \( g + 1 \) points, the linear dependence locus \( V(I_Z(2\Theta)) \) is a theta-translate, denoted \( \Theta_{\alpha_Z} \).
3. In the setting of (2), if \( Z = Y \cup \{p\} \), then \( \gamma_Y + p = \alpha_Z \).
4. If \( T \subseteq \Gamma \) is a collection of \( g - 1 \) points and \( p, q \in \Gamma - T \), then \( \gamma_T \cup \{p\} = q = \gamma_T \cup \{q\} + p \).

**Proof.** Without loss of generality, we can assume that \( |\Gamma| = g + 2 \). We choose two points \( p, q \in \Gamma \) and write \( \Gamma = Y \cup \{p, q\}, \ Z := Y \cup \{p\} \). For any \( \gamma \in \mathcal{H}^Y \) and for any \( \beta \in \Theta_p - (\Theta_p \cap \Theta_q) \), the divisor \( \Theta_\gamma \cap \Theta_\beta \) contains \( Z \) and misses \( q \). Therefore, since we are assuming that for any \( \alpha \in \hat{A} \) the set \( \Gamma \) fails to impose independent conditions on \(|(2\Theta)_\alpha|\), we must have that \( \Theta_{\gamma + p} - (\Theta_\gamma \cap \Theta_{\gamma + q}) \) is contained in the subvariety \( V(I_Z(2\Theta)) \). Since \( \Theta \) assumed to be irreducible, this gives

\[
\Theta_{\gamma + p} \subseteq V(I_Z(2\Theta))
\]
for any $\gamma \in \mathcal{H}^{Y,q}$. On the other hand, for any $\gamma' \in \mathcal{H}^{Y,p}$ and $\beta \notin \Theta_p$, the divisor $\Theta_{\gamma'} + \Theta_{\beta}$ contains $Y$ and avoids $p$. Hence

$$B(I_Y(2\Theta), p) \subset \Theta_{\gamma' + p}.$$  

In conclusion, for any $p \in T$, it follows from (1) that

$$\Theta_{\gamma + p} \subset V(I_Z(2\Theta)) \subset B(I_Y(2\Theta), p) \cup V(I_Y(2\Theta)) \subset \Theta_{\gamma' + p} \cup V(I_Y(2\Theta))$$

Since, by Lemma 3.12, $\dim V(I_Y(2\Theta)) \leq g - 2$, we get that $\gamma = \gamma'$; i.e. that $\mathcal{H}^{Y,p}$ and $\mathcal{H}^{Y,q}$ consist of the same unique point $\gamma_Y$. Moreover $B(I_Y(2\Theta), p)$ is equal to $\Theta_{\gamma + p}$ and it is the unique divisor contained in $V(I_Z(2\Theta))$. Thus the fact that $V(I_T(2\Theta)) = \Theta_{\gamma + p}$ follows from (2). We have proved the first three points. Finally, (4) follows immediately from (3). \hfill \Box

5.2. Existence of trisecants and proof of the Theorem. Let $k$ be the projective map $A \to \mathbf{P}(H^0(\mathcal{O}_A(2\Theta))^\vee)$. Its image $k(A)$ is the Kummer variety of $A$. The relation between points in extremal position and trisecants to $k(A)$ is expressed by the following:

**Theorem 5.2.** Let $\Gamma \subset A$ be a collection of $g + 2$ points in extremal position. Let $p, q, s$ be three points in $\Gamma$, and write $\Gamma = T \cup \{p, q, s\}$ (hence $|T| = g - 1$). Then, for any $\alpha \in \mathcal{H}^{T,s}$, we have that

$$\Theta \cap \Theta_{p - q} \subset \Theta_{p - s} \cup \Theta_{\alpha + s - q - \gamma_{T \cup \{s\}}}.$$  

(See Lemma 5.1, for the definition of $\gamma_{T \cup \{s\}}$.) Equivalently, for any $\xi \in \frac{1}{2}\mathcal{H}^{T,s}_{p - q - \gamma_{T \cup \{s\}}}$, the points $k(\xi)$, $k(\xi - (p - q))$, and $k(\xi - (p - s))$ lie on a line.

**Proof.** The equivalence between the second assertion and the first is well known (cf. e.g. [14] p.80 or [15] p.104-105). For the first assertion, let us fix $p, q, s \in \Gamma$. Combining Lemma 3.11 applied to $T \cup \{p, q\}$ and $T \cup \{q, s\}$, and Lemma 5.1 we have that

$$(3) \quad \Theta_{\gamma_{T \cup \{s\}} + p} \cap \Theta_{\gamma_{T \cup \{s\}} + q} = V_2(I_T(2\Theta)) \cup V(I_{T \cup \{s\}}(2\Theta)).$$

To begin with, we analyze the last subvariety appearing on the right hand side of (3). For any $\alpha \in \mathcal{H}^{T,s}$ and for any $\beta \notin \Theta_s$, the divisor $\Theta_{\alpha} + \Theta_{\beta}$ contains $T$ and avoids $s$. Therefore, as in Lemma 3.12 we get

$$B(I_T(2\Theta), s) \subset \bigcap_{\alpha \in \mathcal{H}^{T,s}} \Theta_{\alpha + s}.$$  

Hence, by (1) of §4,

$$V(I_{T \cup \{s\}}(2\Theta)) \subset \left( \bigcap_{\alpha \in \mathcal{H}^{T,s}} \Theta_{\alpha + s} \right) \cup V(I_T(2\Theta)).$$

Clearly $V(I_T(2\Theta)) \subset V(I_{T \backslash \{s\}}(2\Theta))$. Therefore

$$(4) \quad V(I_{T \cup \{s\}}(2\Theta)) \subset \left( \bigcap_{\alpha \in \mathcal{H}^{T,s}} \Theta_{\alpha + s} \right) \cup V(I_{T \backslash \{s\}}(2\Theta)).$$

Now we turn our attention to the first subvariety of the right hand side of (3). For any point $r \in \Gamma$ we have $V_2(I_T(2\Theta)) \subset V(I_{T \backslash \{r\}}(2\Theta))$. In particular

$$V_2(I_T(2\Theta)) \subset V(I_{T \backslash \{s\}}(2\Theta))$$

Putting together with (1) it turns out that, for any $\alpha \in \mathcal{H}^{T,s}$,

$$(5) \quad \Theta_{\gamma_{T \cup \{s\}} + p} \cap \Theta_{\gamma_{T \cup \{s\}} + q} \subset V(I_{T \backslash \{s\}}(2\Theta)) \cup \Theta_{\alpha + s}.$$  

To conclude the proof, note that, for any $r \in \Gamma$, $V(I_{T \backslash \{r\}}(2\Theta)) = \Theta_{\alpha_{T \backslash \{r\}}}$ for any $r \in \Gamma$ (Lemma 5.1). If $p \neq r$, we can write

$$\alpha_{T \backslash \{r\}} = \gamma_{T \cup \{s\}} + p + q - r,$$
since by Lemma 5.1 we have that $\alpha_{T-r} = \gamma_{T-p} + p$ and $\gamma_{T-p} + r = \gamma_{T-q} + q = \alpha_{T-p}$ (note that $\Gamma - \{p, q\} = T \cup \{s\}$). In conclusion, for any $r \in \Gamma$,

\begin{equation}
V(T-r)(2\Theta) = \Theta_{\gamma_{T\cup\{s\}}} + p + q - r.
\end{equation}

Plugging this for $r = s$ into (5) we get that, for any $\alpha \in \mathcal{H}_{T,s}$

$$\Theta_{\gamma_{T\cup\{s\}}} + p \cap \Theta_{\gamma_{T\cup\{s\}}} + q \subset \Theta_{\gamma_{T\cup\{s\}}} + p + q - s \cup \Theta_{\alpha + s},$$

The statement follows by translating by $-\gamma_{T\cup\{s\}} - q$. \qed 

Now can finally put everything together in order to prove our Castelnuovo-Schottky Lemma for abelian varieties.

**Proof.** (of Theorem A). We will use the following part of Welters’ criterion (building on previous work of Gunning [Gu]):

Let $a, b, c$ be three distinct points on an irreducible ppav $(A, \Theta)$. If the locus $W_{a, b, c}$ of $\xi \in A$ such that $k(2\xi + a), k(2\xi + b)$ and $k(2\xi + c)$ lie on a line in $\mathbb{P}(H^0(O_A(2\Theta)))$ is positive-dimensional, then $W_{a, b, c}$ is a smooth irreducible curve and $(A, \Theta)$ is the Jacobian of $W_{a, b, c}$. ([We2], Theorem (0.5), case (i); see also [B], p.104-105).

To prove Theorem A we fix three points $p, q, s \in \Gamma$ and we consider any subset $X$ of $\Gamma$, with $|X| = g + 2$, and containing $p, q, s$. We write $X = T \cup \{p, q, s\}$. Since $|T| = g - 1$, (every component of) $\mathcal{H}_{T,s}$ is positive-dimensional (see Definition/Notation 3.1). Therefore, by Theorem 5.2 and the Gunning-Welters criterion, we are on a Jacobian. It remains to prove that $\Gamma$ is contained in an Abelian-Jacobi curve. Note that it turns out that the closure $(\overline{\mathcal{H}_{T,s}})_{p-q-\gamma_{T\cup\{s\}}}$ coincides with $W_{p-q-p-s}$, hence it is a smooth irreducible curve and $(A, \Theta)$ is its polarized Jacobian. Moreover, it is easy to deduce (cf. e.g. [B], p.104-105) that $(\overline{\mathcal{H}_{T,s}})_{p-q-\gamma_{T\cup\{s\}}} = C_{p-q-s}$, for a fixed Abelian-Jacobi curve $C$ in $A = J(C)$. In particular, it follows that

$$(\overline{\mathcal{H}_{T,s}})_{\gamma_{T\cup\{s\}} - s} = C$$

does not depend on $s$ and $T$ but just on $p$ and $q$. By Lemma 5.1(4), $\gamma_{T\cup\{s\}} - s = \gamma_{T\cup\{t\}} - t$, so

$$\overline{\mathcal{H}_{T,s}} = C_{\gamma_{T\cup\{t\}} - t}.$$

Now if $t \in \Gamma$, $t \neq s$ then $\gamma_{T\cup\{t\}} \in \mathcal{H}_{T,s}$ (Remark 3.3). Hence $t \in C$. Therefore $\Gamma \subset C$. \qed 

6. Genus bound

As another application of this point of view, we prove Theorem B. This is a “Castelnuovo bound”, i.e. a bound on the genus of a curve on a $g$-dimensional ppav $(A, \Theta)$ in function of its degree $d := C \cdot \Theta$. The bound is quadratic in the degree, with leading term $d^2/2g$. Although the proof shows, somewhat subtly, that it is not optimal for $q \geq 3$, it is of the expected order of magnitude, and it improves considerably a previously known bound 4.

**Remark 6.1.** On abelian surfaces, i.e. for $g = 2$, the bound in Theorem B is optimal since for even $d = 2m$ it reads $\gamma \leq d^2/4 + 1$, which is the genus of smooth curves in $|m\Theta|$.

---

4 In [De1] Theorem 5.1, it is shown that the Castelnuovo bound for curves in projective space yields a quadratic bound for ppav’s whose leading term is $2d^2/(g - 1)$. 
6.1. General position of general theta-sections of an irreducible curve. To prove Theorem \[\text{[3]}\] we will follow Castelnuovo’s method based on the number of conditions imposed on hypersurfaces by a general hyperplane section of the curve \(C\) (\cite{ACGH}, p.114–115). The main point here is that, as soon as the degree is higher than \(g\), a general theta-section \(C \cap \Theta_{\alpha}\) is theta-general (Proposition \[\text{[6.0]}\]). Although we are able to prove this by means of a direct argument, we propose the following problem, which is interesting on its own sake.

Problem 6.2. Study the monodromy of the general theta-section of non-degenerate curves in irreducible ppav’s. (On general ppav’s it can be shown à la Harris – cf. \cite{ACGH} p.111 – that the monodromy of a general theta-section is always the symmetric group).

Here we will confine ourselves to a more elementary analysis, which will be enough for our purposes, and won’t tackle the problem above. Let \(C\) be a non-degenerate, reduced and irreducible curve on \(A\). Then it is well-known that there exists a non-empty open set \(U \subset \tilde{A}\) such that for any \(\alpha \in U\) the theta-translate \(\Theta_{\alpha}\) meets \(C\) transversally. We make a preliminary observation (borrowed from \cite{GH}, Lemma at p.249). Let \(U\) be the above open set. Denoting by \(C^{(d)}\) the symmetric product of \(C\), we have the map

\[
\phi : U \to C^{(d)}, \quad \beta \mapsto \Theta_{\beta} \cap C,
\]

whose image does not meet the diagonals. Since \(C\) is non-degenerate, \(\phi\) is finite. For a fixed \(\alpha \in U\), we put an order on \(\Theta_{\alpha} \cap C = \{p_1, \ldots, p_d\}\). Up to restricting \(U\), we can lift \(\phi\) to a map to the cartesian product \(\psi : U \to C^{d}\) such that, for \(\beta \in U\), \(\psi(\beta) = \{ (\Theta_{\beta} \cap C), \ldots, (\Theta_{\beta} \cap C)\}\). Fix \(k \leq g\). For any multi-index \(I = \{i_1, \ldots, i_k\}\), by composing with the corresponding projection, we get a map \(\pi_I : V \to C^k\). The following Lemma follows immediately.

**Lemma 6.3.** The maps \(\pi_I\) are dominant for any \(I\). Therefore, if \(\alpha\) is sufficiently general, any property satisfied by a general effective divisor of degree \(k \leq g\) on \(C\) is satisfied by any effective divisor \(Y\) of degree \(k\) contained in \(\Theta_{\alpha} \cap C\).

So far for uniformity properties of a general theta-section. Concerning theta-general position, we start with the following:

**Lemma 6.4.** Let \(C\) be a non-degenerate, reduced and irreducible curve of degree \(d > g\). Then a general divisor of degree \(g\) on \(C\) is contained in at least two distinct theta-sections.

**Proof.** To simplify the notation, we will prove the result assuming that \(C\) is smooth (the same argument works in the non-smooth case via passage to the normalization of \(C\)). Assume that the assertion is not true. Then one can associate to a general divisor of degree \(g\), say \(Y\), the linear equivalence class on \(C\) of the unique theta-section containing \(Y\). This induces a rational map \(f : C^{(g)} \to \text{Pic}^0(C)\). Now \(f\) has to factor through the Albanese map of \(C^{(g)}\), i.e. the Abel-Jacobi map \(C^{(g)} \to J(C)\). Let \(h\) be the induced (endo)morphism of abelian varieties \(h : J(C) \to \text{Pic}^0(C)\). Note that, by construction, all the \(Y\)'s contained in a given theta-section \(\Theta_{\alpha} \cap C\) are contained in a fiber of \(f\). Therefore, as we are assuming \(C \cdot \Theta > g\), we can choose two distinct divisors \(Y_1\) and \(Y_2\) both contained in \(\Theta_{\alpha} \cap C\), of the form \(Y_1 = p_1 + \ldots + p_{g-1} + p\) and \(Y_2 = p_1 + \ldots + p_{g-1} + q\). We have that \(h(p) - h(q) = f(Y_1) - f(Y_2) = 0\). Since this can be done for general \(p\) and \(q\) in \(C\), we would have that \(C\) is contracted by \(h\), i.e. that \(h\) is constant. This yields that \(f\) is constant, a contradiction. \(\square\)

**Remark 6.5.** The above Lemma provides another characterization of Jacobians and Abel-Jacobi curves: if there exists a non-degenerate curve \(C\) such that, given a collection \(Y\) of \(g\) general distinct points on \(C\), there is only one theta-translate containing \(Y\) and not containing
$C$, then the abelian variety $A$ is a Jacobian and $C$ is an Abelian-Jacobi curve. This follows at once from the previous Lemma and the Matsusaka-Ran criterion.

We are now in a position to prove the main technical result of this subsection.

**Proposition 6.6 (General position).** Let $C$ be a non-degenerate, reduced and irreducible curve of degree $d > g$ and let $X = \Theta_A \cap C$ be a general theta-section of $C$. Then $X$ is theta-general.

**Proof.** Given a divisor $Y \subset X$ such that deg$(Y) = g$, we denote by $W(Y)$ the locus of theta-translates containing $Y$. Moreover we denote $\phi(Y) := C \cap \bigcap_{\alpha \in W(Y)} \Theta_{\beta}$. By Proposition 6.3 the cardinality of $\phi(Y)$ is constant for all such $Y$, and we will denote it by $n$. By definition, the fact that $X$ is theta-general means that $Y = \phi(Y)$ for all $Y$, i.e. that $n = g$.

We make the following claim: let $Z$ be another divisor of degree $g$ contained in $X$. Then $\phi(Y) = \phi(Z)$ if and only if $Z \subset \phi(Y)$. If the converse implication were not true, then deg $\phi(Z) < \text{deg} \phi(Y)$, contradicting Proposition 6.3. The direct implication follows from the definition.

Let’s denote by $\mathcal{P}^j(X)$ the set of subsets of $X$ of cardinality $j$. We have produced a family $\Phi = \{\phi(Y)\}_{Y \in \mathcal{P}^g(X)} \subset \mathcal{P}^n(X)$ with the following property: for any $Y \in \mathcal{P}^g(X)$ there exists a unique $\phi \in \Phi$ containing $Y$. It follows easily that $\Phi$ falls into one of the following three cases: (1) $n = g$ and $\Phi = \mathcal{P}^g(X)$; (2) $g = 1$, $|X|$ is a multiple of $n$, and $\Phi$ is a partition of $X$ in subsets of cardinality $n$; (3) $n = |X|$ and $\Phi = \{X\}$. But case (2) is excluded since $g \geq 2$, and case (3) is excluded since, by Lemma 6.4, $n < |X|$. Therefore case (1) holds, and the Proposition is proved. \qed

### 6.2. Proof of the bound.

We are now ready for the proof of the genus bound. From this stage on, the argument (for the first part) is essentially that of Castelnuovo, as accounted e.g. in [ACGH], p.115.

**Proof.** (of Theorem 11). Let $\Theta_A$ be a fixed general theta-translate, so that $X = C \cap \Theta_A$ is theta-general. Let us denote by $\beta_l$ the generic value of the (affine) dimension of the linear series cut out by $|(l\Theta_A)|$ on $C$, with $\alpha \in \tilde{A}$. In other words, $\beta_l$ is the generic value of the difference

$$h^0(O_A(l\Theta_A)) - h^0(I_C((l\Theta_A))).$$

Taking $H^0$’s in the exact sequence

$$0 \to I_C((l-1)\Theta_A) \to I_C((l\Theta_A)) \to I_{X/\Theta}((l\Theta_A)) \to 0$$

shows, after an immediate computation, that for general $\alpha$ and for any $l \geq 1$, the difference $\beta_l - \beta_{l-1}$ is greater than or equal to the number of conditions imposed by $X$ on $H^0(\Theta_A, O_{\Theta_A}(l\Theta_A))$, which is in turn equal to the number of conditions imposed by $X$ on $H^0(O_A(l\Theta_A))$. Assume $\Delta > g$. By Proposition 6.6 $X$ is theta-general. Hence, by Proposition 3.1

$$\beta_l - \beta_{l-1} \geq \min\{d, (l-1)g + 1\}.$$  

Let $\pi : C' \to C$ be the birational morphism in the statement, and let us denote by $\lambda_h$ the generic value of $h^0(C', \pi^*O_C(h\Theta_A))$. It is clear that $\lambda_h \geq \beta_h$ for any $h$. Let $m := \left\lceil \frac{d-1}{g} \right\rceil$, so that

---

5Proof. We prove that if $n > g$ then either (2) or (3) hold. If $n = g + 1$, for any $Y \in \mathcal{P}^g(X)$ the residual set $r_Y = \phi(Y) - Y$ is a point. This establishes a map $r : \mathcal{P}(X) \to X$, $Y \mapsto r_Y$. By construction, the map $r$ is bijective. Therefore $|\mathcal{P}^g(X)| = |X|$ and the assertion follows. If $n > g + 1$, subtracting one point to any $\phi \in \Phi$, we get a new set $X'$, equipped with a family of subsets $\Phi' \subset \mathcal{P}^{n-1}(X')$ with the same property. Therefore the assertion follows easily by induction on $n$. 

\[ d - 1 = gm + \epsilon, \text{ with } 0 \leq \epsilon < g. \] By (8) it follows (noting that \( \beta_1 = 1 \)) that for any \( k \geq 0 \):

\[ \beta_{m+1+k} - 1 = \sum_{l=2}^{m+1+k} (\beta_l - \beta_{l-1}) \geq \sum_{l=1}^{m} (l + 1) + kd = \left( \frac{m + 1}{2} \right) g + m + kd. \]

But, for \( k \) sufficiently big, \( h^1(C', \pi^*O_C((m + 1 + k)\Theta)) \) vanishes. Therefore, by Riemann-Roch on \( C' \):

\[ (m + 1)d - \gamma + 1 + kd = \lambda_{m+1+k} \geq \beta_{m+1+k} \geq \left( \frac{m + 1}{2} \right) g + m + 1 + kd. \]

The inequality of the statement follows.

To prove the last part note that, if equality is attained by a certain curve \( C \) in \( A \), then for any \( \ell \geq 2 \) we must have (using (7) again)

\[ \beta_l - \beta_{l-1} = h^0(O_A((l\Theta)_{\alpha})) - h^0(I_X((l\Theta)_{\alpha})) = \min\{d, (l - 1)g + 1\} \]

for \( \alpha \) general in \( \hat{A} \). From the first equality in (11) it follows easily that if a curve \( C \) attains equality, then

\[ h^1(I_X((l-1)\Theta_{\alpha})) = 0 \]

for any \( \ell \geq 2 \) and for general \( \alpha \in \hat{A} \). Given a Zariski-open set \( U \subset \hat{A} \), we denote by \( S_{l,U} \) (resp. \( \Gamma_{l,U} \)) the intersection of all \( Q_\alpha \in \mathcal{I}_C(((l+1)\Theta)_{\alpha}) \) (resp. the intersection of all \( E_\alpha \in \mathcal{I}_X(((l + 1)\Theta)_{\alpha+\hat{\alpha}}) \)), for \( \alpha \in U \). From the exact sequence (7) and from (12) it follows that, for a suitable \( U \subset \hat{A}, \Gamma_{l,U} = S_{l,U} \cap \Theta_{\hat{\alpha}} \). But if \( d \geq (l - 1)g + 2 \), Theorem 4.2 and Corollaries 4.3 and 4.4 together with the second equality in (11), yield that \( A \) is a Jacobian and \( \Gamma_{l,U} \) is an Abel-Jacobi curve. This would imply that \( S_{l,U} \) is a surface whose generic theta-section is an Abel-Jacobi curve, which is impossible if \( g \geq 3 \). In conclusion, (12) must fail for any \( \ell \geq 2 \) such that \( (l - 1)g + 1 < d \). Therefore (11) must fail for at least one \( \ell \), so there is strict inequality in the genus bound.

7. Appendix: The divisor class associated to points failing to impose independent conditions

In Proposition 5.1 it is shown, by elementary methods, that given a collection \( \Gamma \) of \( g + 2 \) or more points in extremal position then, for any subset \( Z \subset \Gamma \) with \( |Z| = g + 1 \), the locus \( V(\mathcal{I}_Z(2\Theta)) \) is a divisor (in fact a specific theta-translate). This is a key point in the proof of Theorem A. It turns out that a weaker version of this statement holds in great generality. The proof uses the \( M \)-regularity criterion (cf. [PPT]).

Let \( A \) be an abelian variety, \( D \) an ample divisor, and \( Z \) a finite set on \( A \). Recall that we denote

\[ V(\mathcal{I}_Z(D)) := \{ \alpha \in \hat{A} \mid h^1(I_Z(D_\alpha)) > 0 \}. \]

**Proposition 7.1.** Let \( \Gamma \) be a collection of distinct points on \( A \). Let \( n(\Gamma) \) be the number of conditions generically imposed by \( \Gamma \) on \( H^0(O_A(D_\alpha)) \). Assume that \( n(\Gamma) < |\Gamma| \) and let \( Z \subset \Gamma \) be a subset of \( n(\Gamma) \) points generically imposing independent conditions on \( H^0(O_A(D_\alpha)) \). Then \( V(\mathcal{I}_Z(D)) \) is a proper closed subset of \( \hat{A} \), containing at least one divisorial component.

**Proof.** The fact that \( V(\mathcal{I}_Z(D)) \) is a proper subvariety of \( \hat{A} \) follows by definition. To prove that it contains a codimension one component, we note that since \( Z \) is finite and \( D \) is ample, \( h^i(\mathcal{I}_Z(D_\alpha)) = 0 \) for all \( i \geq 2 \) and all \( \alpha \in \hat{A} \). Therefore \( \mathcal{I}_Z(D) \) is an \( M \)-regular sheaf if and only
if codim_{\hat{A}}^{}V(I_Z(D)) \geq 2 (cf. [PP1] \S 2). If this is the case, the M-regularity criterion (Corollary 4.2 of loc. cit.) yields that I_Z(D) is continuously globally generated. This means that, for any open set U \subset \hat{A} the evaluation map

$$\bigoplus_{\alpha \in U} H^0(I_Z(D_\alpha)) \otimes \alpha^V \to H^0(I_Z(D))$$

is surjective. It follows immediately that, if codim_{\hat{A}}^{}V(I_Z(D)) \geq 2, then for \alpha general in \hat{A} there is no subscheme \Gamma containing \hat{Z} strictly and such that $H^0(I_Z(D_\alpha)) = H^0(I_{\Gamma}(D_\alpha))$. □

Assume that a subset \Gamma as in the previous Proposition is in a sufficiently uniform position (we won’t give a precise definition here). Then, for any subset Z \subset \Gamma with |Z| = n(\Gamma), the subvarieties $V(I_Z(D_\alpha))$ are proper and the algebraic equivalence classes of their divisorial part coincide. It is possible that the divisorial parts of the $V(I_Z(D_\alpha))$’s have common components. We call the class the remaining components the (mobile) divisorial class of \Gamma. If \Gamma is a general subset of points on a curve C, the divisorial class of \Gamma is related to C.

**Example 7.2.** Let (A, Z) be ppav and let C curve in A such that: (a) $h^1(I_C((lZ)_\alpha)) = 0$ for \alpha general in \hat{A}, (b) $h^1(O_C((lZ)_\alpha)) = 0$ outside a subvariety of codimension at least two in \hat{A}. In the previous notation, take D = lZ. Let \Gamma be a general effective divisor on C, of sufficiently high degree, so that $h^0(O_C((lZ)_\alpha - \Gamma)) = 0$. Then, using (a), $n(\Gamma) = h^0(O_C(lZ)) = l \cdot d(C) - g(C) + 1$. Let Z \subset \Gamma be a general divisor of degree $n(\Gamma)$ and let $\Theta_Z$ be the theta-translate (in the Jacobian of C) given by $\{ \beta \in \text{Pic}^0(C) \mid h^1(O_C((lZ)_\alpha - Z) > 0 \}$ (we have $lZ \cdot C - n(\Gamma) = g(C) - 1$). We consider the map $\pi : \hat{A} \to \text{Pic}^0(C)$. We have the exact sequence

$$H^1(I_C((lZ)_\alpha)) \to H^1(I_Z((lZ)_\alpha)) \to H^1(O_C((lZ)_\alpha - Z)) \to H^2(I_C((lZ)_\alpha))$$

Since $H^2(I_C((lZ)_\alpha)) \cong H^1(O_C((lZ)_\alpha))$, (b) ensures that, regarding divisorial components of $V(I_Z(lZ))$, the last term of (13) is neglectable. Moreover (13) yields that the divisorial part of $V(I_Z(lZ))$ is $\pi^*\Theta_Z$, plus a (possibly empty) fixed divisor contained in $V(I_C(lZ)) = \{ \alpha \in \hat{A} \mid h^1(I_C((l\Theta)_\alpha) > 0 \}$. Thus the (mobile) divisorial class of \Gamma is $\pi^*[\Theta]$. For example, let $\tilde{C}$ be an Abel-Prym curve in a Prym variety, and $l = 2$. As E. Izadi informs us, it can be deduced from [K-S] that $h^1(I_{\tilde{C}}((2Z)_\alpha)$ vanishes for general $\alpha \in \hat{A}$. Hence (a) holds, while (b) holds trivially. Therefore the divisorial class of a general such $\Gamma \subset \tilde{C}$ is $2[\tilde{Z}]$.

We believe that, in view of possible extensions of the Castelnuovo-Schottky Lemma as in \S 2, the consideration of the divisor class is crucial. To start with, given an irreducible ppav $(A, \Theta)$, it would be interesting to know a lower bound for the number $n(\Gamma)$ of a uniform, theta-general collection $\Gamma$ with associated class $n[\Theta]$ (cf. the end of \S 2 above for a conjecture in the case $n = 2$).
