MULTIDIMENSIONAL LAMBERT-EULER INVERSION AND VECTOR-MULTIPLICATIVE COALESCENT PROCESSES

YEVGENIY KOVCHEGOV AND PETER T. OTTO

Abstract. In this paper we show the existence of the minimal solution to the multidimensional Lambert-Euler inversion, a multidimensional generalization of \([-e^{-1}, 0]\) branch of Lambert W function \(W_0(x)\). Specifically, for a given nonnegative irreducible symmetric matrix \(V \in \mathbb{R}^{k \times k}\), we show that for \(u \in (0, \infty)^k\), if equation

\[y_j \exp \{-e_j^TV y\} = u_j \quad \forall j = 1, \ldots, k,\]

has at least one solution, it must have a minimal solution \(y^*\), where the minimum is achieved in all coordinates \(y_j\) simultaneously. Moreover, such \(y^*\) is the unique solution satisfying \(\rho \left(V D[y^*_j]\right) \leq 1\), where \(D[y^*_j] = \text{diag}(y^*_j)\) is the diagonal matrix with entries \(y^*_j\) and \(\rho\) denotes the spectral radius.

Our main application is in the vector-multiplicative coalescent process. It is a coalescent process with \(k\) types of particles and vector-valued weights that begins with \(\alpha_1^n + \ldots + \alpha_k^n\) particles partitioned into types of respective sizes, and in which two clusters of weights \(x\) and \(y\) would merge with rate \((x^TV y)/n\). We use combinatorics to solve the corresponding modified Smoluchowski equations, obtained as a hydrodynamic limit of vector-multiplicative coalescent as \(n \to \infty\), and use multidimensional Lambert-Euler inversion to establish gelation and find a closed form expression for the gelation time.

We also find the asymptotic length of the minimal spanning tree for a broad range of graphs equipped with random edge lengths.

1. Introduction

In his 1783 work \[9\] L. Euler considered the following transcendental equation entailed from 1758 work of J. H. Lambert \[21\]

\[x^\alpha - x^\beta = (\alpha - \beta)v x^{\alpha+\beta}.\]

Letting \(\alpha \to \beta\) in (1), Euler obtained

\[\ln x = v x^\beta.\]

Next, Euler set \(y = x^\beta\) and \(u = \alpha v\) in (2), obtaining

\[\frac{\ln y}{y} = u.\]

Letting \(y = e^w\), equation (3) yields

\[we^{-w} = u.\]

Equation (4) gave rise to the Lambert W function, and in particular the function \(W_0(x)\) for \(-e^{-1} \leq x < 0\).
Denote \( R_0 = (0, 1) \), \( \overline{R}_0 = (0, 1] \), and \( R_1 = (1, \infty) \). Then, for each \( 0 < u < e^{-1} \) there are exactly two solutions \( w \) of (4). Moreover, one solution is always in \( R_0 \) and one solution is always in \( R_1 \). For \( u = e^{-1} \), \( w = 1 \) is the only solution. Thus, for \( 0 < u \leq e^{-1} \), there exists exactly one solution \( w \) of (4) in \( \overline{R}_0 \). This solution is either unique when \( u = 1 \) or is the smaller of the two solutions when \( 0 < u < e^{-1} \).

Let \( e \) denote the column vector representation of vector \( x \). With coordinates \( x_i \), \( D[x_i] \) denotes the diagonal matrix with entries \( x_i \), and \( \rho(M) \) denotes the spectral radius of matrix \( M \).

In this paper we will study the multidimensional Lambert-Euler inversion problem. Let \( V \in \mathbb{R}^{k \times k} \) be a nonnegative irreducible symmetric matrix. For a given vector \( z \in (0, \infty)^k \), consider region

\[
R_0 = \left\{ z \in (0, \infty)^k : \rho(VD[z]) < 1 \right\}
\]

its closure within \((0, \infty)^k\),

\[
\overline{R}_0 = \left\{ z \in (0, \infty)^k : \rho(VD[z]) \leq 1 \right\},
\]

and the complement of \( \overline{R}_0 \) within \((0, \infty)^k\),

\[
R_1 = \left\{ z \in (0, \infty)^k : \rho(VD[z]) > 1 \right\},
\]

where for a vector \( x \in \mathbb{R}^k \) with coordinates \( x_i \), \( D[x_i] \) denotes the diagonal matrix with entries \( x_i \), and \( \rho(M) \) denotes the spectral radius of matrix \( M \).

In this paper we found it convenient to use bra-ket notation of P. Dirac. Specifically, \(|x|\) will denote the column vector representation of vector \( x \in \mathbb{R}^k \), and \((x)\) will denote the row vector representation of vector \( x \in \mathbb{R}^k \). For \( c \in \mathbb{R} \) and \( x \in \mathbb{R}^k \), \( cx \) will represent the product \( cx \), a column vector. Respectively, \(|x|y) = (y|x)\) will be the dot product of \( x \) and \( y \) in \( \mathbb{R}^k \). Finally, for a matrix \( M \in \mathbb{R}^{k \times k} \), \((x|M|y)\) will represent the product \( x^TMy \) resulting in a scalar.

Let \( e_j \) denote the \( j \)-th standard basis vector. The following theorem is the main result of the paper.

**Theorem 1.1** (Multidimensional Lambert-Euler inversion). Consider a nonnegative irreducible symmetric matrix \( V \in \mathbb{R}^{k \times k} \). For any given \( z \in (0, \infty)^k \), there exists a unique vector \( y \in \overline{R}_0 \) such that

\[
y_j e^{-\langle e_j | V | y \rangle} = z_j e^{-\langle e_j | V | z \rangle} \quad j = 1, \ldots, k.
\]

Moreover, if \( z \in \overline{R}_0 \), then \( y = z \). If \( z \in R_1 \), then \( y < z \) (\( y_i < z_i \ \forall i \)), i.e., \( y \) is the smallest solution of (9).
Theorem 1.1 which we will prove in Section 2, yields the following multidimensional analogue of \([-e^{-t}, 0]\) branch of Lambert W function \(W_0(x)\). Consider domain

\[
\mathcal{D} = \left\{ u \in (0, \infty)^k : \exists z \in (0, \infty)^k \text{ such that } |u| = \sum_{j=1}^{k} z_j e^{-\langle e_j | V | z \rangle} e_j \right\}.
\]

Then, by Theorem 1.1

\[
\mathcal{D} = \left\{ u \in (0, \infty)^k : \exists z \in \overline{R}_0 \text{ such that } |u| = \sum_{j=1}^{k} z_j e^{-\langle e_j | V | z \rangle} e_j \right\}
\]

and for the mapping \(\Psi_V : (0, \infty)^k \to \mathcal{D}\) defined as \(|\Psi_V(z)| = \sum_{j=1}^{k} z_j e^{-\langle e_j | V | z \rangle} e_j\), Theorem 1.1 implies that restricting the domain of \(\Psi_V\) to \(\overline{R}_0\), makes \(\Psi_V\) a continuous bijection from \(\overline{R}_0\) to \(\mathcal{D}\). Thus, we can define Lambert-Euler inversion \(\Lambda_V\) of \(\Psi_V\) as a continuous bijection from \(\mathcal{D}\) to \(\overline{R}_0\). Thus, for any given \(z \in (0, \infty)^k\), equation (9) has the minimal solution \(y = \Lambda_V \circ \Psi_V(z) \in \overline{R}_0\), where the minimum is achieved in all coordinates.

Now, we can define a multidimensional analogue of function \(x(t)\) in (5). For any given \(\alpha \in (0, \infty)^k\), let \(y(t) = \Lambda_V \circ \Psi_V(\alpha t)\) for all \(t > 0\), i.e., \(y(t)\) is the minimal solution of

\[
y_j e^{-\langle e_j | V | y \rangle} = \alpha_j t e^{-t \langle e_j | V | \alpha \rangle} \quad \forall j = 1, \ldots, k.
\]

Consequently, \(y(t) = \Lambda_V \circ \Psi_V(\alpha t)\) is a continuous function.

By analogy with \(\lim_{t \to \infty} \frac{x(t)}{t} = 0\) for \(x(t)\) in (5), we will show that \(\lim_{t \to \infty} \frac{y(t)}{t} = 0\). This will be done in Lemma 2.7 of Section 2.

Next, we will list the applications of Theorem 1.1.

1.1. Vector-Multiplicative Coalescent Processes. The solution to the multidimensional Lambert-Euler inversion given in Theorem 1.1 and the function \(y(t)\) defined in (12) will be used in the analysis of a general class of coalescent processes introduced here that we will call the vector-multiplicative coalescent processes.

For a nonnegative irreducible symmetric matrix \(V \in \mathbb{R}^{k \times k}\) and a given vector \(\alpha \in (0, \infty)^k\), let

\[
\alpha[n] = \begin{bmatrix} \alpha_1[n] \\ \vdots \\ \alpha_k[n] \end{bmatrix} = \alpha n + o(\sqrt{n}).
\]

Consider a system with \(k\) types of particles, 1, \ldots, \(k\), and the coalescent process that begins with \(\langle \alpha[n] | 1 \rangle = \langle \alpha[1]n + o(\sqrt{n}) \rangle\) singletons distributed between the \(k\) types so that for each \(i\), there are \(\alpha_i[n] = \alpha_i n + o(\sqrt{n})\) particles of type \(i\). In this continuous time Markov process, a particle of type \(i\) bonds with a particle of type \(j\) with the rate \(v_{i,j}/n\), where \(v_{i,j} = \langle e_i | V | e_j \rangle\) is the \((i,j)\) element in the matrix \(V\). The bonds are formed independently. This process is called vector-multiplicative coalescent.

Formally, vector-multiplicative coalescent process describes cluster merger dynamics, where the weight of each cluster is a \(k\)-dimensional vector \(x \in \mathbb{Z}_+^k\) such that \(\langle x | 1 \rangle > 0\). Each cluster of
weight \( x \) bonds together \( x_1, \ldots, x_k \) particles of corresponding types 1, \ldots, \( k \). The coalescent process begins with \( (\alpha[n])_1 \) singletons of all \( k \) types, of which there are \( \alpha_i[n] \) of type \( i \) (for all \( i = 1, \ldots, k \)). Each pair of clusters with respective weight vectors \( x \) and \( y \) would coalesce into a cluster of weight \( x + y \) with rate \( K(x, y) / n \), where

\[
K(x, y) = \langle x | V | y \rangle.
\]

The last merger will create a cluster of weight \( \alpha[n] \).

The kernel \( K(x, y) \) defined in (14) will be referred to as the \textit{vector-multiplicative kernel}. The kernel is symmetric

\[
K(x, y) = K(y, x)
\]

and bilinear

\[
K(c_1 x + c_2 y, z) = c_1 K(x, z) + c_2 K(y, z)
\]

for all vectors \( x, y, z \) and scalars \( c_1, c_2 \).

Notice that coalescent processes with vector-valued weights have been considered in the past. See [18, 19, 30].

In the vector-multiplicative coalescent process, let \( \zeta_x[n](t) \) denote the number of clusters of weight \( x \) at time \( t \geq 0 \). The initial values are \( \zeta_x[n](0) = \sum_{i=1}^k \alpha_i[n] \delta_{e_i, x} \). The process

\[
\text{ML}_n(t) = \left( \zeta_x[n](t) \right)_{x \in \mathbb{Z}_1^k : \langle x | 1 \rangle > 0}
\]

that counts clusters of all types in the vector-multiplicative coalescent process is the corresponding Marcus-Lushnikov process. In Lemma 3.1 we will refer to the known weak limit result of T. G. Kurtz for \textit{density dependent population processes} that yields convergence of \( \zeta_x[n](t) \) to \( \zeta_x(t) \), where \( \zeta_x(t) \) is the solution to the \textit{modified Smoluchowski equations} (MSE)

\[
\frac{d}{dt} \zeta_x(t) = -\zeta_x(x | V | \alpha) + \frac{1}{2} \sum_{y, z : y + z = x} \langle y | V | z \rangle \zeta_y \zeta_z
\]

with the same initial conditions \( \zeta_x(0) = \sum_{i=1}^k \alpha_i \delta_{e_i, x} \).

In Section 3.3 we will find the unique solution \( \zeta_x(t) \) of the above modified Smoluchowski equations. Specifically, for a vector \( x \in \mathbb{Z}_1^k \) let \( x! = x_1! x_2! \ldots x_k! \) and for vectors \( a \) and \( b \) in \( \mathbb{R}^k \) let \( a^b = a_1^b_1 a_2^b_2 \ldots a_k^b_k \) whenever \( a_i^b_i \) is uniquely defined for all \( i \). Now, consider a complete graph \( K_k \) consisting of vertices \( \{1, \ldots, k\} \) with weights \( w_{i,j} = w_{j,i} \geq 0 \) assigned to its edges \( [i, j] \) \( (i \neq j) \). Let the weight \( W(T) \) of a spanning tree \( T \) be the product of the weights of all of its edges. Finally, let \( \tau(K_k, w_{i,j}) = \sum_T W(T) \) denote the \textit{weighted spanning tree enumerator}, i.e., the sum of weights of all spanning trees in \( K_k \). These notations are used in the following closed form expression, that will be established in Corollary 3.11 of Section 3.3

\[
\zeta_x(t) = \frac{1}{x!} \alpha^x \tau(K_k, x_i x_j v_{i,j}) (V x)^{x-1} e^{-\langle x | V | \alpha \rangle t} |x(1)|^{-1}.
\]

The concept of \textit{gelation} was studied in [2, 3, 13, 14, 26, 28, 29, 31] and related papers. For the hydrodynamic limit \( \zeta_x(t) \) of the Marcus-Lushnikov process with vector-multiplicative kernel,
the gelation time $T_{gel}$ is the time after which the total mass $\sum_x \zeta(x)|x|$ begins to dissipate, i.e., while the initial total mass was $\sum_x \zeta(x)|x| = |\alpha|$, 

$$T_{gel} = \inf \left\{ t > 0 : \sum_x \zeta(x)|x| < |\alpha| \right\}.$$ 

In Section 4.1 we will use Corollary 2.6 of the Multidimensional Lambert-Euler inversion Theorem [12] for establishing gelation in the coagulation process with the vector-multiplicative kernel [14] and find the value of the gelation time. Specifically, we will show that the gelation time equals to 

$$T_{gel} = \frac{1}{\rho(VD[\alpha])}.$$ 

1.2. Application in minimal spanning trees. Another application concerns the problem of finding the asymptotic mean length of the minimal spanning tree in a graph equipped with independent random edge lengths as studied in [4, 6, 10, 12] and related research works. Let $K_{\alpha[n]}$ denote a graph with $\langle \alpha[n]|1 \rangle = \langle \alpha|1 \rangle + o(\sqrt{n})$ vertices divided into $k$ partitions of respective sizes 

$$\alpha_1[n], \ldots, \alpha_k[n],$$ 

where, each vertex in the $i$-th partition is connected with each vertex in the $j$-th partition by an edge if and only if $v_{i,j} = v_{j,i} > 0$. Even within an $i$-th partition, if $v_{i,i} > 0$, a pair of vertices is connected by an edge.

Now, we equip the edges in the graph $K_{\alpha[n]}$ with edge lengths as follows. For each edge $e$ connecting a vertex in the $i$-th partition with a vertex in the $j$-th partition we have an associated random variable $\ell_e \sim \text{Beta}(1, v_{i,j})$, distributed on $(0, 1)$ via the beta probability density function 

$$f_{i,j}(x) = v_{i,j}(1 - x)^{v_{i,j} - 1}, \quad 0 < x < 1.$$ 

Random variables $\{\ell_e\}$ are sampled independently. Here, $\ell_e$ represents the length of edge $e$.

The length of a tree graph is the sum of the lengths $\ell_e$ of its edges. Consider the minimal spanning tree of $K_{\alpha[n]}$, i.e., a spanning tree of $K_{\alpha[n]}$ with the minimal length. Let random variable $L_n$ denote the length of the minimal spanning tree of $K_{\alpha[n]}$. We are interested in finding the limit $\lim_{n \to \infty} \mathbb{E}[L_n]$. Following the approach in [15], $\lim_{n \to \infty} \mathbb{E}[L_n]$ will be expressed using the closed form solution [15] of the modified Smoluchowski equations.

The connection between the limit $\lim_{n \to \infty} \mathbb{E}[L_n]$ and $\zeta_x(t)$ is established using the following framework. First, we construct a random graph process by considering a “time” parameter $p \in [0, 1]$, and declaring an edge $e$ “open” if $\ell_e \leq p$ and “closed” if $\ell_e > p$. Thus, at time $p$, we have a graph consisting of $\langle \alpha[n]|1 \rangle$ vertices and all open edges. The random graph process $G(n, p)$ describes the corresponding percolation dynamics on graph $K_{\alpha[n]}$ equipped with edge lengths $\ell_e$. Process $G(n, p)$ partitions $K_{\alpha[n]}$ into clusters of vertices connected by open edges at time $p$.

Notice that under the time change $p = 1 - e^{-t/n}$ with $t \in [0, \infty)$, for an edge $e$ connecting a vertex in the $i$-th partition with a vertex in the $j$-th partition we have 

$$P(\ell_e \leq 1 - e^{-t/n}) = 1 - e^{-tv_{i,j}/n}.$$
Thus, in $G(n, 1 - e^{-t/n})$, an edge adjacent to a vertex in the $i$-th partition and a vertex in the $j$-th partition would open after waiting for an exponentially distributed arrival time with parameter $v_{i,j}/n$.

There is a one-to-one correspondence between connected clusters in $G(n, p)$ and vectors in $\mathbb{Z}^k_+$. Namely, a cluster with $x_i$ vertices in the $i$-th partition is represented by a vector $x$ in $\mathbb{Z}^k_+$ with coordinates $x_i$. Consider the random graph process $G(n, 1 - e^{-t/n})$. For two clusters composed of two disjoint subsets of vertices in $K\alpha[n]$, represented by vectors $x$ and $y$, the waiting time for the clusters to connect via an open edge will be an exponential random variable with parameter $\langle x|V|y \rangle/n$. Hence, the merger dynamics of clusters in the random graph process $G(n, 1 - e^{-t/n})$ matches the merger dynamics of clusters in the vector-multiplicative coalescent process. That is, if we let $\xi^n_x(t)$ denote the number of clusters represented by vector $x$ in $G(n, 1 - e^{-t/n})$, then $\xi^n_x(t)$ is distributed as the Marcus-Lushnikov process $ML_n(t) = \left(\xi^n_x(t)\right)_x$.

As $\xi^n_x(t)$, and therefore, $\xi^n_x(t)$ converges weakly to $\zeta_x(t)$, the approach in [18] yields

$$\lim_{n \to \infty} E[L_n] = \sum_{x \, : \, \langle x | 1 \rangle > 0} \int_0^\infty \zeta_x(t) \, dt.$$ 

In Corollary 5.2 the closed form expression (15) of the solution $\zeta_x(t)$ to the modified Smoluchowski equations is substituted, yielding the following general asymptotic equation

$$\lim_{n \to \infty} E[L_n] = \sum_{x \, : \, \langle x | 1 \rangle > 0} \frac{(\langle x | 1 \rangle - 1)!}{x!} \frac{\alpha^\tau(K_k, x_i x_j v_{i,j})}{x!} (Vx)^{x-1} \langle x | V | x \rangle^{\langle x | 1 \rangle}.$$ 

Additionally, recalling a known correspondence between the gelation time $T_{gel}$ in the Marcus-Lushnikov process and the time $p_c$ of formation of a giant component in $G(n, p)$, we have $p_c \sim 1 - e^{-T_{gel}/n} \sim T_{gel}/n$. Hence,

$$p_c \sim \frac{1}{n \rho(VD[\alpha_i])}.$$ 

Finally, random graph processes $G(n, 1 - e^{-t/n})$ have many features similar to the inhomogeneous random graphs formalism considered in Söderberg [27], Bollobás et al [5], and related papers. We hope that the results of this current manuscript can be used in the study of inhomogeneous random graphs.

We conclude the introduction by noticing that the parts of the paper on Smoluchowski coagulation equations and on spanning trees are tied to a number of interesting Abel’s type multinomial identities such as [61].
2. MULTIDIMENSIONAL LAMBERT-EULER INVERSION

In this section we will prove Theorem 1.1 that enables the multidimensional Lambert-Euler inversion. Additionally, in Lemma 2.7 we will show that for $\alpha \in (0, \infty)^k$, $\lim_{t \to \infty} \frac{y(t)}{t} = 0$.

For $z \in (0, \infty)^k$, let function $F(x; z)$ be defined as follows

$$|F(x; z)| = |x| - \sum_{j=1}^k z_j e^{(e_j|V|x-z)|e_j|}, \quad \forall x \in (0, \infty)^k.$$ 

Notice that a root $x$ of $F(x; z)$ is a solution of (9). Next, for a given $z \in (0, \infty)^k$, we find the Jacobian matrix of $F(x; z)$ in the equation below

$$\frac{\partial F(x; z)}{\partial x} = I - \sum_{i,j=1}^k z_j e^{(e_j|V|x-z)|e_j|} e_j^i V_i = I - \sum_{j=1}^k z_j e^{(e_j|V|x-z)|e_j|} e_j^i V_i$$

$$= I - D \left[ z_j e^{(e_j|V|x-z)|e_j|} \right] V. \tag{16}$$

We will need the following trivial proposition.

**Proposition 2.1.** For a given pair of vectors $a \neq b$ in $(0, \infty)^k$, if $a_i \leq b_i$ for all coordinates $i$, then $\rho(VD[a_j]) < \rho(VD[b_j])$.

The following lemma is instrumental for establishing uniqueness in Theorem 1.1.

**Lemma 2.2.** If $y, z \in \mathbb{R}_0$ satisfy equation (9), then $y = z$.

**Proof.** We will prove this statement by contradiction. Suppose there is a pair $y, z \in \mathbb{R}_0$ satisfying $y \neq z$ and (9). Then, $F(y; z) = 0$. Consider a set of indices $I = \{i : y_i < z_i\}$, and let $I^c = \{i : y_i \geq z_i\}$ denote its complement.

Next, consider a point $x^*$ with coordinates

$$|x^*| = |z| + \sum_{i \in I} (y_i - z_i)|e_i|$$

and a path $x(t), \ t \in [0, 1]$, connecting $z$ and $y$ defined as

$$|x(t)| = \begin{cases} |z| + 2t|x^* - z| & \text{for } t \in [0, 1/2], \\ |x^*| + (2t - 1)|y - x^*| & \text{for } t \in [1/2, 1]. \end{cases} \tag{17}$$
Now, since \( F(y; z) = F(z; z) = 0 \), then from (16) and (17) we have

\[
0 = F(y; z) - F(z; z) = \int_0^1 |dF(x(t); z)| = \int_0^1 \frac{\partial F(x; z)}{\partial x} \left| d\mathbf{x}(t) \right|
\]

\[
= \int_0^{1/2} \frac{\partial F(x; z)}{\partial x} \left| d\mathbf{x}(t) \right| + \int_{1/2}^1 \frac{\partial F(x; y)}{\partial x} \left| d\mathbf{x}(t) \right|
\]

\[
= 2 \int_0^{1/2} \left( I - D \left[ z_j e^{2t(\epsilon_j|V|\mathbf{x}^* - \mathbf{z})} V \right] \mathbf{x}^* - \mathbf{z} \right) dt + 2 \int_{1/2}^1 \left( I - D \left[ y_j e^{2(t-1)(\epsilon_j|V|\mathbf{y} - \mathbf{x}^*)} V \right] \mathbf{y} - \mathbf{x}^* \right) dt
\]

(18) \hspace{1cm} |y - z| - |\mathcal{E}_I| - |\mathcal{E}_{II}|

where

\[
|\mathcal{E}_I| = 2 \int_0^{1/2} D \left[ z_j e^{2t(\epsilon_j|V|\mathbf{x}^* - \mathbf{z})} V \right] \mathbf{x}^* - \mathbf{z} \right) dt = D[z_j a_j V]|\mathbf{x}^* - \mathbf{z}|
\]

with

\[
a_j = \begin{cases} 
\frac{1 - e^{-(\epsilon_j|V|\mathbf{a} - \mathbf{z})}}{\epsilon_j |V| \mathbf{x}^* - \mathbf{z}} & \text{if } j \in \mathcal{I}, \\
1 & \text{if } j \in \mathcal{I}^c,
\end{cases}
\]

and similarly,

\[
|\mathcal{E}_{II}| = 2 \int_{1/2}^1 D \left[ y_j e^{2(t-1)(\epsilon_j|V|\mathbf{y} - \mathbf{x}^*)} V \right] \mathbf{y} - \mathbf{x}^* \right) dt = D[y_j b_j V]|\mathbf{y} - \mathbf{x}^*|
\]

with

\[
b_j = \begin{cases} 
\frac{1 - e^{-(\epsilon_j|V|\mathbf{b} - \mathbf{z})}}{\epsilon_j |V| \mathbf{y} - \mathbf{x}^*} & \text{if } j \in \mathcal{I}, \\
1 & \text{if } j \in \mathcal{I}^c.
\end{cases}
\]

Notice that for \( j \in \mathcal{I} \), we have \( \langle \epsilon_j |V| \mathbf{z} - \mathbf{x}^* \rangle > 0 \) and \( a_j = \frac{1 - e^{-(\epsilon_j|V|\mathbf{a} - \mathbf{z})}}{\epsilon_j |V| \mathbf{x}^* - \mathbf{z}} \in (0, 1) \). Similarly, for \( j \in \mathcal{I}^c \), we have \( \langle \epsilon_j |V| \mathbf{y} - \mathbf{x}^* \rangle > 0 \) and \( b_j = \frac{1 - e^{-(\epsilon_j|V|\mathbf{y} - \mathbf{x}^*)}}{\epsilon_j |V| \mathbf{y} - \mathbf{x}^*} \in (0, 1) \). Thus, by Proposition 2.1

(21) \hspace{1cm} \rho(D[z_j a_j V] \leq \rho(D[z_j] V) \quad \text{and} \quad \rho(D[y_j b_j V] \leq \rho(D[y_j] V),
\]

where the first inequality is strict if \( \mathbf{z} \neq \mathbf{x}^* \) and the second inequality is strict if \( \mathbf{y} \neq \mathbf{x}^* \).

Now, since \( |\mathcal{E}_I| \) in (19) has all nonpositive coordinates and \( |\mathcal{E}_{II}| \) in (20) has all nonnegative coordinates, we have

\[
\langle \mathcal{E}_I | \mathcal{E}_{II} \rangle = \langle \mathcal{E}_{II} | \mathcal{E}_I \rangle \leq 0.
\]
Therefore, since \( \rho(D[y_j]V) \leq 1 \) and either \( y \neq x^* \) or \( z \neq x^* \) or both hold, equations (19), (20), and (21) imply
\[
\|E_1 + E_{II}\|^2 \leq \|E_1\|^2 + \|E_{II}\|^2 < \rho^2(D[z_j]V) \|z - x^*\|^2 + \rho^2(D[y_j]V) \|y - x^*\|^2
\]
\[
\leq \|z - x^*\|^2 + \|y - x^*\|^2 = \|y - z\|^2
\]
as \( \langle y - x^* | z - x^* \rangle = 0 \). The contradiction to equation (18) follows. \( \square \)

Let \( |1\rangle = \sum_{i=1}^{k} |e_i\rangle \) denote the vector with all of its coordinates equal to 1, and let \( |0\rangle \) denote the vector of zeros. For a vector \( x \in (0, \infty)^k \) with coordinates \( x_i \), let \( |x^{-1}\rangle = \sum_{i=1}^{k} x_i^{-1} |e_i\rangle \) denote the vector with coordinates \( x_i^{-1} \). Also, for vectors \( a \) and \( b \) in \( \mathbb{R}^k \), we will write \( a < b \) if \( a_i < b_i \) for all \( i \). Similarly, for matrices \( A \) and \( B \) in \( \mathbb{R}^{k \times k} \), we will write \( A < B \) if the inequality holds coordinate-wise.

We will need the following lemma.

**Lemma 2.3.** For any given \( z \in R_1 \), there exists a vector \( \eta = \sum_{i=1}^{k} \eta_i |e_i\rangle \) such that
\[
0 < \eta_i < 1 \quad \forall i,
\]
\[
\rho(VD[z_j]D) = 1, \quad \text{and}
\]
\[
VD[z_j]|1 - \eta\rangle = |\eta^{-1}\rangle - |1\rangle.
\]

**Proof.** Let \( u > 0 \) (i.e., \( u_i > 0 \) \( \forall i \)) be the Perron-Frobenius eigenvector of \( VD[z_j] \), then since \( \rho(VD[z_j]) > 1 \), we have
\[
\langle e_i | VD[z_j] - I | u \rangle > 0 \quad \text{for all } i,
\]
and therefore
\[
\langle e_i | VD[z_j] | u \rangle > u_i \quad \text{for all } i.
\]

Consider two sequences of vectors in \((0, \infty)^k\), \( \eta^{(k)} \) and \( w^{(k)} \) evolving according to the following recursion
\[
\eta^{(k)}_i = \frac{1}{1 + \langle e_i | VD[z_j] | w^{(k-1)} \rangle} \quad \text{and} \quad w^{(k)} = 1 - \eta^{(k)}.
\]

Let the sequences begin with \( w^{(0)} = 1 - \eta^{(0)} = \varepsilon u \) with \( \varepsilon > 0 \) sufficiently small so that \( w^{(0)} < 1 \), and by (23),
\[
\eta^{(1)}_i = \frac{1}{1 + \langle e_i | VD[z_j] | w^{(0)} \rangle} = 1 - \langle e_i | VD[z_j] | w^{(0)} \rangle + O(\varepsilon^2) < 1 - w^{(0)}_i = \eta^{(0)}_i \quad \text{for all } i.
\]

Then, \( \eta^{(0)} > \eta^{(1)} \), and by (24), \( w^{(1)} > w^{(0)} \), which in turn implies \( \eta^{(1)} > \eta^{(2)} \), and so on. Recursively obtaining
\[
\eta^{(k)} > \eta^{(k+1)} \quad \text{and} \quad w^{(k+1)} > w^{(k)}
\]
for all \( k = 0, 1, \ldots \). Hence, the limits
\[
\lim_{k \to \infty} \eta^{(k)} = \eta \quad \text{and} \quad \lim_{k \to \infty} w^{(k)} = w.
\]
satisfy
\[ 0 < \eta_j = 1 - w \leq 1 \quad \text{and} \quad \eta_i = \frac{1}{1 + (e_i |VD[z_j]| w)} \quad \text{for all } i. \]

Equation (25) implies
\[ \eta_i (e_i |VD[z_j]| w) = 1 - \eta_i = w_i \quad \text{for all } i. \]

Thus, \( \eta_i w_i^{-1} = (e_i |VD[z_j]| w)^{-1} = (e_i |VD[z_j w_j]| 1)^{-1} \), and
\[ D[\eta_j w_j^{-1}] |VD[z_j w_j]| 1) = |1), \]

i.e., all the rows of \( D[\eta_j w_j^{-1}] |VD[z_j w_j]| \) add up to 1.

For the vector \( |w \eta^{-1} = \sum_{i=1}^k w_i \eta_i^{-1} |e_i) \), equation (26) yields
\[ VD[z_j \eta_j]|w \eta^{-1) = D[w_j \eta_j^{-1}] D[\eta_j w_j^{-1}] |VD[z_j w_j]| 1) = D[w_j \eta_j^{-1}] |1) = |w \eta^{-1}. \]

Hence, by Perron-Frobenius theorem, 1 is the Perron-Frobenius eigenvalue of \( VD[z_j \eta_j] \), the spectral radius \( \rho(VD[z_j \eta_j]) = 1 \), and \( |w \eta^{-1} \) is the corresponding Perron-Frobenius eigenvector.

Therefore, as \( 1 - \eta = w \),
\[ VD[z_j]|1 - \eta = VD[z_j \eta_j]|w \eta^{-1) = |w \eta^{-1} = |\eta^{-1} - |1) \]

yielding the claim in (22). \( \square \)

**Lemma 2.4.** For any given \( z \in R_1 \), there exists a unique vector \( y \in R_0 \) such that (9) is satisfied. Moreover, \( y < z \).

**Proof.** For \( x \in (0, \infty)^k \) with coordinates \( x_i \), let \( |\ln x) = \sum_{i=1}^k \ln x_i |e_i) \) denote the vector with coordinates \( \ln x_i \). Consider function \( f_z : (0, \infty)^k \rightarrow \mathbb{R}^k \) defined as follows:
\[ (27) \quad |f_z(\xi) = |\ln \xi) + VD[z_j]|1 - \xi), \quad \xi \in (0, \infty)^k. \]

For the vector \( \eta \) in Lemma 2.4 we have
\[ |f_z(\eta) = |\ln \eta) + VD[z_i]|1 - \eta) = -|\ln \eta^{-1} + |\eta^{-1} - |1) = -\sum_{i=1}^k \ln \left( \eta_i^{-1} e^{1-\eta_i^{-1}} \right) |e_i > 0 \]

since \( \eta_i^{-1} > 1 \quad \forall i \) and \( xe^{1-x} < 1 \) for all positive \( x \neq 1 \).

Now, since \( |f_z(\eta) > 0 \), by continuity of \( f_z(\xi), \) there exists \( \delta \in (0, 1) \) sufficiently small so that \( \tilde{\eta} = (1 - \delta) \eta \) satisfies
\[ |f_z(\tilde{\eta}) > 0. \]

Notice that since \( \rho(VD[z_j \eta_j]) = 1 \), we have \( \rho(VD[z_j \eta_j]) = 1 - \delta < 1 \).

Next, consider a smooth curve \( x(t) \) in \( (0, \infty)^k \) that begins at \( x(0) = \tilde{\eta} \) and evolves according to the following differential equations:
\[ (28) \quad \frac{d}{dt} x_i(t) = -x_i(t) \sum_{m=0}^\infty (e_i |VD[z_j x_j(t)]|^m |f_z(\tilde{\eta})) \quad i = 1, \ldots, k. \]
As each $x_i(t)$ is monotone decreasing to 0 at exponentially fast rate as $t \to \infty$, and since $\rho(VD[z_j x_j(0)]) < 1$, by Prop. 2.1 we have $\rho(VD[z_j x_j(t)]) < 1$ for all $t \geq 0$. Thus,

$$\sum_{m=0}^{\infty} (VD[z_j x_j(t)])^m = (I - VD[z_j x_j(t)])^{-1}$$

is well-defined for all $t \geq 0$. Therefore, (28) yields

$$\frac{d}{dt} \ln x(t) = -(I - VD[z_j x_j(t)])^{-1} |f_z(\tilde{\eta})|$$

and

$$|f_z(x(t))| = |f_z(\tilde{\eta})| + \ln x(t) - \ln \tilde{\eta} + VD[z_i] |\tilde{\eta} - x(t)|$$

$$= |f_z(\tilde{\eta})| + \int_{0}^{t} \left( D[1/x_j(s)] - VD[z_i] \right) |dx(s)|$$

$$= |f_z(\tilde{\eta})| + \int_{0}^{t} (I - VD[z_j x_j(s)]) |d\ln x(s)|$$

$$= |f_z(\tilde{\eta})| - \int_{0}^{t} |f_z(\tilde{\eta})| ds = (1 - t) |f_z(\tilde{\eta})|.$$ 

Hence, substituting $t = 1$ into (29) yields

$$|f_z(x(1))| = 0,$$

where $x(1) < x(0) = \tilde{\eta} < \eta < 1$. Next, we let $y = D[z_j] x(1) = \sum_{i=1}^{k} z_i x_i(1) e_i$, then by Prop. 2.1

$$\rho(VD[y_j]) = \rho(VD[z_j x_j(1)]) < \rho(VD[z_j \tilde{\eta}_j]) < 1,$$

i.e., $y \in R_0$. Also, $x(1) < 1$ yields

$$y < z.$$ 

Finally, equations (30) and $x_i(1) = y_i z_i^{-1}$ imply

$$0 = |f_z(x(1))| = |\ln x(1) + VD[z_i] 1 - x(1)| = |\ln y| - |\ln z| + V|z - y|$$

arriving at

$$|\ln y| - V|y| = |\ln z| - V|z|,$$

equivalent to equation (39). □

Lemmas 2.2 and 2.4 yield the following simple corollary.

**Corollary 2.5.** If $\rho(VD[z_j]) = 1$, then $y = z$ is the only solution of (39).

Now, we have a proof of the Multidimensional Lambert-Euler inversion.
Proof of Theorem 1.1. The statement in Theorem 1.1 follows immediately from Lemmas 2.2 and 2.4 and Corollary 2.5.

Theorem 1.1 yields the following corollary.

Corollary 2.6. Let $y(t) = \Lambda_V \circ \Psi_V(\alpha t)$ be the minimal solution of (12). Then,

(a) $y(t) = \alpha t$ for all $t \leq \frac{1}{\rho(VD[\alpha_j])}$;
(b) $y(t) < \alpha t$ for all $t > \frac{1}{\rho(VD[\alpha_j])}$.

Notice that $\lim_{t \to \infty} \frac{x(t)}{t} = 0$ for $x(t)$ in (5) which, in the context of random graphs, is analogous to the absorption of connected components of various sizes by a giant component in Erdős-Rényi random graph model [7]. We have the corresponding multidimensional result.

Lemma 2.7. For any given $\alpha \in (0, \infty)^k$, let $y(t) = \Lambda_V \circ \Psi_V(\alpha t)$ be the minimal solution of (12). Then,

$$\lim_{t \to \infty} y(t) = 0.$$

Proof. Let $v_{i,j} = \langle e_i|V|e_j \rangle$ denote the entries in matrix $V$. Recall that $V$ is nonnegative irreducible symmetric matrix. Thus, $v_{i,j} = v_{j,i} \geq 0$ for all $i, j$.

Recall that $y_i(t) \leq \alpha_i t$ for all $i$ and all $t > 0$. Equation (12) implies

$$\frac{y_i(t)}{t} = \alpha_i e^{-t\langle e_i|V|\alpha - y/t \rangle} \quad \text{for all} \quad i = 1, \ldots, k,$$

where $y = y(t)$. First, we claim that

$$\limsup_{t \to \infty} \frac{1}{t} \langle 1|y \rangle < \langle 1|\alpha \rangle.$$

We prove (32) by contradiction as follows. Suppose, not. Then, there exists a sequence $t_m > 0$ increasing to $\infty$, such that

$$\lim_{m \to \infty} \frac{1}{t_m} \langle 1|y(t_m) \rangle = \langle 1|\alpha \rangle.$$

Hence, for all $m$ sufficiently large, $y_i(t_m) > \alpha_i t_m/2$ for all $i = 1, \ldots, k$. Thus, since $y(t) \in [0, t]$, the spectral radius

$$1 \geq \rho(VD[y_j]) \geq \frac{t_m}{2} \rho(VD[\alpha_j]),$$

by Prop. 2.1 contradicting $\lim_{m \to \infty} t_m = \infty$. Therefore, equation (32) holds.

By equation (32), there exists $\varepsilon > 0$ so small that it satisfies

$$\varepsilon < \min_j \alpha_j \quad \text{and} \quad \limsup_{t \to \infty} \frac{1}{t} \langle 1|y \rangle < \langle 1|\alpha \rangle - k\varepsilon.$$

Next, (33) implies the existence of $T > 0$ large enough so that whenever $t > T$ we have

$$\alpha_j - \alpha_i e^{-v_{i,j}} t > \varepsilon \quad \text{for all} \quad i, j.$$
and

\[\forall t > T \quad \exists j' \text{ such that } \frac{y_{j'}(t)}{t} < \alpha_{j'} - \varepsilon.\]

Next, for a given \( t > T \), we show that if \( \frac{y_i(t)}{t} < \alpha_i - \varepsilon \) for some \( j \), then for all \( i \) such that \( v_{i,j} > 0 \), we have

\[\frac{y_i(t)}{t} < \alpha_i - \varepsilon.\]

Indeed, equations (31) and (34) yield

\[\frac{y_i(t)}{t} = \alpha_i e^{-t(e_i|v|\alpha - y_i/t)} \leq \alpha_i e^{-tv_{i,j}(\alpha_j - y_j/t)} < \alpha_i e^{-v_{i,j}t} < \alpha_i - \varepsilon.\]

Hence, by (35) and irreducibility of \( V \), for all \( t > T \), we have

\[\frac{y_i(t)}{t} < \alpha_i - \varepsilon \quad \text{for all } i.\]

Together, equations (31) and (36) imply

\[\frac{y_i(t)}{t} \leq \alpha_i e^{-tv_{i,j}(\alpha_j - y_j/t)} < \alpha_i e^{-v_{i,j}t} \quad \text{for all } t > T \quad \text{and all } i, j.\]

Thus, by irreducibility of \( V \), we have \( \lim_{t \to \infty} \frac{y_i(t)}{t} = 0 \) exponentially fast for each \( i = 1, \ldots, k. \)

3. Vector-Multiplicative Coalescent Processes

In this section we will analyze Smoluchowski coagulation equations (37) and modified Smoluchowski equations (39). In Lemma 3.1, we will show that equations (39) are a hydrodynamic limit of the Marcus-Lushnikov process for the vector-multiplicative coalescent. Our main result is in Subsection 3.3, where we will use tools from combinatorics and linear algebra to find a complete solution to the modified Smoluchowski system of equations (39).

3.1. Vector-Multiplicative Smoluchowski Equations. Consider a vector-multiplicative coalescent process introduced in Subsection 1.1. Let \( \zeta_x(t) \) be an averaged quantity that tracks the relative number of clusters of weight \( x \) at time \( t \geq 0 \). Since the process evolves according to the merger rates \( n^{-1}\langle x|V|y \rangle \), the Smoluchowski coagulation system of equations for the vector-multiplicative coalescent process is written as follows:

\[\frac{d}{dt}\zeta_x(t) = -\zeta_x \sum_y \zeta_y \langle x|V|y \rangle + \frac{1}{2} \sum_{y,z:y+z=x} \langle y|V|z \rangle \zeta_y \zeta_z\]

with the initial conditions \( \zeta_x(0) = \sum_{i=1}^k \alpha_i \delta_{e_i,x} \). Functions \( \zeta_x \) are indexed by all weight vectors \( x \in \mathbb{Z}_+^k \) satisfying \( \langle x|1 \rangle > 0 \). This is also the domain for summation, i.e., \( \sum_{x} f(x) = \sum_{x \in \mathbb{Z}_+^k: \langle x|1 \rangle > 0} f(x). \)
Note that the initial conditions $\zeta(0) = \sum_{i=1}^{k} \alpha_i \delta_{e_i, x}$ yield $\sum_{x} \zeta(0) = |\alpha|$. Equation (37) implies

$$\frac{d}{dt} \sum_{x} \zeta(x)|x| = -\sum_{x} \zeta(x)|x| \sum_{y} \zeta(y)|V|y|y| + \frac{1}{2} \sum_{y,z} \langle y|V|z\rangle \zeta(y|z|z + y) = 0$$

whenever the second order moments of the solutions $\zeta(x)(t)$ of (37) are convergent, i.e., the matrix of all second order moments $A(t) = \sum_{x} \zeta(x)|x|\langle x| has all finite entries.

If we set the total mass constant by letting

$$\sum_{y} \zeta(y)|y| = |\alpha|,$$

in the right hand side of (37), then equation (37) will turn into the following quasilinear system of equations

$$\frac{d}{dt} \zeta(x)(t) = -\zeta(x)|x|\langle x| + \frac{1}{2} \sum_{y,z} \langle y|V|z\rangle \zeta(y|z|z),$$

with the same initial conditions $\zeta(0) = \sum_{i=1}^{k} \alpha_i \delta_{e_i, x}$ as in (37). Equations of the type in (39) are called *modified Smoluchowski equations* (MSE) or *Flory system of equations*.

Equation (38) implies that the solutions of Smoluchowski coagulation equations (37) and modified Smoluchowski equations (39) will coincide as long as the second order moments $A(t) = \sum_{x} \zeta(x)|x|\langle x|$ of the solutions $\zeta(x)(t)$ of (37) are convergent, i.e., for all $t$ between $0$ and $t_c$, where

$$t_c = \inf \left\{ t > 0 : \sum_{x} \zeta(x)|x|\langle x|$ diverges $\right\}.$$
Lemma 3.1. For any given $T > 0$ and all $x \in \mathbb{Z}_+^k$ satisfying $\langle x|1 \rangle > 0$, $$\lim_{n \to \infty} \sup_{s \in [0,T]} \left| n^{-1} \zeta_x^n(s) - \zeta_x(s) \right| = 0 \quad \text{a.s.}$$ where $\zeta_x(t)$ is the solution of the modified Smoluchowski coagulation system \eqref{eq:modified_smoluchowski} with the initial conditions $\zeta_x(0) = \sum_{i=1}^k \alpha_i \delta_{e_i,x}$.

Proof. The proof is an application of the weak convergence results of T. G. Kurtz for density dependent population processes. Namely, Theorem 2.1 in Chapter 11 of \cite{Kurtz1975}, or equivalently, Theorem 8.1 in \cite{Kurtz1981}. This lemma follows immediately from the approach in Section 5 of \cite{Kovchegov2004} by replacing $V = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ with any other nonnegative irreducible symmetric matrix $V \in \mathbb{R}^{k \times k}$. \hfill $\Box$

3.3. Solving the Modified Smoluchowski Equations. Recall that $\alpha^x = \alpha_1^{x_1} \alpha_2^{x_2} \cdots \alpha_k^{x_k}$. The following proposition generalizes the approach in \cite{Kovchegov2004}.

Proposition 3.2. Consider \begin{equation} \zeta_x(t) = \alpha^x S_x e^{-\langle x|V|\alpha \rangle t \langle x|1 \rangle - 1}. \end{equation} with $S_x$ solving the following recursion \begin{equation} S_x(\langle x|1 \rangle - 1) = \frac{1}{2} \sum_{y,z:y+z=x} \langle y|V|z \rangle S_y S_z \end{equation} with the initial conditions $S_{e_j} = 1$ for all $j = 1, \ldots, k$. Then, $\zeta_x(t)$ is the unique solution of $\text{MSE} \ \eqref{eq:modified_smoluchowski}$ with the initial conditions $\zeta_x(0) = \sum_{i=1}^k \alpha_i \delta_{e_i,x}$.

Proof. First we show that $\zeta_x(t)$ is a solution of \eqref{eq:modified_smoluchowski}. Differentiating with respect to $t$ yields \begin{align*} \frac{d}{dt} \zeta_x(t) &= \alpha^x S_x \left[ e^{-\langle x|V|\alpha \rangle t \langle x|1 \rangle - 1} (\langle x|1 \rangle - 1) t^{\langle x|1 \rangle - 2} - \langle x|V|\alpha \rangle e^{-\langle x|V|\alpha \rangle t \langle x|1 \rangle - 1} \right] \\
&= \alpha^x S_x e^{-\langle x|V|\alpha \rangle t (\langle x|1 \rangle - 1) t^{\langle x|1 \rangle - 2} - \langle x|V|\alpha \rangle \zeta_x(t)}, \end{align*} and for $y + z = x$, \begin{align*} \zeta_y(t) \zeta_z(t) &= \alpha^y \alpha^z S_y S_z e^{-\langle y|V|\alpha \rangle t \langle y|1 \rangle + \langle z|V|\alpha \rangle t \langle z|1 \rangle - 2} \\
&= \alpha^x S_y S_z e^{-\langle x|V|\alpha \rangle t \langle x|1 \rangle - 2}. \end{align*} Plugging the above two equations into \eqref{eq:modified_smoluchowski} yields \eqref{eq:solution}. Finally, the uniqueness of solution \eqref{eq:solution} of \eqref{eq:modified_smoluchowski} follows from quasilinearity of \eqref{eq:modified_smoluchowski}. \hfill $\Box$

Next, we complete the solution of \eqref{eq:modified_smoluchowski} by finding a combinatorial expression for $S_x$ in \eqref{eq:solution}. First, we need the following notations.

For a given $x \in \mathbb{Z}_+^k$ satisfying $\langle x|1 \rangle > 0$, let $K_x(V)$ denote a graph equipped with edge weights such that...
\( \mathbf{K}_{\mathbf{x}}(V) \) is a complete graph with \( \langle \mathbf{x}|\mathbf{1} \rangle \) vertices; its vertices are partitioned into \( k \) groups with the number of vertices in the \( i \)-th partition set equal to \( x_i \), the \( i \)-th coefficient of the vector \( \mathbf{x} \);

- \( V \) is the matrix of edge weights, i.e., the weight of an edge connecting a vertex in the \( i \)-th partition set with a vertex in the \( j \)-th partition set equals \( v_{ij} = v_{ji} \).

Finally, if \( T \) is a spanning tree of \( \mathbf{K}_{\mathbf{x}}(V) \), then the weight of \( T \) is the product of the weights of all of its edges. Let \( T_\mathbf{x} = T_\mathbf{x}(V) \) denote the weighted spanning tree enumerator of \( \mathbf{K}_{\mathbf{x}}(V) \), i.e., \( T_\mathbf{x} \) is the sum of weights of all spanning trees of \( \mathbf{K}_{\mathbf{x}}(V) \). Now, for a graph consisting of just one vertex, the weighted spanning tree enumerator is set to be equal 1. Thus, \( T_{e_j} = 1 \) for all \( j = 1, \ldots, k \).

**Lemma 3.3.** Let \( T_\mathbf{x} \) be the weighted spanning tree enumerator of \( \mathbf{K}_{\mathbf{x}}(V) \). Then,

\[
S_\mathbf{x} = \frac{T_\mathbf{x}}{\mathbf{x}!},
\]

where we denote \( \mathbf{x}! = x_1!x_2! \ldots x_k! \)

is the solution to the recursion equation \((41)\).

**Proof.** Let us count the total weight \( T_\mathbf{x} = T_\mathbf{x}(V) \) of all spanning trees of \( \mathbf{K}_{\mathbf{x}}(V) \). For a given \( \mathbf{y} \) and \( \mathbf{z} \) satisfying \( \mathbf{y} + \mathbf{z} = \mathbf{x} \), there are

\[
\binom{x_1}{y_1} \binom{x_2}{y_2} \cdots \binom{x_k}{y_k}
\]

ways of splitting \( \mathbf{K}_{\mathbf{x}}(V) \) into \( \mathbf{K}_{\mathbf{y}}(V) \) and \( \mathbf{K}_{\mathbf{z}}(V) \). Each of the two subgraphs, \( \mathbf{K}_{\mathbf{y}}(V) \) and \( \mathbf{K}_{\mathbf{z}}(V) \) has the respective weighted spanning tree enumerators \( T_\mathbf{y} \) and \( T_\mathbf{z} \). For any given dissection of \( \mathbf{K}_{\mathbf{x}}(V) \) into \( \mathbf{K}_{\mathbf{y}}(V) \) and \( \mathbf{K}_{\mathbf{z}}(V) \), the total weight of the edges connecting the two subgraphs equals \( \langle \mathbf{y}|\mathbf{V}|\mathbf{z} \rangle \). Now, there are \( \langle \mathbf{x}|\mathbf{1} \rangle - 1 \) edges in every spanning tree of \( \mathbf{K}_{\mathbf{x}}(V) \), and each edge splits the tree into two spanning trees, \( \mathbf{K}_{\mathbf{y}}(V) \) and \( \mathbf{K}_{\mathbf{z}}(V) \). Hence, the total weight \( T_\mathbf{x} \) of all spanning trees in \( \mathbf{K}_{\mathbf{x}}(V) \) satisfies

\[
T_\mathbf{x} = \frac{1}{2(\langle \mathbf{x}|\mathbf{1} \rangle - 1)} \sum_{\mathbf{y},\mathbf{z},\mathbf{y}+\mathbf{z} = \mathbf{x}} \binom{x_1}{y_1} \binom{x_2}{y_2} \cdots \binom{x_k}{y_k} \langle \mathbf{y}|\mathbf{V}|\mathbf{z} \rangle T_\mathbf{y} T_\mathbf{z},
\]

where the multiple of \( \frac{1}{2} \) accounts for double counting \( \mathbf{y} + \mathbf{z} \) splits with \( \mathbf{z} + \mathbf{y} \) splits.

Equation \((42)\) can be rewritten as

\[
\frac{T_\mathbf{x}}{\mathbf{x}!} (\langle \mathbf{x}|\mathbf{1} \rangle - 1) = \frac{1}{2} \sum_{\mathbf{y},\mathbf{z},\mathbf{y}+\mathbf{z} = \mathbf{x}} \langle \mathbf{y}|\mathbf{V}|\mathbf{z} \rangle \frac{T_\mathbf{y}}{\mathbf{y}!} \frac{T_\mathbf{z}}{\mathbf{z}!}
\]

with the initial conditions \( T_{e_j} = 1 \) for all \( j = 1, \ldots, k \). Therefore, by the uniqueness of the solution of the recursive equation \((41)\), we have \( S_\mathbf{x} = \frac{T_\mathbf{x}}{\mathbf{x}!} \). \( \square \)

Let \( \mathbf{L}_{\mathbf{x}} = \mathbf{L}_{\mathbf{x}}(V) \) denote the weighted Laplacian matrix of \( \mathbf{K}_{\mathbf{x}}(V) \), i.e., \( \mathbf{L}_{\mathbf{x}} = (l_{r,s}) \in \mathbb{R}^{\langle \mathbf{x}|\mathbf{1} \rangle \times \langle \mathbf{x}|\mathbf{1} \rangle} \) is a matrix with coordinates

\[
l_{r,s} = \begin{cases} 
\langle e_i|\mathbf{V}|\mathbf{x} \rangle - v_{i,i} & \text{if } r = s, \text{ where } i = 1 + \max\{m : s_m < r\}, \\
-v_{i,j} & \text{if } r \neq s, \text{ where } i = 1 + \max\{m : s_m < r\}, \ j = 1 + \max\{m : s_m < s\},
\end{cases}
\]
where $s_0 = 0$, and $s_m = \sum_{i=1}^{m} x_i$ for $m = 1, \ldots, k$. Schematically, $L_x$ is represented as follows

$$
L_x = \begin{pmatrix}
    \langle e_1 | V | x \rangle - v_{1,1} & -v_{1,2} & \cdots & -v_{1,k} \\
    -v_{2,1} & \langle e_2 | V | x \rangle - v_{2,2} & \cdots & -v_{2,k} \\
    \vdots & \vdots & \ddots & \vdots \\
    -v_{k,1} & -v_{k,2} & \cdots & \langle e_k | V | x \rangle - v_{k,k}
\end{pmatrix}
$$

Notice that for each $m = 1, 2, \ldots, k$ and each $j = s_{m-1}+1, \ldots, s_m$, vector $|e_j\rangle - |e_{j+1}\rangle \in \mathbb{R}^{|x|}$ is an eigenvector of $L_x$ corresponding to the eigenvalue $\langle e_m | V | x \rangle$. Hence, $\langle e_m | V | x \rangle$ is an eigenvalue of $L_x$ of multiplicity $x_m - 1$.

The weighted spanning tree enumerator $T_x = T_x(V)$ can be expressed via the celebrated Kirchhoff’s Weighted Matrix-Tree Theorem [16, 17, 23] as stated below.

**Theorem 3.4 (Weighted Matrix-Tree Theorem).** For any $1 \leq i, j \leq |x|$, 

$$
T_x = (-1)^{i+j} \det [L_x]_{i,j},
$$

where $[L_x]_{i,j}$ denotes the $(i, j)$ minor of $L_x$ obtained by removing the $i$-th row and $j$-th column in $L_x$.

Observe that for a simple graph $G$ with all edge weights $w_{i,j} = 1$, the weighted spanning tree enumerator $\tau(G, w_{i,j})$ counts the number of spanning trees in $G$.

**Example 3.5.** In the 1-D case ($k = 1$), $T_n = n^{n-2}$ is the number of spanning trees in a complete graph $K_n$, and equation (42) turns into the following well known identity

$$
T_n = \frac{1}{2(n-1)} \sum_{m=1}^{n} \binom{n}{m} m(n-m)T_mT_{n-m}.
$$

On the other hand, as discovered in [24], $S_n = \frac{n^{n-2}}{m}$. Thus, validating Lemma 3.3.

**Example 3.6.** Let $V = |1\rangle|1\rangle - |I\rangle$. In the context of the vector-multiplicative coalescent processes, this is the case when only the pairs of particles of different types are allowed to bond, each such pair bonding with rate $1/n$. Then, $T_x = T_x(V)$ is the number of spanning trees in a complete multipartite graph $K_{x_1, ..., x_k}$. It was shown in [22] that the number of spanning trees in the complete multipartite graph equals

$$
T_x = n_x^{k-2} \prod_{i=1}^{k} (n_x - x_i)^{x_i-1}, \quad \text{where} \quad n_x = \langle x | 1 \rangle.
$$

For instance, in the 2-D case ($k = 2$), $T_{x_1, x_2} = x_1^{x_2-1} x_2^{x_1-1}$ is the number of spanning trees in the complete bipartite graph $K_{x_1, x_2}$ with the partitions of sizes $x_1$ and $x_2$. Also, it was shown in [18] that the solution $S_{x_1, x_2}$ of (11) equals $S_{x_1, x_2} = \frac{x_2^{x_2-1} x_1^{x_1-1}}{x_1 x_2}$. Thus, Lemma 3.3 is validated for this case as well.
Weighted Matrix-Tree Theorem (Thm. 3.4) was enhanced in S. Klee and M. T. Stamps [17] as follows.

**Lemma 3.7 (Weighted Matrix-Tree Lemma, [17]).** For any given vectors \( a, b \in \mathbb{R}^{(x|1)} \) such that

\[
\langle a | 1 \rangle = \sum_i a_i \neq 0 \quad \text{and} \quad \langle b | 1 \rangle = \sum_i b_i \neq 0,
\]

the weighted spanning tree enumerator equals

\[
T_x = \frac{\det \left( L_x + |a\rangle \langle b| \right)}{\langle a | 1 \rangle \langle b | 1 \rangle}.
\]

Lemma 3.7 will be used in our solution for \( T_x(V) \) in Thm. 3.8. Notice that in \( K_x(V) \), the total weight of all edges connecting vertices in the \( i \)-th partition with the vertices in the \( j \)-th partition equals \( x_i x_j v_{i,j} \). Thinking of the \( k \) partitions as \( k \) vertices in the partition graph \( K_k \), where vertex \( i \) and vertex \( j \), representing the corresponding partitions, are connected by an edge of weight \( x_i x_j v_{i,j} \), the weighted enumerator for the spanning trees on the partition graph equals

\[
\tau(K_k, x_i x_j v_{i,j}) = T_1(D[x_i] V D[x_i]).
\]

Notice that, by Weighted Matrix-Tree Theorem (Thm. 3.4),

\[
T_1(D[x_i] V D[x_i]) = (-1)^{i+j} \det \left[ L(x_i x_j v_{i,j}) \right]_{i,j} \quad \text{for all} \quad 1 \leq i, j \leq k,
\]

where the weighted Laplacian for the partition graph equals

\[
L(x_i x_j v_{i,j}) = D[x_i] \left( D[|e_i| V x] - V D[x_i] \right).
\]

Our next result reduces the computation of \( T_x(V) \) from \( (|x|1) - 1 \)-dimensional determinants as in (46) and (48), where \( |x|1 \) gets arbitrarily large, to just computing the \( (k - 1) \)-dimensional determinant in (50).

**Theorem 3.8 (Solution for \( T_x(V) \)).**

\[
T_x(V) = \frac{\tau(K_k, x_i x_j v_{i,j})}{x^k(Vx)^{k-1}}.
\]

**Proof.** Recall that we let \( s_0 = 0 \), and \( s_m = \sum_{i=1}^{m} x_i \) for \( m = 1, \ldots, k \). Set \( |a\rangle = \sum_{j=s_{k-1}+1}^{s_k} |e_j\rangle \) in \( \mathbb{R}^{(|x|1)} \), i.e.,

\[
\langle a | = (0, \ldots, 0, 1, \ldots, 1),
\]

and let

\[
\langle b | = (\underbrace{v_{k,1}, \ldots, v_{k,1}}_{x_1}, \underbrace{v_{k,2}, \ldots, v_{k,2}}_{x_2}, \ldots, \underbrace{v_{k,k}, \ldots, v_{k,k}}_{x_k}).
\]

Then, by Lemma 3.7

\[
T_x = \frac{\det \left( L_x + |a\rangle \langle b| \right)}{\langle a | 1 \rangle \langle b | 1 \rangle} = \frac{\det \left( L_x + |a\rangle \langle b| \right)}{x_k \langle e_k | V x \rangle}.
\]
On the other hand,

\[
L_x + \langle a \rangle \langle b \rangle = \begin{bmatrix}
  Q & * & * & * \\
  * & * & * & * \\
  * & * & * & * \\
  * & * & * & *
\end{bmatrix},
\]

where \( s_{k-1} \times s_{k-1} \) matrix \( Q = \left[ L_x \right]_{[1:s_{k-1}] \times [1:s_{k-1}]} \) is the restriction of the Laplacian matrix \( L_x \) to the first \( s_{k-1} \) rows and columns.

Equations (52) and (53) yield

\[
T_x = \frac{\langle e_k | V | x \rangle^{x_k-1}}{x_k} \det(Q).
\]

Recall the weighted Laplacian

\[
L(x_i, x_j | v_{i,j}) = D[x_i] \left( D[\langle e_i | V | x \rangle] - V D[x_i] \right).
\]

Therefore, by Thm. 3.4, the weighted enumerator for the spanning trees on the partition graph equals

\[
\tau(K_k, x_i, x_j | v_{i,j}) = \det \left[ L(x_i, x_j | v_{i,j}) \right]_{k,k} = \left( \prod_{j=1}^{k-1} x_j \right) \det(\bar{Q}),
\]

where \( \bar{Q} = \left[ D[\langle e_i | V | x \rangle] - V D[x_i] \right]_{k,k} \) is the \((k,k)\) minor of \( D[\langle e_i | V | x \rangle] - V D[x_i] \).

Next, we compare matrix

\[
\bar{Q} = \begin{bmatrix}
  \langle e_1 | V | x \rangle & -x_1 v_{1,1} & -x_2 v_{1,2} & \cdots & -x_{k-1} v_{1,k-1} \\
  -x_1 v_{2,1} & \langle e_2 | V | x \rangle & -x_2 v_{2,2} & \cdots & -x_{k-1} v_{2,k-1} \\
  \vdots & \vdots & \ddots & \ddots & \vdots \\
  -x_1 v_{k-1,1} & -x_2 v_{k-1,2} & \cdots & \langle e_{k-1} | V | x \rangle & -x_{k-1} v_{k-1,k-1}
\end{bmatrix}
\]

to

\[
Q = \begin{bmatrix}
  \langle e_1 | V | x \rangle - v_{1,1} & -v_{1,1} & -v_{1,2} & \cdots & -v_{1,k-1} \\
  -v_{1,1} & -v_{1,1} & -v_{1,2} & \cdots & -v_{1,k-1} \\
  -v_{2,1} & -v_{2,2} & \langle e_2 | V | x \rangle - v_{2,2} & \cdots & -v_{2,k-1} \\
  \vdots & \vdots & \ddots & \ddots & \vdots \\
  -v_{k-1,1} & -v_{k-1,2} & \cdots & \langle e_{k-1} | V | x \rangle - v_{k-1,k-1} & -v_{k-1,k-1}
\end{bmatrix}
\]

First, we observe that if \( |u| = (u_1, \ldots, u_{k-1})^T \) is a right eigenvector of \( \bar{Q} \), then

\[
\begin{bmatrix}
  u_1, u_1, u_2, \ldots, u_2, \ldots, u_{k-1}, \ldots, u_{k-1}
\end{bmatrix}
\]

is a right eigenvector of \( Q \) corresponding to the same eigenvalue.
is an eigenvector of $Q$ corresponding to the same eigenvalue.

Next, we find all $s_{k-1} - (k-1) = \sum_{m=1}^{k-1} (x_m - 1)$ remaining eigenvalues. This is easy since for each $m = 1, \ldots, k-1$ and each $j = s_{m-1}+1, \ldots, s_m$, vector $|e_j\rangle - |e_{j+1}\rangle$ in $\mathbb{R}^{sk-1}$ is an eigenvector of $Q$ corresponding to the eigenvalue $\langle e_m|V|x\rangle$. Thus, $\langle e_m|V|x\rangle$ is an eigenvalue of $Q$ of multiplicity $x_m - 1$.

Therefore,

$$\det(Q) = \det(\tilde{Q}) \prod_{m=1}^{k-1} \langle e_m|V|x\rangle^{x_m-1}. \quad (56)$$

Together, equations (56) and (55) imply

$$\det(Q) = T_1(D[x_i]VD[x_i]) \prod_{j=1}^{k-1} x_j^{-1} \prod_{m=1}^{k-1} \langle e_m|V|x\rangle^{x_m-1}. \quad (57)$$

Finally, substituting equation (57) into (54) yields

$$T_x = T_1(D[x_i]VD[x_i]) \prod_{j=1}^{k} x_j^{-1} \prod_{m=1}^{k} \langle e_m|V|x\rangle^{x_m-1} = \frac{T_1(D[x_i]VD[x_i])}{x^1} (Vx)^{-1}. \quad (58)$$

Thus, by (49), the proof is complete. \qed

Remark 3.9. Observe that Theorem 3.8 reduces the need for calculating $T_x(\cdot)$ for every $x \in \mathbb{Z}_+^k$ to finding an expression for $T_1(\cdot)$, and substituting values of $x$ into $T_1(D[x_i]VD[x_i]).$

Example 3.10. For a given vector $w \in (0, \infty)^k$, let

$$V = |w\rangle\langle w| - D[w_1^2].$$

Then, $K_x(V)$ is a complete multipartite graph with weighted edges. Now,

$$D[x_i]VD[x_i] = |xw\rangle\langle xw| - D[x_i^2w_1^2],$$

where $|xw\rangle = \sum_{i=1}^{k} x_iw_i|e_i\rangle$ denotes the vector with coordinates $x_iw_i$. Thus, the weighted Laplacian of the partition graph equals

$$L(x_i^jw_i) = \langle x|w\rangle D[x_i]w_i - |xw\rangle\langle xw|$$

and, by Lemma 3.7

$$\tau(K_k, x_i^jw_i) = \frac{\det(L(x_i^jw_i) + |xw\rangle\langle xw|)}{|1xw|^2} = x^1w^1 \langle x|w\rangle^{k-2}. \quad (58)$$

Hence, by Theorem 3.8, substituting (58) into (51) yields

$$T_x = w^1 \langle x|w\rangle^{k-2} (Vx)^{x-1}. \quad (59)$$

Notice that letting $w = 1$ in (59) yields (47) as a special case.
Together, Proposition 3.2, Lemma 3.3, and Theorem 3.8 yield the following general solution to the modified Smoluchowski equations (39).

**Corollary 3.11.**

\[ \zeta_x(t) = \frac{1}{x!} \alpha^x T_x e^{-(|V|^\alpha)t} (|x|_1-1) \]  

is the unique solution of MSE (39).

Finally, we would like to make the following general observation.

**Remark 3.12.** Notice that identity (46) with \( T_n = n^{n-2} \) is an application of Abel’s binomial identity. In the 2-D case \( (k = 2) \), for \( V = |1\rangle\langle 1| - I \), the expression for weighted enumerator \( T_{x_1, x_2} = x_1^{x_2-1}x_2^{x_1-1} \) can be obtained from a two dimensional generalization of Abel’s identity in Huang and Liu [11]. See [18]. Thus, the multinomial equation (42) can be considered as a \( k \)-dimensional generalization of Abel’s identity of the kind considered by A. Kelmans and A. Postnikov in [15], J. Pitman in [25], and in related works. Specifically, by Theorem 3.8, for all nonnegative irreducible \( V \), we have

\[ \tau(K_k, x_i x_j v_{i,j}) = \frac{1}{2(|1| - 1)} \sum_{y,z} \frac{x!}{y!z!} \langle y | V | z \rangle \tau(K_k, y_i y_j v_{i,j}) \tau(K_k, z_i z_j v_{i,j}). \]

4. **Gelation**

In the vector-multiplicative processes the total mass \( \sum_x \zeta_x(t) |x\rangle \) is also a vector with each coordinate being the corresponding component-wise total mass. Consider the matrix of all second order moments \( A(t) = \sum_x \zeta_x(t) |x\rangle\langle x| \). In this section, we will analyze \( \sum_x \zeta_x(t) |x\rangle \) and \( A(t) \) and establish gelation and find the gelation time.

4.1. **Divergence of second order moments.** Let \( \zeta_x(t) \) be a solution to MSE (39). Then, (39) implies \( \zeta_x(t) \geq 0 \) for all \( x \) and all \( t \geq 0 \). For \( n \in \mathbb{N} \), let

\[ |M_n(t)\rangle = \sum_{x: |1| |x| \leq n} \zeta_x(t) |x\rangle \]  

and

\[ A_n(t) = \sum_{x: |1| |x| \leq n} \zeta_x(t) |x\rangle\langle x| \]
be the partial sums for the vector series $\sum_{x} \zeta_x(t) |x\rangle \langle x|$ and matrix series $A(t) = \sum_{x} \zeta_x(t) |x\rangle \langle x|$. Equation (39) yields the following inequality

$$\frac{d}{dt} |M_n(t)\rangle = - \sum_{x:|x| \leq n} \zeta_x(t) |x\rangle \langle x| V |\alpha\rangle + \frac{1}{2} \sum_{y,z:|y+z| \leq n} \langle y| V |z\rangle \zeta_y \zeta_z |y+z\rangle$$

$$= - A_n(t) V |\alpha\rangle + \sum_{y,z:|y+z| \leq n} \zeta_y |y\rangle \langle y| V |z\rangle \zeta_z$$

$$< - A_n(t) V |\alpha\rangle + \sum_{y:|y| \leq n} \zeta_y |y\rangle \langle y| V |z\rangle \zeta_z$$

$$= - A_n(t) V |\alpha\rangle + A_n(t) V |M_n(t)\rangle$$

$$= - A_n(t) V |\alpha - M_n(t)\rangle,$$

(62)

where $|M_n(0)\rangle = |\alpha\rangle$. Inequality (62) implies

$$|M_n(t)\rangle \leq |\alpha\rangle \quad \forall t \geq 0.$$

Therefore,

$$\sum_{x:|x| \leq n} \zeta_x(t) \leq \langle 1| M_n(t)\rangle \leq \langle 1| \alpha\rangle$$

and series

$$\sum_{x} \zeta_x(t)$$

is convergent for all $\alpha \in (0, \infty)^k$ and all $t \geq 0$.

Let $S(z) = \sum_{x} S_x z^x$ be the generating function of $S_x$ defined as a $k$-dimensional power series. Notice that by (10) we have

$$\zeta_x(t) = \alpha^x S_x e^{-(|x| V |\alpha\rangle t)} |x\rangle |1\rangle^1 - 1 = \frac{1}{t} S_x \left( \sum_{j=1}^{k} \alpha_j t e^{-(|e_j| V |\alpha\rangle t)} |e_j\rangle \right)^x = \frac{1}{t} S_x w^x,$$

(63)

where $|w\rangle = \sum_{j=1}^{k} \alpha_j t e^{-(|e_j| V |\alpha\rangle t)} |e_j\rangle$.

Therefore, since

$$\sum_{x} \zeta_x(t) = \frac{1}{t} \sum_{x} S_x w^x$$

converges for all choices of $\alpha \in (0, \infty)^k$ and all $t > 0$, the series $\sum_{x} S_x w^x$ converges for all $w$ in the domain $D$ as in (10). Hence, by (11), open set

$$D_0 = \left\{ u \in (0, \infty)^k : \exists z \in R_0 \text{ such that } |u\rangle = \sum_{j=1}^{k} z_j e^{-(|e_j| V |z\rangle)} |e_j\rangle \right\}.$$

is a subset of the domain (interior region) of convergence of $S(z) = \sum_{x} S_x z^x$. 
Lemma 4.1. Solutions of (37) and (39) coincide for $0 \leq t \leq \frac{1}{\rho(V D[\alpha_i])}$. Moreover,

\[
\sum_x \zeta_x(t) |x| = |\alpha| \text{ for all } 0 \leq t < \frac{1}{\rho(V D[\alpha_i])}.
\]

Proof. Observe that for all multinomials $p(x) = p(x_1, \ldots, x_k)$, the series $\sum x p(x) S_x z^x$ is convergent in the domain of convergence of $S(z) = \sum x S_x z^x$. Thus, by (63), series

\[
\sum_x p(x) \zeta_x(t) = \frac{1}{t} \sum_x p(x) S_x w^x \quad \text{with} \quad |w| = \sum_{j=1}^k \alpha_j t e^{-(|e_j| V |\alpha t| |e_j|)}
\]

converges whenever $w \in D_0$. This happens when $\alpha t \in R_0$, i.e., when

\[t < \frac{1}{\rho(V D[\alpha_i])} \]

Since $p(x)$ can be taken to be quadratic, the matrix of all second order moments $A(t) = \sum_x \zeta_x(t) |x| \langle x \rangle$ is finite when $t < \frac{1}{\rho(V D[\alpha_i])}$. Hence, equation (38) implies that $\sum_x \zeta_x(t) |x| = |\alpha|$ for all $0 \leq t < \frac{1}{\rho(V D[\alpha_i])}$.

Additionally, equation (37) implies

\[
\frac{d}{dt} A(t) = \frac{1}{2} \sum_{y,z} \langle y | V | z \rangle \zeta_y(t) \zeta_z(t) \left( \langle y + z | y + z \rangle - \sum_{x,y} \langle x | V | y \rangle \zeta_x(t) \zeta_y(t) \langle x | x \rangle \right)
\]

\[
= \frac{1}{2} \sum_{y,z} \langle y | V | z \rangle \zeta_y(t) \zeta_z(t) \left( \langle y | z \rangle + |z| \langle y | y \rangle \right) = \sum_{y,z} \langle y | V | z \rangle \zeta_y(t) \zeta_z(t) \langle y | z \rangle
\]

\[
= \left( \sum_y \zeta_y(t) |y| \langle y \rangle \right) V \left( \sum_z \zeta_z(t) |z| \langle z \rangle \right) = A(t) V A(t),
\]

and therefore,

\[
\frac{d}{dt} (V A(t)) = (V A(t))^2
\]

with the initial conditions $A(0) = D[\alpha_i]$. Note that we used finiteness of some third order moments of $\zeta_x(t)$. However, they should be finite for all positive $t < \frac{1}{\rho(V D[\alpha_i])}$ as $p(x)$ can be take to be a third degree multinomial.

Naturally, equation (65) has the following solution

\[
A(t) = D[\alpha_i] \left( I - t V D[\alpha_i] \right)^{-1}
\]

implying the explosive behavior of the second moments matrix $A(t)$ as $t \uparrow \frac{1}{\rho(V D[\alpha_i])}$.
4.2. Gelation via mass conservation and mass dissipation. As a consequence of multidimensional Lambert-Euler inversion, \( \sum_x \zeta_x(t|x) \) can be expressed via the minimal solution \( y(t) \) of (12).

**Lemma 4.2.** Let \( \zeta_x(t) \) denote the solution to the modified Smoluchowski equation (39) and \( y(t) = \Lambda_V \circ \Psi_V(\alpha t) \) be the minimal solution of (12). Then,

\[
\sum_x \zeta_x(t|x) = \frac{1}{t} |y(t)|, \quad \text{or equivalently,} \quad \sum_x x_i \zeta_x(t) = \frac{y_i(t)}{t} \quad (i = 1, \ldots, k).
\]

**Proof.** Consider the generating function \( S(z) = \sum_x S_x z^x \) of \( S_x \) for \( z \in \mathbb{R}^k \) in the domain of convergence. Recall that, by (63), we have the following representation

\[
\zeta_x(t) = \frac{1}{t} S_x w^x, \quad \text{where} \quad |w| = \sum_{j=1}^k \alpha_j t e^{-(e_j|V|\alpha t)} |e_j|.
\]

Therefore,

\[
\zeta_x(t) x_i = \frac{1}{t} x_i S_x w^x = \frac{1}{t} w_i \frac{\partial}{\partial w_i} S_x w^x,
\]

and

\[
\sum_x \zeta_x(t|x) = \frac{1}{t} D[w] |\nabla S(w)| \quad \text{with the gradient of} \ S(z) \ \text{taken at} \ w.
\]

Thus, by Lemma 4.1 we have

\[
t |\alpha\rangle = D[w] |\nabla S(w)|, \quad \text{where} \quad |w| = \sum_{j=1}^k \alpha_j t e^{-(e_j|V|\alpha t)} |e_j|,
\]

for any choice of \( \alpha > 0 \) and \( 0 < t < \frac{1}{\rho(V D[\alpha])} \).

Hence, for all \( y \in R_0 \), we have

\[
|y| = D[w] |\nabla S(w)|, \quad \text{where} \quad |w| = \sum_{j=1}^k y_j e^{-(e_j|V|y)} |e_j|.
\]

Next, for a given \( \alpha > 0 \) and \( t \neq \frac{1}{\rho(V D[\alpha])} \), let \( y(t) = \Lambda_V \circ \Psi_V(\alpha t) \) be the minimal solution of (12). Then, we have

\[
\sum_x \zeta_x(t|x) = \frac{1}{t} D[w] |\nabla S(w)|,
\]

where, by (12),

\[
|w| = \sum_{j=1}^k \alpha_j t e^{-(e_j|V|\alpha t)} |e_j| = \sum_{j=1}^k y_j e^{-(e_j|V|y(t))} |e_j|
\]

and as \( y(t) \in R_0 \), (67) yields

\[
D[w] |\nabla S(w)| = |y(t)|.
\]
Therefore,
\[ \sum_x \zeta_x(t)|x\rangle = \frac{1}{t} D[w_i] \nabla S(w) \]
affirming the statement of the lemma for \( t \neq \frac{1}{\rho(V D[\alpha_i])} \).

Now, equation (62) implies that the partial sums \( |M_n(t)|x\rangle \) of \( \sum_x \zeta_x(t)|x\rangle \) are decreasing, and therefore, \( \sum_x \zeta_x(t)|x\rangle \) itself is coordinate-wise nonincreasing. Thus, \( \sum_x \zeta_x(t)|x\rangle \leq |\alpha\rangle \), and by continuity of \( y(t) = \Lambda_V \circ \Psi_V(\alpha t) \), we have
\[ |\alpha\rangle = \lim_{t \downarrow 1} \frac{1}{t} |y(t)\rangle = \lim_{t \downarrow 1} \frac{1}{t} \sum_x \zeta_x(t)|x\rangle \leq \sum_x \zeta_x \left( \frac{1}{\rho(V D[\alpha_i])} \right) |x\rangle \leq |\alpha\rangle. \]
This yields \( \sum_x \zeta_x(t)|x\rangle = |\alpha\rangle = \frac{1}{t} |y(t)\rangle \) for \( t = \frac{1}{\rho(V D[\alpha_i])} \). □

Gelation time \( T_{gel} \) is defined as the time until which the mass \( \sum_x \zeta_x(t)|x\rangle \) is conserved, and after which, the mass begins to dissipate coordinate-wise.

**Definition 4.3.** The gelation time is the infimum
\[ T_{gel} = \inf \left\{ t > 0 : \sum_x \zeta_x(t)|x\rangle < |\alpha\rangle \right\}. \]

Together, Corollary 2.6 and Lemma 4.2 imply the following.

**Corollary 4.4.** Let \( \zeta_x(t) \) be the solution to the modified Smoluchowski equation (39). Then, gelation time equals
\[ T_{gel} = \frac{1}{\rho(V D[\alpha_i])}. \]

Recall another critical time introduced in Subsection 3.1
\[ t_c = \inf \left\{ t > 0 : A(t) = \sum_x \zeta_x(t)|x\rangle \langle x| \text{ diverges} \right\}. \]

From Lemma 4.2 and equation (68) we deduce the value of \( t_c \).

**Corollary 4.5.** For \( \zeta_x(t) \) solving the modified Smoluchowski equation (39),
\[ t_c = \frac{1}{\rho(V D[\alpha_i])}. \]

**Proof.** Equation (38) yields \( \sum_x \zeta_x(t)|x\rangle = |\alpha\rangle \) for all \( t \in [0, t_c) \). Thus, Lemma 4.2 implies \( t_c \leq \frac{1}{\rho(V D[\alpha_i])} \). On the other hand, the second moment matrix series \( A(t) = \sum_x \zeta_x(t)|x\rangle \langle x| \) is finite for \( t < \frac{1}{\rho(V D[\alpha_i])} \) (recall (66) and its derivation), yielding \( t_c \geq \frac{1}{\rho(V D[\alpha_i])} \). □

Lemmas 2.7 and 4.2 yield another important corollary, stating that the total mass \( \sum_x \zeta_x(t)|x\rangle \) will eventually dissipate to nothing, corresponding to a fact that all smaller clusters will be eventually absorbed by a giant component.
Corollary 4.6. Let $\zeta_x(t)$ be the solution to the modified Smoluchowski equation \eqref{eq:smoluchowski}. Then,

$$\lim_{t\to\infty} \sum_x \zeta_x(t)|x| = 0.$$ 

5. APPLICATION IN MINIMAL SPANNING TREES

For a nonnegative irreducible symmetric matrix $V \in \mathbb{R}^{k \times k}$ and a vector $\alpha \in (0, \infty)^k$, let $\alpha[n]$ be as in \eqref{eq:alpha}. Consider the graph $K_{\alpha[n]}$ equipped with random edge lengths $\ell_e$ as defined in Sect. 1.2. Recall that the length of a tree is the sum of the lengths of the tree’s edges, and let the random variable $L_n$ denote the length of the minimal spanning tree of $K_{\alpha[n]}$. We are interested in the asymptotic mean lengths of the minimal spanning tree of $K_{\alpha[n]}$ as $n \to \infty$. The following theorem follows immediately from Sect. 4.3 in \cite{18}.

Theorem 5.1.

\begin{equation}
\lim_{n \to \infty} E[L_n] = \sum_x \int_0^\infty \zeta_x(t) \, dt,
\end{equation}

where $\zeta_x(t)$ is the solution of the modified Smoluchowski coagulation system \eqref{eq:smoluchowski}.

Proof. Follows immediately from the proof in Section 4.3 of \cite{18} by replacing $V = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ with any other nonnegative irreducible symmetric $V \in \mathbb{R}^{k \times k}$. \qed

Applying Corollary 3.11 and Theorem 5.1 together results in the following closed form expression for the limit $\lim_{n \to \infty} E[L_n]$.

Corollary 5.2.

\begin{equation}
\lim_{n \to \infty} E[L_n] = \sum_x \frac{(\langle x|1 \rangle - 1)!}{x!} \alpha^x T_x \langle x|V|\alpha \rangle^{-\langle x|1 \rangle} - \langle x|1 \rangle \Gamma(\langle x|1 \rangle)
\end{equation}

with $T_x = \frac{T(K_k, x^i x_j^i, x^i)}{x^1} (Vx)^{x-1}$.

Proof. Substituting $\zeta_x(t) = \frac{1}{x!} \alpha^x T_x e^{-\langle x|V|\alpha \rangle t \langle x|1 \rangle - \langle x|1 \rangle}$ from equation \eqref{eq:zeta} into equation \eqref{eq:mean} yields

$$\lim_{n \to \infty} E[L_n] = \sum_x \frac{1}{x!} \alpha^x T_x \int_0^\infty e^{-\langle x|V|\alpha \rangle t \langle x|1 \rangle - \langle x|1 \rangle} \, dt = \sum_x \frac{1}{x!} \alpha^x T_x \langle x|V|\alpha \rangle^{-\langle x|1 \rangle} \Gamma(\langle x|1 \rangle).$$ \qed

Now, we will use the following example to validate the general formula \eqref{eq:mean} in Corollary 5.2.
Example 5.3. Let $V = |1\rangle\langle 1| - I$, i.e., $K_{\alpha[n]}$ is a complete multipartite graph with edge lengths $\ell_e$ uniformly distributed on $(0, 1)$. Substituting (47) into (69) yields

$$\lim_{n \to \infty} E[L_n] = \sum_{x} \frac{(n_{x} - 1)!}{x!} \alpha^{x} n_{x}^{k - \frac{2}{x}} (n_{x} \langle 1|\alpha \rangle - \langle x|\alpha \rangle)^{-n_{x}} \prod_{i=1}^{k} (n_{x} - x_{i})^{x_{i} - 1},$$

where $n_{x} = \langle x|1 \rangle$. In the equipartitioned case, when $\alpha = 1$, equation (70) simplifies to

$$\lim_{n \to \infty} E[L_n] = \sum_{x} \frac{n_{x}!}{x!} n_{x}^{k - n_{x} - 3} (k - 1)^{-n_{x}} \prod_{i=1}^{k} (n_{x} - x_{i})^{x_{i} - 1}$$

Now, by the Abel's type multinomial identity from Abramson [1], we have

$$\sum_{x: \langle x|1 \rangle = n} \frac{n_{x}!}{x!} \prod_{i=1}^{k} (n - x_{i})^{x_{i} - 1} = k(k - 1)^{n-1} n^{k-1}$$

Substituting (72) into (71), we get

$$\lim_{n \to \infty} E[L_n] = \frac{k}{k - 1} \sum_{n=1}^{\infty} n^{-3} = \frac{k}{k - 1} \zeta(3),$$

where $\zeta(n)$ is Riemann zeta function. Equation (73) matches the general expression for the asymptotic limit $\lim_{n \to \infty} E[L_n]$ for regular graphs with i.i.d. uniformly distributed edge lengths as derived in Beveridge et al [4], thus, validating the general formula (69) in Corollary 5.2.
