Abstract

In this article, the three-dimensional Magnetohydrodynamics flow of a nanofluid over a horizontal non-linearly stretching sheet in bilateral directions under boundary layer approximation is addressed. A two-phase model has been used for the nanofluid. The influences of thermophoresis, Brownian motion and thermal radiation on heat and mass transfers are considered. Two different cases for the heat and mass transfers are studied. In the first case, uniform wall temperature and zero nanoparticles flux due to thermophoresis are considered. In the second case, prescribed heat and mass fluxes at the boundary are considered. By using the appropriate transformations, a system of non-linear partial differential equations along with the boundary conditions is transformed into coupled non-linear ordinary differential equations. Numerical solutions of the self-similar equations are obtained using a Runge–Kutta method with a shooting technique. Our results for special cases are compared with the available results in the literature, and the results are found to be in good agreement. It is observed that the pertaining parameters have significant effects on the characteristics of flow, heat and mass transfer. The results are presented and discussed in detail through illustrations.

Keywords: nanofluid, thermophoresis, Brownian motion, thermal radiation, power-law index

AMS 2010 codes: 76D10, 65L10, 35Q79

1 Introduction

Boundary layer flow over a stretching surface has various trade and technical applications, such as metal and polymer extrusion, paper production, and many others.

Also, it has important applications in engineering and manufacturing processes. Such processes are wire and fibre covering, foodstuff dispensation, heat-treated materials travelling between a feed roll and a wind-up roll or materials manufactured by extrusion, glass fibre production, cooling of metallic sheets or electronic chips,

crystal growing, drawing of plastic sheets and so on. The quality of the final product with the desired features in these processes depends on the degree of freezing in the process and the process of stretching.

Flow past a linearly stretching sheet was first studied analytically by Crane (1970). Gupta and Gupta (1977) mentioned that in all realistic situations, the stretching mechanism is not linear. Later on, several investigators, Hamad and Pop (2010), Turkyilmazoglu (2013), Pal and Mandal (2015), Waqas et al. (2016), studied such type of flow problems either with heat or with mass transfer effects.

The main characteristic of nanofluid (a combination of nanoparticles having size 1–50 nm and liquid) is to improve the base fluid’s thermal conductivity. Usually, ethylene glycol, oil, water, and so on are taken as base fluids that have limited heat transfer properties due to their low thermal conductivity. By adding nanoparticles into the base fluid, Masuda et al. (1993) first detected the change in viscosity and thermal conductivity of such fluids. The abnormal increase in the thermal conductivity occurs by the dispersion of nanoparticle, which was first observed by Choi and Eastman (1995). In case of nanofluids, Buongiorno (2006) studied the convective heat transfer and indicated that the Brownian motion, thermophoresis as the most important means for the unpredicted heat transfer augmentation. Later on, different aspects of nanofluid flow were addressed by several researchers. Considering heat and mass transfer, Das (2012) pointed out the slip effects in nanofluid flow. By the finite element method, Rana and Bhargava (2012) studied the nanofluid flow towards a non-linearly stretched surface. Nadeem and Lee (2012) studied the steady nanofluid flow over an exponentially stretched sheet. Considering the convective boundary condition (CBC), Mustafa et al. (2013) discussed nanofluid flow over an exponentially stretched surface. Using the Jeffrey’s model for non-Newtonian fluid, Nadeem et al. (2014) investigated nanofluid flow over a stretching surface to obtain a numerical solution. Magneto hydrodynamics (MHD) plays a great role in several areas particularly in geophysics, medicine, engineering and many others [Hayat et al. (2016)]. Magneto nanofluids have significant applications in drug delivery, cancer therapy, enhancement of magnetic resonance and magnetic cell separation (Hayat et al. 2016). In 2013, Khan et al. analysed the effects of a magnetic field, applied externally on nanofluid flow due to a stretching sheet considering a non-similar solution of the problem. Influences of the magnetic field on Cu-water flow were analysed by Sheikholeslami et al. (2014). Using the Buongiorno’s model, in 2016, Sheikholeslami and his co-authors described the unsteady flow of nanofluid in the presence of a magnetic field. Ma et al. (2019) studied the consequences of the magnetic field on forced convection Ag-MgO nanofluid flow in a channel with heat transfer. Many other research papers on nanofluid with magnetic field effects can be found in the studies conducted by Ma et al. (2019) and Bhatti et al. (2018).

Thermal radiation affects the heat transfer characteristics significantly particularly in control of heat transfer, space technology and high-temperature processes (Das et al. 2014). Hayat et al. (2016) reported the combined effects due to Joule heating and solar emission on MHD thixotropic nanofluid flow. Radiative flows in companies with the external magnetic fields have wider applications in nuclear engineering, power technology, astrophysics, power generation and so on (Hayat et al. 2016).

The investigations described above are two-dimensional. Three-dimensional problem being more realistic and has already drawn the attention of several researchers. Wang (1984) first addressed the three-dimensional flow due to a bidirectional stretching sheet. Ariel (2007) obtained the solution for a three-dimensional flow caused by a stretching surface using a perturbation technique. Liu and Andersson (2008) analysed the heat transport of a 3-D flow due to a stretching surface. Ahamad and Nazar (2011) discussed the MHD 3-D flow of a viscoelastic fluid due to a stretching surface. In 2013, Hayat and his co-authors considered 3-D Oldroyd-B fluid flow past a stretching surface with a CBC. Considering the exponential temperature distribution, 3-D flow and heat transfer of a viscous fluid were investigated by Liu et al. (2013). Nadeem et al. (2013) analysed the 3-D Casson fluid flow due to a linearly stretching sheet in the presence of a magnetic field. Khan et al. (2014) obtained analytical and numerical solutions for a three-dimensional flow caused by a non-linearly stretching sheet. Khan et al. (2015) investigated three-dimensional flow of a nanofluid past a non-linearly stretching sheet and highlighted its applications to the solar energy industry. Existence of two solutions was reported by Raju et al. (2016) for flow due to a non-linearly stretching sheet. Considering thermal radiation and heat
generation/absorption, Shehzad et al. (2016) analysed 3-D MHD flow of a Jeffrey nanofluid over a bidirectional stretching sheet.

The combined effects of MHD and thermal radiation on three-dimensional non-linear convective Maxwell nanofluid flow owing to a stretching sheet were reported by Hayat et al. (2017). The literature review reveals the fact that there is not so much work has been done on three-dimensional nanofluid flow caused by a non-linearly stretching sheet.

Motivated by this, in this article, we investigate the radiative heat transport of the MHD flow of a nanofluid past a stretching sheet with power-law velocity in two directions. The mathematical representations of the nanofluid model proposed by Buongiorno (2006) reflecting the contribution of nanoparticle volume fraction were used. This model also includes the effects of thermophoresis and the Brownian motion. The main objective here is to analyse the heat transport features of the flow of a nanofluid owing to the collective influences of magnetic field and radiation. Two different cases are considered: In Case I, uniform surface temperature is considered. Due to thermophoresis, a flux of nanoparticles volume fraction at the sheet is assumed to be zero. Suitable similarity transformations are considered to transform the highly non-linear partial differential equations into ordinary ones. Numerical results are obtained by a Runge–Kutta method with a shooting technique. For a clear understanding of the flow and heat transport characteristics, the obtained results are analysed in detail with their physical interpretation through Tables and Figures. It is observed that the physical parameters affect the heat and mass transport significantly.

2 Mathematical modelling

Let us consider a 3-D steady boundary layer nanofluid flow past a non-linearly stretching surface. In a usual notation, the governing equations of the problem can be written as

\[
\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0
\]

\[
\left(1\right)
\]

\[
\frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z} = \frac{\partial^2 u}{\partial z^2} - \frac{\sigma B_0^2}{\rho_f} u
\]

\[
\left(2\right)
\]

\[
\frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} + w \frac{\partial v}{\partial z} = \frac{\partial^2 v}{\partial z^2} - \frac{\sigma B_0^2}{\rho_f} v
\]

\[
\left(3\right)
\]

\[
\frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} + w \frac{\partial T}{\partial z} = \alpha \frac{\partial^2 T}{\partial z^2} - \frac{1}{(\rho c)_f} \frac{\partial q_r}{\partial z} + \frac{(\rho c)_p}{(\rho c)_f} \left[ \frac{D_B}{T_\infty} \frac{\partial C}{\partial z} + \frac{D_T}{T_\infty} \left( \frac{\partial T}{\partial z} \right)^2 \right]
\]

\[
\left(4\right)
\]

\[
\frac{u \frac{\partial C}{\partial x} + v \frac{\partial C}{\partial y} + w \frac{\partial C}{\partial z}}{D_B} = \frac{D_B \frac{\partial^2 C}{\partial z^2}}{T_\infty} + \frac{D_T \frac{\partial^2 T}{\partial z^2}}{T_\infty}
\]

\[
\left(5\right)
\]

where the components of velocity in the \(x, y\) and \(z\) directions are \(u, v\) and \(w\), respectively; kinematic viscosity is \(\nu\), electrical conductivity is \(\sigma\), \(\rho_f\) is the density, \(T\) denotes the temperature of the fluid, \(\alpha\) denotes the thermal diffusivity, \(B_0 = a/(x + y)^{1-n}\) represents the variable magnetic field, the effective heat capability of the nanoparticles is \((\rho c)_p\), and \((\rho c)_f\) is the effective heat capability of nanofluid; \(D_B, D_T\) are the diffusion coefficients due to the Brownian motion and the thermophoresis, respectively; \(q_r\) represents the radiative heat flux, \(C\) is the nanoparticle volume fraction and \(T_\infty\) is the steady temperature of the inviscid free stream.

Using the Rosseland approximation, the expression for radiative heat flux can be written as

\[
q_r = -\frac{4 \sigma \epsilon}{3 \kappa_c} T^4 \frac{\partial T}{\partial z}
\]

\[
\left(6\right)
\]
where $\sigma_v$ and $k_v$ are the Stefan–Boltzmann constant and the mean absorption coefficient, respectively. This investigation is restricted to the optically bulky fluid. For sufficiently small temperature difference linearisation of Eq. (6) can be performed. Using the Taylor’s series expansion for $T^4$ about $T_\infty$ and ignoring the higher-order terms, we get

$$T^4 = 4T^3T_\infty - 3T^4_\infty.$$

A. Boundary conditions for fluid flow

The boundary conditions can be written as

$$u = u_w = a(x+y)^n, \quad v = v_w = b(x+y)^n, \quad w = 0 \quad \text{and as } z \to \infty, u \to 0, v \to 0 \quad (7)$$

$u_w$ and $v_w$ denote the velocities of stretching along the $x$ and $y$ directions, respectively, and $n$ is a non-linearly stretching parameter and $C_w$ is the uniform volume fraction for the nanoparticles in the inviscid free stream.

B. Boundary conditions for heat, mass transport

There are different types of heating process that specify the temperature distribution on the surface and ambient fluid. These are constant or prescribed wall temperature (CWT or PWT); constant or prescribed surface heat flux (CHF or PHF), CBC and Newtonian heating. In this problem, we have considered two cases of temperature distributions: CWT and CHF separately. Moreover, different methods are available for the active or passive control of nanoparticles, namely, constant or prescribed concentration at the wall (CHF or PWC); zero mass or normal flux of nanoparticles at the surface (ZMF); constant or prescribed mass flux (CMF or PMF). In this problem, two different boundary conditions, ZMF and CMF for mass transfer, are considered.

Therefore, the conditions at the boundary for temperature, volume fraction for nanoparticles are

Case I:

$$T = T_w, \quad D_B \frac{\partial C}{\partial z} + D_T \frac{\partial T}{\partial z} = 0 \text{ at } z = 0 \text{ (CWT, ZMF) & } T \to T_\infty, C \to C_w \text{ as } z \to \infty \quad (8a)$$

Case II:

$$\frac{\partial T}{\partial z} = \frac{T_w}{\alpha}, \quad \frac{\partial C}{\partial z} = \frac{C_w}{D_B} \quad \text{at } z = 0 \text{ (CHF, CMF) & } T \to T_\infty, C \to C_w \text{ as } z \to \infty \quad (8b)$$

where $T_w$ and $C_w$ are the temperature and concentration at the surface, respectively.

Let us define the similarity variable and similarity transformations as

$$\eta = \sqrt{\frac{a}{v}} (x+y)^{\frac{n-1}{2}} z,$$

$$u = a(x+y)^n f'(\eta), \quad v = a(x+y)^n g'(\eta), \quad w = -\sqrt{av(x+y)^{n-1}} \left[ \frac{n+1}{2} (f+g) + \frac{n-1}{2} \eta \left( f' + g' \right) \right], \quad (9a)$$

$$\theta(\eta) = \frac{T-T_\infty}{T_w-T_\infty}, \quad \frac{\phi}{C_w} = \frac{C-C_w}{C_w} \quad \text{(for Case-I)}$$

$$T = T_\infty + \frac{T_w}{\alpha} \left( \frac{v}{a(n+1)(x+y)^{n-1}} \right)^{\frac{1}{2}} \theta(\eta), \quad C = C_w + \frac{C_w}{D_B} \left( \frac{v}{a(n+1)(x+y)^{n-1}} \right)^{\frac{1}{2}} \phi(\eta) \quad (9b)$$

(for Case-II).

Using these transformations in Eqs (1)–(5) and also using the relation given by Eq. (6), we get the following self-similar equations

$$f''' + \frac{n+1}{2} (f+g) f'' - n(f' + g') f' - M f' = 0 \quad (11)$$
Dimensionless wall shear stresses, heat and mass fluxes are

\[ \tau' = 0 \text{ as } \eta \to \infty \]  
\[ \phi' = 0 \text{ as } \eta \to \infty \]  
\[ \theta' = 0 \text{ as } \eta \to \infty \]  
\[ \theta = 0 \text{ as } \eta \to \infty \]  

Dimensionless wall shear stresses, heat and mass fluxes are

\[ C_{fx} = \frac{\tau_{xx}}{\rho_f u_w}, \quad C_{fy} = \frac{\tau_{xy}}{\rho_f v_w^2}, \quad N_u = \frac{(x+y)q_w}{k(T_w-T_e)}, \quad \text{Sh} = \frac{(x+y)j_w}{D_B(C_w-C_e)} \]

where \( \tau_{xx} \) and \( \tau_{xy} \) are shear stresses at the wall and \( q_w \) represents the heat flux at the wall, \( j_w \) denotes the mass flux which are described as

\[ \tau_{xx} = \mu \left( \frac{\partial u}{\partial z} + \frac{\partial w}{\partial x} \right)_{z=0}, \quad \tau_{xy} = \mu \left( \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \right)_{z=0}, \quad q_w = -k \left( \frac{\partial T}{\partial y} \right)_{z=0}, \quad j_w = -D_B \left( \frac{\partial C}{\partial y} \right)_{z=0}. \]

Finally, we get

\[ C_{fx}Re_x^{1/2} = f''(0), \quad C_{fy}Re_y^{1/2} \lambda^{3/2} = g''(0), \quad NuRe_x^{-1/2} = -\theta'(0), \quad ShRe_x^{-1/2} = -\phi'(0) \]

where the Reynolds numbers (local) along the directions of \( x, y \) are \( Re_x = \frac{u_w(x+y)}{v_f} \) and \( Re_y = \frac{u_w(x+y)}{v_f} \), respectively. The far field component of velocity may be written in the form

\[ w(x,t,\infty) = -\sqrt{av_y(x+y)^{n-1}} \frac{n+1}{2} [f(\infty) + g(\infty)] \]

The differential Eqs (11)–(14) are coupled and non-linear. Equations (11)–(14), together with the conditions (15a–15d), form a two-point boundary value problem. By converting it into an initial value problem, those equations are numerically solved using the Runge–Kutta method and the shooting technique by choosing an appropriate value for \( n_{\text{sc}} \).

2.1 Special cases

(i) For \( \lambda = 0 \), the aforementioned equations represent the case of a 2-D flow.

(ii) For \( \lambda = 1 \), the system leads to the axisymmetric nanofluid flow owing to a non-linearly stretched surface.

3 Results and interpretations

3.1 Testing of numerical results

To test the validity of our numerical results, an assessment is made with the available results from the open literature for some special cases and presented in Table 1. Table 1 shows a complete agreement of our results with those of Khan et al. (2015) and Raju et al. (2016) in the absence of the magnetic field and thermal radiation.

Grid independence test has been performed and presented through Table 2, which shows that the values of \( f''(0) \), \( g''(0) \) are the same for two different grid sizes (0.01, 0.03).

3.2 Analysis of the results

To obtain in-depth features, the numerical results are presented graphically in Figures 2–12.

Figures 2(a–f) depict the effects of magnetic field on velocity components along with the directions of \( x \) and \( y \) axes, temperature and concentration fields. Linearly \((n = 1)\) and non-linearly stretching \((n = 3)\) cases are considered. As the Lorentz force (which resists the movement of fluid) increases (increase in magnetic parameter \( M \)), the velocity in both directions decreases [Figures 2(a,b)]. This result is similar to that of Mahanthesh et al. (2016). But with an increase in the magnetic field, an increase in temperature in the cases of CWT [Figure 2(c)] and PHF [Figure 2(d)] and concentration in the cases of ZMF [Figure 2(e)] and PMF [Figure 2(f)] is observed. The effect of the magnetic field on the temperature field is more pronounced in the PHF case. Owing to the occurrence of an externally applied magnetic field resistance to the stream is created, and as a result, it transformed some energy to heat energy. Consequently, the temperature increased with an increase in \( M \) [Figures
Concentration increases in the vicinity of the surface and rises to a maximum before it starts to decay and finally vanishes due to the thermophoresis effect [Figure 2(e)] in the case of ZMF. The nanoparticle volume fraction at the wall is negative, which can be verified by the boundary condition $\varphi'(0) = -\frac{N_t}{N_b} \theta'(0)$. This is quite obvious, and similar results can be found in Kuznetsov and Nield (2014), and Mustafa et al. (2015). From these figures, it is also noticed that an increase in the parameter $n$ (power-law index), velocities in both directions, temperature and concentration decrease.

From Figures 3(a–f), it is clear that the fluid velocity in the direction of $x$-axis decreases [Figure 3(a)]; but it increases significantly in the $y$-directions [Figure 3(b)] owing to augment in the parameter $\lambda$. That is, an increase in the stretching ratio parameter $\lambda$ helps to accelerate the flow in the vertical direction [Khan et al. (2015)]. Owing to the augmentation of stretching in the $y$-direction, pressure on flow increases, and hence, the temperature for both CWT [Figure 3(c)] and PHF [Figure 3(d)] cases and concentration for both ZMF [Figure 3(e)] and PMF [Figure 3(f)] cases decrease. The effect of stretching ratio parameter $\lambda$ for both linearly ($n = 1$) and non-linearly ($n = 3$) stretching cases are exhibited through the figures. A significant effect in the thermal field is noted in the PHF case compared to that of the CWT case. The mixing tendency of cold fluid with the ambient fluid along the stretched surface increases with a rise in $\lambda$ which causes to diminish the hotness of the liquid. The influence of $\lambda$ on nanoparticle volume fraction is more pronounced in the PMF case compared to that of the ZMF case. Less penetration of nanoparticle is noted due to the augment in as the speedy flow in a downward direction brushes away the nanoparticles on the way to the surface.

The effect of $n$ on velocity, temperature and concentration of the nanoparticles can be seen in Figures 4(a–d). Velocities along the directions of $x$ [Figure 4(a)] and $y$ [Figure 4(b)] are found to diminish with increasing $n$. The observation is similar to that of Khan et al. (2015) and Mahanthesh et al. (2016). As the power-law index $n$ increases, larger shear force is experienced. As a result, skin friction coefficients in both the directions are augmented due to an increase in $n$. Temperature for the PHF case [Figure 4(c)] and nanoparticle volume fraction for PMF case [Figure 4(d)] also reduce by a rise in $n$.

From Figures 5(a–d), it is seen that the temperature [Figures 5(a,b)] and nanoparticle volume fraction [Figures 5(c,d)] are increasing functions of thermophoresis parameter $N_t$: The force responsible for the diffusion of nanoparticle owing to temperature ramp is recognised. Growth in the width of the boundary layer related to the temperature field is observed for higher values of the thermophoresis parameter $N_t$ [Figures 5(a,b)]. Through a rise in $N_t$, the thermal conductivity of the nanofluid increases due to the company of nanoparticles. As a result, the concentration of the fluid increases through the rise in $N_t$ [Figures. 5(c,d)].

The influences of radiation on temperature and nanoparticle volume fraction are portrayed in Figures 6(a–d). It is observed that the temperature [Figures 6(a,b)] and the nanoparticle volume fraction [Figures 6(c,d)] both increase for a rise in $R$. As $K_r$ diminishes when the thermal radiation parameter $R$ increases, which, in turn, causes to amplify the deviation of the heat flux due to radiation. The speed of heat transport due to radiation augments and consequently the fluid temperature increases. The width of the temperature boundary layer enlarges by a rise in heat transport to the liquid due to radiation.

The effects of the Prandtl number $Pr$ on temperature and concentration fields of the nanofluid are presented in Figures 7(a–d). The thicknesses of both the boundary layers: thermal [Figures 7(a,b)] and solutal [Figures

7(c,d)] diminish for the higher values of $Pr$. Owing to an augmentation in $Pr$, the thermal diffusivity reduces, and it reduces the energy transferability.

Almost negligible effect in the temperature is seen due to changes in the Brownian motion parameter $N_b$. This agrees very well with the findings of Kuznetsov and Nield (2014) and Khan et al. (2015) for the CWT case. Due to a rise in the Brownian motion parameter $N_b$, temperature significantly increases in the PHF case [Figure 8(a)]. On the other hand, the temperature drops down with a rise in the Schmidt number $Sc$ for the PHF case [Figure 8(b)]. This effect is pronounced in the linearly stretching sheet [$n = 1$] case compared to non-linearly stretching sheet [$n = 3$] case. Reduction in the thickness of the solute boundary layer for higher values of $N_b$ is experienced in both ZMF [Figure 9(a)] and PMF [Figure 9(b)] cases. It can be seen that due to a rise in the Schmidt number $Sc$, the width of the solute boundary layer reduces in both cases of ZMF [Figure 9(c)] and PMF [Figure 9(d)]. A significant decrease in concentration is noted for the non-linearly stretching sheet ($n = 3$) case compared to the linearly stretching sheet ($n = 1$) case. Schmidt number, $Sc$, is the relation of diffusivities related to momentum and mass. A higher value of $Sc$ indicates the smaller value of coefficient $D_B$ of Brownian diffusion that opposes the nanoparticles to penetrate intensely into the liquid.

To provide a clear understanding of the flow field, the streamlines are presented for several values of $n$ in Figures 10(a,b).

Figures 11(a,b) indicate that the coefficient of the skin friction (local) in the directions of $x$, $y$ increases with increasing $\lambda$, $M$ and $n$. From Figure 11(c), it is clear that the Nusselt number in the CWT case increases due to an increase in $\lambda$ and $n$ but decreases with the magnetic field parameter $M$. However, the local Sherwood number in the ZMF case increases with the magnetic parameter $r$ but decreases with the stretching ratio parameter $\lambda$ and with the power-law index $n$. These changes are depicted in Figure 11(d).

The effects of $N_b$, $N_t$ on the Nusselt number for the CWT case and local Sherwood number for ZMF case are portrayed in Figures 12(a,b), respectively. Both are found to increase with an increase in $N_b$. On the other hand, the Nusselt number [Figure 12(a)] decreases and Sherwood number [Figure 12(b)] increases with the increasing values of $N_t$.

Table 3 shows that $-\theta'(0)$, $-\phi'(0)$ both decrease with the increasing values of the thermophoresis parameter. Also, $-\theta'(0)$ increases with the increasing Prandtl number but $-\phi'(0)$ decreases with $Pr$. 
Fig. 9 Effects of \( N_b \), the parameter for Brownian motion for (a) ZMF and (b) PMF and Schmidt number Sc for (c) ZMF and (d) PMF on nanoparticle volume fraction \( \phi(\eta) \).

Table 3 Values of \( -\theta'(0) \) and \( -\varphi'(0) \) for different values of thermophoresis parameter \( N_t \) and Prandtl number \( \text{Pr} \) with \( n = 4.0, \lambda = 0.9, N_b = 0.7, \ Pr = 2.0, R = 0.5, \ Sc = 15.0 \)

4 Concluding remarks

The current study provides solutions (numerical) for a steady MHD three-dimensional nanofluid flow past a bi-directional non-linearly stretching surface. Two types of conditions at the boundary for temperature and volume fraction for nanoparticles are considered. From the current investigation, the following observations are derived:

1. A rise in the magnetic strength causes a reduction in the resistance and the rate of heat transport.
2. Both the thermal and the concentration boundary layer thicknesses increase with an increase in the magnetic parameter in addition to the radiation parameter.
3. The volume fraction of the nanoparticles is a decreasing function of the Brownian motion parameter.
4. In the presence of thermophoresis, both temperature and volume fraction of the nanoparticles increase significantly in the boundary layer.
