(Received 19 October 1995)

Abstract

Semiunitary transformation is applied to discuss supersymmetrization of cold Rydberg atoms. In the limit of vanishing kinetic energy the lowest angular momentum of the supersymmetric cold Rydberg atom is \(3\hbar/2\). A possible experimental verification is suggested. [S0031-9007(96)00109-3]

PACS numbers: 32.80.Rm, 11.30.Pb
Recently Baxter [1] showed that cold Rydberg atoms can play an interesting role of realizable analogs of Chern-Simons theory [2, 3]. By choosing an atomic dipole of a cold Rydberg atom in electric and magnetic field, and by an appropriate experimental arrangement the motion of the dipole is constrained to be planar and rotationally symmetric, the Rötgens interaction takes on the form of a Chern-Simons term [3]. By placing the dipole in a strong magnetic field and in an appropriate optical trapping field, the elimination of the kinetic energy term in the Lagrangian could be achieved physically and Baxter [1] showed that the canonical angular momentum spectrum changes from one consisting of integers to one consisting of positive half integers; thus in principle an experimental verification of the Chern-Simons feature of fractional angular momentum is allowed.

Reference [4] showed evidence for a phenomenological supersymmetry in atomic physics. In \textit{SS QM} the term supersymmetry has nothing to do with spins at all, its meaning is just as that \textit{SS QM} is represented by a pair of bosonic Hamiltonians $H_-$ and $H_+$ which are superpartners of the \textit{SS} Hamiltonian $H_s = H_- + H_+$, and \textit{SS} charge $Q_s, Q_s^\dagger$, and $H_s$ satisfy \textit{SS} algebra [5].

In \textit{SS QM} the form of the problem must be truly one dimensional. For the one-dimensional system there is no room to define the angular momentum; one cannot discuss the relation of spectra of angular momenta between the system and its superpartner. For the case of two-dimensional Rydberg atoms angular momentum can be defined as an exterior product. This system can be reduced into two uncoupled one-dimensional systems, thus the supersymmetrization of its Hamiltonian and angular momentum can be simultaneously performed by a semiunitary transformation (\textit{SUT}) which will be defined later. This for the first time allows in principle a verification of the relation of spectra of angular momentum between a system and its superpartner. The results show that in the limit of vanishing kinetic energy the angular momentum spectrum of the \textit{SS} cold Rydberg atom changes from one consisting of integers to one consisting of positive half integers, with the lowest angular momentum $3\hbar/2$; \textit{SUT} destroys the lowest angular momentum state with $\hbar/2$ of the cold Rydberg atom.

\textit{Cold Rydberg atom}.—The Lagrangian of the cold Rydberg atom with an atomic dipole
\[ L = \frac{1}{2} M \ddot{R}_i \dot{R}_i + \frac{1}{2} g \epsilon_{ij} R_i \dot{R}_j - \frac{1}{2} K R_i R_i. \]  

(1)

where \( M \) is the mass of the dipole, the electric field \( \vec{E} \) acts radially in the \( x - y \) plane, \( E_i \sim -R_i \) (\( i = 1, 2 \)), and the constant magnetic field \( \vec{B} \) aligns the \( z \) axis. The constant parameters \( g \) and \( K \) are proportional to the magnitude of the dipole moment and, respectively, magnetic and electric field dependent. \( \epsilon_{12} = -\epsilon_{21} = 1; \epsilon_{11} = \epsilon_{22} = 0 \). In (1) the second term \( \frac{1}{2} g \epsilon_{ij} R_i \dot{R}_j \) takes on the form of the Chern-Simons interaction. The Hamiltonian obtained from (1) is

\[ H = \frac{1}{2M} \left\{ p_i + \frac{g}{2} \epsilon_{ij} R_j \right\}^2 + \frac{K}{2} R_i R_i + \frac{1}{2M} g \epsilon_{ij} P_i R_j + \frac{1}{2} M \Omega^2 R_i R_i, \]

(2)

where the canonical momentum \( P_i = M \dot{R}_i - \frac{g}{2} \epsilon_{ij} R_j \), and the frequency

\[ \Omega = \left( \frac{g^2}{4M^2} + \frac{K}{M} \right)^{1/2}. \]

(3)

In (3) the dispersive mass term \( g/2M \) comes from the presence of the Chern-Simons term. By changing the variables \( R_i, P_i \) to

\[ X_a = (M \Omega/2\omega_a)^{1/2} R_1 - (1/2M \Omega \omega_a)^{1/2} P_2, \]
\[ X_b = (M \Omega/2\omega_b)^{1/2} R_1 + (1/2M \Omega \omega_b)^{1/2} P_2, \]

(4a)

\[ P_a = (\omega_a/2M \Omega)^{1/2} P_1 + (M \Omega \omega_a/2)^{1/2} R_2, \]
\[ P_b = (\omega_b/2M \Omega)^{1/2} P_1 - (M \Omega \omega_b/2)^{1/2} R_2 \]

(4b)

where

\[ \omega_a = \Omega + g/2M, \omega_b = \Omega - g/2M, \]

(5)

the Hamiltonian is rewritten in the form of two uncoupled harmonic oscillators of unit mass and of frequencies \( \omega_a \) and \( \omega_b \). Define

\[ A_\alpha = (\hbar/2\omega_\alpha)^{1/2} d/dX_\alpha + (\omega_\alpha/2\hbar)^{1/2} X_\alpha, \]
\[ A_\alpha^\dagger = - (\hbar/2\omega_\alpha)^{1/2} d/dX_\alpha + (\omega_\alpha/2\hbar)^{1/2} X_\alpha \quad (\alpha = a, b); \]

(6)

3
the Hamiltonian (2) becomes

$$H = H_a + H_b, \quad H_\alpha = \hbar \omega_\alpha \left( A^\dagger_\alpha A_\alpha + \frac{1}{2} \right) \quad (\alpha = a, b).$$

(7)

If $|n_\alpha\rangle$ is an eigenfunction of $H_\alpha$ with eigenvalue $E_{n_\alpha} = \hbar \omega_\alpha (n_\alpha + 1/2)$ $(\alpha = a, b)$, $|n_a, n_b\rangle = |n_a\rangle |n_b\rangle$ is an eigenfunction of $H$ with eigenvalue

$$E_{n_a, n_b} = \hbar \omega_a (n_a + 1/2) + \hbar \omega_b (n_b + 1/2) \quad (n_a, n_b = 0, 1, 2, \ldots),$$

(8)

In two dimensions the canonical angular momentum is defined as an exterior product

$$J = \epsilon_{ij} R_i P_j = J_a - J_b, \quad J_\alpha = \hbar (A^\dagger_\alpha A_\alpha + \frac{1}{2}) \quad (\alpha = a, b).$$

(9)

Because $[H, J] = 0$, $J$ is a constant of motion, and $J$ and $H$ have common eigenfunctions $|n_a, n_b\rangle$. Notice that $J_a$ and $J_b$ have zero-point angular momentum $\hbar/2$. Because of the cancellation of $\hbar/2$ between modes $a$ and $b$, the eigenvalues of $J$ are integer multiples of $\hbar$,

$$j_{n_a, n_b} = \hbar (n_a - n_b) \quad (n_a, n_b = 0, 1, 2, \ldots).$$

(10)

**SS QM.** In one-dimensional SS QM a quantum system is described by a pair of related bosonic Hamiltonians $H_-$ and $H_+$ [5]:

$$H_\pm = -\frac{\hbar^2}{2} \frac{d^2}{dx^2} + V_\pm(x).$$

(11)

Suppose the ground-state wave function $\psi_0^{-}(x) \equiv \psi_0(x)$ of $H^{-}\equiv H_-$ is known, consider only unbroken supersymmetry corresponding to a normalizable ground state $\psi_0$ and adjust the ground-state energy $E_0^{-} = 0$. Introducing the superpotential $W(x) = -(h/\sqrt{2})\psi_0'/\psi_0$ (a prime denotes $d/dx$), we have $V_\pm(x) = W^2(x) \pm (1/\sqrt{2})W'(x)$. The Hamiltonians $H_\pm$ can be factorized as

$$H_- = A^\dagger A, \quad H_+ = AA^\dagger,$$

(12)

where

$$A = \frac{\hbar}{\sqrt{2}} \frac{d}{dx} + W(x), \quad A^\dagger = -\frac{\hbar}{\sqrt{2}} \frac{d}{dx} + W(x), \quad [A, A^\dagger] = \sqrt{2}\hbar W'(x).$$

(13)
The eigenfunctions $\psi_n^-$ and $\psi_n^+$ of $H_-$ and $H_+$, respectively, with eigenvalues $E_n^-$ and $E_n^+$ are related by

$$E_n^{(+) = E_{n+1}^{(-),}}$$

$$\psi_n^{(+)= A^{-1/2}_{n+1}} E_{n+1}^{(-)} A \psi_{n+1}^{(-)} \quad (n = 0, 1, 2, \ldots).$$

We find that the superpartner Hamiltonians $H_-$ and $H_+$ can be related by a SUT [6]. Consider the operator $AA^\dagger$. Because $AA^\dagger \psi_{n}^{(+) = E_{n}^{(+)}} \psi_{n}^{(+) = E_{n}^{(+)}}$, $E_{n}^{(+) > 0}$ ($n = 0, 1, 2, \ldots$), $AA^\dagger$ is positive definite, we can define

$$U = (AA^\dagger)^{-1/2} A, \quad U^\dagger = A^\dagger (AA^\dagger)^{-1/2},$$

$U$ and $U^\dagger$ satisfy

$$UU^\dagger = I, \quad U^\dagger U = A^\dagger (AA^\dagger)^{-1} A \equiv Q.$$  

Notice that $A^\dagger A \psi_n^{(-) = E_n^{(-)} \psi_n^{(-)}}, E_0^{(-) = 0}, E_n^{(-) > 0}$ for $n \geq 1$, so $A^\dagger A$ is semipositive definite and $(A^\dagger A)^{-1}$ is singular. Thus we cannot use the operator identities $f(AA^\dagger)A = A f(A^\dagger A)$, and $A^\dagger f(AA^\dagger) = f(A^\dagger A)A^\dagger$; the operator $Q$ defined in (16) is not a unit operator. The operator $U$ defined in (15) which satisfies (16) is called semiunitary [7]. Under this SUT $H_-$ is transformed into $H_+$,

$$H_+ = U H_- U^\dagger.$$  

Correspondingly, $\psi_n^{(-)}$ is transformed into $U \psi_n^{(-)}$. Notice that $U \psi_0 = 0$, $U \psi_{n+1}^{(-) = [E_{n+1}^{(-)}]^{-1/2} A \psi_{n+1}^{(-)},}$ with eigenvalues $E_n^{(+)} = E_{n+1}^{(-)}$ ($n = 0, 1, 2, \ldots$). The ground energy $E_{0}^{(+)} = E_{1}^{(-)}> 0$; here $E_{0}^{(-)} = 0$ disappears in the spectrum of $H_+$. Thus the SUT transforms the ($-$) system into its superpartner system ($+$), which fully covers the results of SS QM.

The operator $Q$ defined in (16) satisfies

$$Q^2 = Q, \quad [Q, H_-] = 0.$$  

$Q$ is a projection operator, and its eigenvalues $q$ ($q = 0, 1$) are good quantum numbers. $Q$ and $H_-$ have common eigenfunctions. Because $Q \psi_0 = 0$, $Q \psi_{n+1}^{(-) = \psi_{n+1}^{(-)}},$ we denote
\(|\psi_0\rangle = |0, 0\rangle, \ |\psi_{n+1}^{(-)}\rangle = |n + 1, 1\rangle \ (n = 0, 1, 2, \ldots)\), which are common eigenstates of \(H_-\) and \(Q\). The Hilbert space \(\mathcal{H}\) is divided into two subspaces \(\mathcal{H}_0\) and \(\mathcal{H}_1\), consisting of eigenstates |0, 0\rangle and |n + 1, 1\rangle with, respectively, eigenvalues \(q = 0\) and \(1\), \(\mathcal{H} = \mathcal{H}_0 \oplus \mathcal{H}_1\). In the basis |0, 0\rangle and |n + 1, 1\rangle \(Q = I - |0, 0\rangle\langle 0, 0|\), thus in the \(\mathcal{H}_1\) subspace the operator \(Q\) reduces to a unit operator and the \(SUT\) reduces to a unitary transformation.

Now we compare a unitary transformation and a \(SUT\). In quantum mechanics a unitary operator maintains all the physical properties of a quantum system. The situation is different for \(SUT\). The main reason is that \(SUT\) is a singular operator which readily appears in the structure of the projector \(Q\) defined in (16). Because of such singularities, \(SUT\) only partly maintains physical properties of the \((-)\) system. For example, it maintains the complete relation of \(\psi_n^{(-)}\), but does not maintain the orthogonality and normalization of \(\psi_n^{(-)}\), and only partly maintains the eigenvalues of \(H_-\). However, in the subspace \(\mathcal{H}_1\) the \(SUT\) behaves just like a unitary transformation. \(SUT\) transforms the \((-)\) system defined in the full Hilbert space \(\mathcal{H}\) into the \((+)\) system defined in the subspace \(\mathcal{H}_1\), destroys the ground state of \(H_-\), but maintains all other physical properties of the \((-)\) system in the subspace \(\mathcal{H}_1\). This explains the legitimacy of the applications of \(SUT\) to \(SS QM\).

*Supersymmetrization of cold Rydberg atoms.* – Using \(SUT\) we can thoroughly study the supersymmetrization of cold Rydberg atoms. The Hamiltonian (7) has two modes \(a\) and \(b\). We define the potential \(V^{(-)}(X) = \sum_{\alpha=a,b} (\frac{1}{2} \omega^2 \alpha X^2 - \frac{1}{2} \hbar \omega \alpha)\), with the Hamiltonian \(H_-\) and the angular momentum \(J_-\) represented by \(A_\alpha\) and \(A_\alpha^\dagger\) defined in (6),

\[
H_- = H_{-a} + H_{-b}, \quad H_{-a} = \hbar \omega_a A_a^\dagger A_a \otimes I_b, \quad H_{-b} = \hbar \omega_b I_a \otimes A_b^\dagger A_b. \tag{19}
\]

\[
J_+ = J_{-a} - J_{-b}, \quad J_{-a} = \hbar \left( A_a^\dagger A_a + \frac{1}{2} \right) \otimes I_b, \quad J_{-b} = \hbar I_a \otimes \left( A_b^\dagger A_b + \frac{1}{2} \right). \tag{20}
\]

where \(I_a\) and \(I_b\) are unit operators in the Hilbert spaces \(\mathcal{H}_a\) and \(\mathcal{H}_b\), respectively, corresponding to modes \(a\) and \(b\). The common eigenstates of \(H_-\) and \(J_-\) are \(|n_a, n_b\rangle = |n_a\rangle|n_b\rangle\) with, respectively, eigenvalues

\[
E_{n_a, n_b}^{(-)} = \hbar \omega_a n_a + \hbar \omega_b n_b,
\]

\[
j_{n_a, n_b}^{(-)} = \hbar (n_a + \frac{1}{2}) - \hbar (n_b + \frac{1}{2})
\]

\((n_a, n_b = 0, 1, 2, \ldots)\) \(\text{(21)}\)
$SU_T$ is defined as

$$\begin{align*}
U &= U_a \otimes U_b, & U^\dagger &= U_a^\dagger \otimes U_b^\dagger, \\
U_a &= (A^\alpha A^\alpha_1)^{-1/2} A^\alpha, & U_a^\dagger &= A^\alpha_1 (A^\alpha A^\alpha_1)^{-1/2} \quad (\alpha = a,b) \quad (22)
\end{align*}$$

with

$$UU^\dagger = I, \quad U^\dagger U = Q,$$  \hspace{1cm} (23)

where

$$Q = Q_a \otimes Q_b, \quad Q_\alpha = A^\alpha_1 (A^\alpha A^\alpha_1)^{-1} A^\alpha \neq I_\alpha \quad (\alpha = a,b) \quad (24)$$

Under $SU_T$ (22), $H_-$ and $J_-$ are transformed into

$$\begin{align*}
H_+ &= U H_- U^\dagger = H_{+a} + H_{+b}, \\
H_{+a} &= \hbar \omega_a A^\dagger_a \otimes I_b, \quad H_{+b} = \hbar \omega_b I_a \otimes A^\dagger_b.
\end{align*}$$

\hspace{1cm} (25)

$$\begin{align*}
J_+ &= U J_- U^\dagger = J_{+a} - J_{+b}, \\
J_{+a} &= \hbar (A^\dagger_a \otimes I_b + \frac{1}{2} I_a \otimes I_b), \quad J_{+b} = \hbar (I_a \otimes A^\dagger_b + \frac{1}{2} I_a \otimes I_b).
\end{align*}$$

\hspace{1cm} (26)

Correspondingly, under $SU_T$ (22) $|n_a,n_b\rangle_-$ is transformed into $U|n_a,n_b\rangle_-$. Notice that $U|0,0\rangle_- = 0$, $U|0,n_b\rangle_- = 0$ and $U|n_a,0\rangle_- = 0$ which shows that the states $|0,0\rangle_-,$ $|0,n_b\rangle_-,$ and $|n_a,0\rangle_-,$ are destroyed by $SU_T$. Thus $|n_a,n_b\rangle_+ = U|n_a + 1,n_b + 1\rangle_- = [E_{n_a+1}^{(-)} E_{n_b+1}^{(-)}]^{-1/2} A_a|n_a + 1\rangle_- \otimes A_b|n_b + 1\rangle_-$ (n.a., n.b. = 0, 1, 2, . . .). The common eigenstates of $H_+$ and $J_+$ are $|n_a,n_b\rangle_+ = U|n_a + 1,n_b + 1\rangle_- \quad$ with, respectively, eigenvalues

$$\begin{align*}
E^{(+)}_{n_a,n_b} &= \hbar \omega_a (n_a + 1) + \hbar \omega_b (n_b + 1), \\
J^{(+)}_{n_a,n_b} &= \hbar (n_a + \frac{3}{2}) - \hbar (n_b + \frac{3}{2}) \quad (n_a,n_b = 0, 1, 2, . . .) \quad (27)
\end{align*}$$

For the (+) system the ground state $|0,0\rangle_+$ has energy $E^{(+)}_{0,0} = \hbar (\omega_a + \omega_b) = 2\hbar \Omega$. Here the states $|0,0\rangle_-,$ $|0,n_b\rangle_-,$ and $|n_a,0\rangle_-$ of $H_-$ with energy $E^{(-)}_{0,0} = 0$, $E^{(-)}_{0,n_b} = \hbar \omega_b n_b$, and $E^{(-)}_{n_a,0} = \hbar \omega_a n_a$ disappear.
Because of the cancellation of the angular momenta between modes $a$ and $b$ the angular momenta $J_-$ and $J_+$ have the same spectrum $j_{n_a,n_b} \equiv \hbar(n_a - n_b) = j_{n_a,n_b}^{(+)} = \text{any integer multiple of } \hbar$. The $(+)$ system still has the same lowest eigenvalue as the $(-)$ system $j_{0,0}^{(+)} = j_{0,0}^{(-)} = 0$.

Now we consider the interesting limit case $M \to 0$ discussed by Baxter [1]. In this case there are constraints which should be carefully considered. The first equation of (2) shows that the limit case $M \to 0$ requires the constraints

$$C_i = P_i + g\epsilon_{ij}R_j/2 = 0. \quad (28)$$

We observe that the Poisson brackets $\{C_i, C_j\} = g\epsilon_{ij} \neq 0$ [8], so that the Dirac brackets can be determined [9]

$$\{R_1, P_1\}_D = \{R_2, P_2\}_D = 1/2, \quad \{R_1, R_2\}_D = -1/g, \quad \{P_1, P_2\}_D = -g/4. \quad (29)$$

Other Dirac brackets of $R_i$ and $P_i$ are zero. The Dirac brackets of $C_i$ with any variables $R_i$ and $P_i$ are zero; thus (28) are strong conditions in the sense of Dirac which can be used to eliminate the dependent variables. Choosing the independent variables $(R_1, P_1)$, (28) fixes the dependent variables $R_2 = -2P_1/g$, $P_2 = gR_1/2$. In the reduced phase space of the independent variables $(R_1, P_1)$ the Hamiltonian (2) has the structure of a one-dimensional harmonic oscillator

$$H = \frac{2K}{g^2} P_1^2 + \frac{1}{2}KR_1^2 \quad (30)$$

According to (29) the quantization condition of the independent variables is $[R_1, P_1] = i\hbar/2$. Set $R_1 = q/\sqrt{2}$, $P_1 = p/\sqrt{2}$ which leads to $[q, p] = i\hbar$. Introduce $V_-(q) = \frac{1}{2}m^*\omega^2q^2 - \frac{1}{2}\hbar\omega$ where the effective mass $m^*$ and the frequency $\omega$ are

$$m^* = \frac{g^2}{2K}, \quad \omega = K/g. \quad (31)$$

Define

$$A = (\hbar/2m^*\omega)^{1/2}d/dq + (m^*\omega/2\hbar)^{1/2}q, \quad A^\dagger = -(\hbar/2m^*\omega)^{1/2}d/dq + (m^*\omega/2\hbar)^{1/2}q, \quad (32)$$
we obtain from (30)

\[ H(\cdot) = \frac{1}{2m^*}[p^2 + (m^* \omega^2 q^2 - m^* \hbar \omega)] = \hbar \omega A^\dagger A \tag{33} \]

with eigenvalues

\[ E_n^(-) = n\hbar \omega \quad (n = 0, 1, 2, \ldots). \tag{34} \]

Observe that if we rewrite (30) as

\[ H = P_1^2/2m_1 + m_1 \omega_1^2 R_1^2/2 \]

where the effective mass

\[ m_1 = g^2/4K \]

and the frequency \( \omega_1 = 2K/g \), we find that the frequency \( \omega \) of (31) differs from that of the conventional harmonic oscillator by a factor of 1/2. This is the representation of the well-known fact that reduction to the reduced phase space alters the symplectic structure \[9\].

In the limit \( M \to 0 \) the angular momentum is

\[ J_\cdot = gR_iR_i/2 = \hbar (A^\dagger A + \frac{1}{2}). \tag{35} \]

The spectrum of \( J_\cdot \) is a positive half-integer multiple of \( \hbar \),

\[ j_n^(-) = \hbar (n + \frac{1}{2}) \quad (n = 0, 1, 2, \ldots). \tag{36} \]

Comparing (33), (35) with (19), (20), we see that in the limit \( M \to 0 \) the mode \( b \) disappears, only the mode \( a \) is maintained \[1\]. Using \( A \) and \( A^\dagger \) defined in (32) we construct \( U = (AA^\dagger)^{-1/2}A \) which is a SUT. With such a SUT, \( H_\cdot \) in (33) and \( J_\cdot \) in (35) are simultaneously transformed into their superpartners

\[
\begin{align*}
H_+ &= U H_- U^\dagger = \hbar \omega AA^\dagger, \\
J_+ &= U J_- U^\dagger = \hbar (AA^\dagger + \frac{1}{2}),
\end{align*} \tag{37}
\]

with, respectively, spectra

\[
\begin{align*}
E_n^+(+) &= \hbar \omega (n + 1), \\
j_n^+(+) &= \hbar (n + 3/2) \quad (n = 0, 1, 2, \ldots). \tag{38}
\end{align*}
\]

Comparing with the spectrum of \( J_- \), the spectrum of \( J_+ \) is also a positive half integer of \( \hbar \), but starting from \( 3\hbar/2 \), the lowest angular momentum \( \hbar/2 \) of \( J_- \) is destroyed by SUT.

A possible experimental verification of the lowest angular momentum of SS cold Rydberg atoms is allowed in principle. In the present case the difference between \( V_+ \) and \( V_- \) is
a constant, \( V_+ - V_- = 2\hbar(g/4M^2 + K/M)^{1/2} \). Taking the limit of vanishing kinetic energy is achieved as follows [1]. If the magnetic field is strong enough, the second term in (2) is dominant. Further, in an appropriate optical trapping field the speed of the atom can be slowed to the extent that the kinetic energy term in (2) may be removed [10], which leads to the limit \( M \to 0 \) [11]. Assuming that the planar, confined dipole is prepared in its energy ground state and interacts with a radiation mode of a Laguerre-Gaussian form (since a Laguerre-Gaussian beam carries orbital angular momentum along its direction of propagation [12]). The expectation value of the angular momentum in the long time limit shows two distinct resonances at \( \omega_a, \omega_b \). As a diminution in the kinetic energy term, the \( b \) resonance occurs at even greater values of frequency, until only the \( a \) resonance remains achievable at \( \omega_a = K/g \). The supersymmetrization of the (−) system can be achieved with a constant shift of the potential \( V_- \). Thus the location and nature of possible angular momentum resonances allow in principle the experimental verification of the lowest angular momentum spectrum of SS cold Rydberg atoms.

To summarize, the main results obtained in this paper are as follows: (1) SUT is applied to discuss supersymmetrization of cold Rydberg atoms. The Hamiltonian and angular momentum of the SS Rydberg atom are simultaneously obtained. This allows the possibility of comparing the relation of angular momenta between the (−) system and (+) system. It is interesting to exploit further possible applications of SUT in physics. (2) In the limit of vanishing kinetic energy the lowest angular momentum of the SS cold Rydberg atom is \( 3\hbar/2 \). The suggested possible experimental verification provides a crucial test of the idea of SS QM.

[7] The semiunitary operator can exist only in infinite dimension space. In finite dimension space, if $UU^\dagger = I$, then $U^\dagger U$ must be a unit operator too. So in finite dimension space there are only unitary operators. It is easy to show that semiunitary operators constitute a semigroup.

[8] Because of the Poisson brackets $\{C_i, C_j\} = g\epsilon_{ij} \neq 0$, the consistency requirement $\dot{C}_i = 0$ fixes the Lagrange multiplier $\lambda_i$ in the first-order Lagrangian with constraints (28). Therefore there is no need to introduce gauge fixing conditions.

[11] The identification of the $M \to 0$ limit with the vanishing kinetic energy limit requires careful analysis. In the $M \to 0$ limit the Lagrangian $L$ in (I) is reduced to $L_0 = \frac{1}{2}g\epsilon_{ij}R_i\dot{R}_j - \frac{1}{2}KR_iR_i$, the corresponding canonical momentum is $P_{0i} = \partial L_0/\partial \dot{R}_i = \frac{1}{2}g\epsilon_{ji}R_j$, and the Hamiltonian is $H_0 = P_{0i}\dot{R}_i - L_0 = \frac{1}{2}KR_iR_i$. On the other hand, the Hamiltonian $H$ in (2) can be rewritten as $H = \frac{1}{2}M\dot{R}_i\dot{R}_i + \frac{1}{2}KR_iR_i$, where the first term $\frac{1}{2}M\dot{R}_i\dot{R}_i$ is the kinetic energy term. Thus the kinetic energy $\to 0$ limit gives $H \to H_0 = \frac{1}{2}KR_iR_i$, which justifies the identification of the two limiting processes. Here the point is that we should clarify the difference between the kinematical momentum and the canonical momentum whenever velocity-dependent forces occur.
