Abstract  
We study the $b \to s\gamma$ decay including the next to leading QCD corrections in the two Higgs doublet model with flavor changing neutral currents at the tree level. We find the constraints to the flavor changing parameters of the model, using the experimental results on the branching ratio of $B \to X_s\gamma$ decay, provided by the CLEO Collaboration, the restrictions coming from the $\Delta F = 2$ ($F = K, D, B$) mixing and the $\rho$ parameter.

1 Introduction

Rare B meson decays are one of the most promising research areas in particle physics and lie on the focus of theoretical and experimental physicists. In the Standard Model (SM), they are induced by flavor changing neutral currents (FCNC) at loop level and therefore sensitive to the gauge structure of the theory. From the experimental point of view, they play an outstanding role in the precise determination of the fundamental parameters of the SM, such as Cabbibo-Kobayashi-Maskawa (CKM) matrix elements, leptonic decay constants, etc. Furthermore, these decays provide a sensitive test to the new physics beyond the SM, such as two Higgs Doublet model (2HDM), Minimal Supersymmetric extension of the SM (MSSM) [1], etc. Among the rare B decays, \( b \rightarrow s \gamma \) has received considerable interest since the branching ratios (Br) of the inclusive \( B \rightarrow X_s \gamma \) [2] and exclusive \( B \rightarrow K^* \gamma \) [3] have been already measured experimentally. Recently, the new experimental results for the inclusive \( b \rightarrow s \gamma \) decay are announced by CLEO and ALEPH Collaborations [4]. Therefore, the \( b \rightarrow s \gamma \) decay is under an extensive investigation in the framework of various extensions of the SM, in order to get information about the model parameters or improve the existing restrictions.

It is well known that the FCNC are forbidden at the tree level in the SM. This restriction is achieved in the extended model with the additional conditions. 2HDM is one of the simplest extensions of the SM, obtained by the addition of a new scalar \( SU(2) \) doublet. The Yukawa lagrangian causes that the model possesses phenomenologically dangerous FCNC’s at the tree level. To protect the model from such terms, the ad hoc discrete symmetry [3] on the 2HDM scalar potential and the Yukawa interaction is proposed and there appear two different versions of the 2HDM depending on whether up and down quarks couple to the same or different scalar doublets. In model I, the up and down quarks get mass via vacuum expectation value (v.e.v.) of only one Higgs field. In model II, which coincides with the MSSM in the Higgs sector, the up and down quarks get mass via v.e.v. of the Higgs fields \( H_1 \) and \( H_2 \) respectively where \( H_1(H_2) \) corresponds to first (second) Higgs doublet of 2HDM [3]. In the absence of the mentioned discrete symmetry, FCNC appears at the tree level and this model is called as model III in current literature [4, 5, 6]. A comprehensive phenomenological analysis of the model III was done in series of works [4, 5, 6, 7]. In particular, from a purely phenomenological point of view, low energy experiments involving \( K^0 - \bar{K}^0, B^0 - \bar{B}^0, K_L \rightarrow \mu \bar{\mu} \), etc, place strong constraints on the existence of tree level flavor changing (FC) transitions, existing in the model III.

In the present work, we examine the \( b \rightarrow s \gamma \) decay in the model III, taking the next to leading (NLO) QCD corrections into account, in a more detailed analysis compared to one
existing in literature (see [7, 10]). Further, we obtain the constraints for the neutral couplings \( \xi_{U_{Ntt}} \), \( \xi_{D_{Nbb}} \) and \( \xi_{U_{Ntc}} \) with the assumption that \( \xi_{D_{Ncc}} \), \( \xi_{D_{Nss}} \) and the other couplings which include the first generation indices are negligible compared to former ones (for the definition of \( \xi_{N,ij} \) see section 2). Our predictions are based on the CLEO measurement \( B \rightarrow X_s \gamma \) and the restrictions coming from the \( \Delta F = 2 \) (\( F = K, D, B \)) mixing and the \( \rho \) parameter [10]. Note that NLO QCD corrections to the \( b \rightarrow s \gamma \) decay in 2HDM (for model I and II) were calculated in [11, 12].

The paper is organized as follows: In Section 2, we present the NLO QCD corrected Hamiltonian responsible for the \( b \rightarrow s \gamma \) decay in the model III and discuss the effects of the additional \( Left – Right \) flipped operators to the decay rate. Section 3 is devoted to the constraint analysis, more precisely to the the ratios \( \frac{\xi_{U_{Ntt}}}{\xi_{D_{Nbb}}} \), \( \frac{\xi_{U_{Ntc}}}{\xi_{U_{Ntt}}} \) and our conclusions.

2 Next to leading improved short-distance contributions in the model III for the decay \( b \rightarrow s \gamma \)

Before presenting the NLO QCD corrections to the \( b \rightarrow s \gamma \) decay amplitude in the 2HDM (model III), we would like to remind briefly the main features of the 2HDM. The Yukawa interaction for the general case is

\[
\mathcal{L}_Y = \eta_i^U \bar{Q}_{iL} \tilde{\phi}_1 U_{jR} + \eta_i^D \bar{Q}_{iL} \phi_1 D_{jR} + \xi_i^U \bar{Q}_{iL} \tilde{\phi}_2 U_{jR} + \xi_i^D \bar{Q}_{iL} \phi_2 D_{jR} + h.c. \quad (1)
\]

where \( L \) and \( R \) denote chiral projections \( L(R) = \frac{1}{2}(1 \mp \gamma_5) \), \( \phi_i \) for \( i = 1, 2 \), are the two scalar doublets, \( \eta_i^U,D \) and \( \xi_i^U,D \) are the matrices of the Yukawa couplings. For convenience we choose \( \phi_1 \) and \( \phi_2 \) in the following basis:

\[
\phi_1 = \frac{1}{\sqrt{2}} \left[ \begin{array}{c} 0 \\ v + H_0 \end{array} \right] + \left( \frac{\sqrt{2}}{i} \chi_0 \right) ; \phi_2 = \frac{1}{\sqrt{2}} \left( \begin{array}{c} \sqrt{2} H_0 \\ H_1 + i H_2 \end{array} \right) , \quad (2)
\]

where the vacuum expectation values are,

\[
< \phi_1 > = \frac{1}{\sqrt{2}} \left( \begin{array}{c} 0 \\ v \end{array} \right) ; < \phi_2 > = 0 . \quad (3)
\]

This choice permits us to write the FC part of the interaction as

\[
\mathcal{L}_{Y,FC} = \xi_{i j}^U \bar{Q}_{iL} \tilde{\phi}_2 U_{jR} + \xi_{i j}^D \bar{Q}_{iL} \phi_2 D_{jR} + h.c. , \quad (4)
\]

with the following advantages:
• doublet $\phi_1$ corresponds to the scalar doublet of the SM and $H_0$ to the SM Higgs field. This part of the Yukawa Lagrangian is responsible for the generation of the fermion masses with the couplings $\eta^{U,D}$.

• all new scalar fields belong to the $\phi_2$ scalar doublet.

The couplings $\xi^{U,D}$ are the open window for the tree level FCNC’s and can be expressed for the FC charged interactions as

$$\xi_{ch}^{U} = \xi_{neutral} V_{CKM},$$
$$\xi_{ch}^{D} = V_{CKM} \xi_{neutral},$$

(5)

where $\xi^{U,D}_{neutral}$ is defined by the expression

$$\xi_{N}^{U,D} = (V_{L}^{U,D})^{-1} \xi^{U,D} V_{R}^{U,D}.$$  

(6)

Here the charged couplings appear as a linear combinations of neutral couplings multiplied by $V_{CKM}$ matrix elements. This gives an important distinction between model III and model II (I).

After this preliminary remark, let us discuss the NLO QCD corrections to the $b \to s \gamma$ decay in the 2HDM for the general case. The appropriate framework is that of an effective theory obtained by integrating out the heavy degrees of freedom, which are, in this context, $t$ quark, $W^\pm$, $H^\pm$, $H_1$, and $H_2$ bosons, where $H^\pm$ denote charged $H_1$ and $H_2$ denote neutral Higgs bosons. The LLog QCD corrections are done through matching the full theory with the effective low energy theory at the high scale $\mu = m_W$ and evaluating the Wilson coefficients from $m_W$ down to the lower scale $\mu \sim O(m_b)$. Note that we choose the higher scale as $\mu = m_W$ since the evaluation from the scale $\mu = m_{H^\pm}$ to $\mu = m_W$ gives negligible contribution to the Wilson coefficients. Here we assume that the charged Higgs boson is heavy due to theoretical analysis of the $b \to s \gamma$ decay (see [11, 13]).

The effective Hamiltonian relevant for $b \to s \gamma$ decay is

$$\mathcal{H}_{eff} = -4G_F \sqrt{2} V_{tb} V_{ts}^* \sum_i C_i(\mu) O_i(\mu),$$

(7)

where the $O_i$ are operators given in eq. (8) and the $C_i$ are Wilson coefficients renormalized at the scale $\mu$. The coefficients are calculated perturbatively and expressed as functions of the heavy particle masses in the theory.

1In all next discussion we denote $\xi_{neutral}$ as $\xi^U_N, \xi^D_N$. 

3
The operator basis depends on the model used and the conventional choice in the case of SM, 2HDM model II (I) and MSSM is

\[
O_1 = (\bar{s}_L \gamma_\mu c_{L\beta})(\bar{c}_{L\beta} \gamma^\mu b_{L\alpha}), \\
O_2 = (\bar{s}_L \gamma_\mu c_{L\alpha})(\bar{c}_{L\beta} \gamma^\mu b_{L\beta}), \\
O_3 = (\bar{s}_L \gamma_\mu b_{L\alpha}) \sum_{q=u,d,s,c,b} (\bar{q}_{L\beta} \gamma^\mu q_{L\beta}), \\
O_4 = (\bar{s}_L \gamma_\mu b_{L\beta}) \sum_{q=u,d,s,c,b} (\bar{q}_{L\beta} \gamma^\mu q_{L\alpha}), \\
O_5 = (\bar{s}_L \gamma_\mu b_{L\alpha}) \sum_{q=u,d,s,c,b} (\bar{q}_{R\beta} \gamma^\mu q_{R\beta}), \\
O_6 = (\bar{s}_L \gamma_\mu b_{L\beta}) \sum_{q=u,d,s,c,b} (\bar{q}_{R\beta} \gamma^\mu q_{R\alpha}), \\
O_7 = \frac{e}{16\pi^2} \bar{s}_\alpha \sigma_{\mu\nu}(m_b R + m_s L)b_\alpha F^{\mu\nu}, \\
O_8 = \frac{g}{16\pi^2} \bar{s}_\alpha T^a_{R\alpha\beta}\sigma_{\mu\nu}(m_b R + m_s L)b_\beta G^{\mu\nu},
\]

where \(\alpha\) and \(\beta\) are SU(3) colour indices and \(F^{\mu\nu}\) and \(G^{\mu\nu}\) are the field strength tensors of the electromagnetic and strong interactions, respectively.

In our case, however, new operators with different chirality structures can arise since the general Yukawa lagrangian includes both \(L\) and \(R\) chiral interactions. The conventional operator set is extended first adding two new operators which are left-right analogues of \(O_1\) and \(O_2\), namely

\[
O_9 = (\bar{s}_L \gamma_\mu c_{L\beta})(\bar{c}_{R\beta} \gamma^\mu b_{R\alpha}), \\
O_{10} = (\bar{s}_L \gamma_\mu c_{L\alpha})(\bar{c}_{R\beta} \gamma^\mu b_{R\beta}),
\]

Further we need the second operator set \(O'_1 - O'_{10}\) which are flipped chirality partners of \(O_1 - O_{10}\):

\[
O'_1 = (\bar{s}_R \gamma_\mu c_{R\beta})(\bar{c}_{R\beta} \gamma^\mu b_{R\alpha}), \\
O'_2 = (\bar{s}_R \gamma_\mu c_{R\alpha})(\bar{c}_{R\beta} \gamma^\mu b_{R\beta}), \\
O'_3 = (\bar{s}_R \gamma_\mu b_{R\alpha}) \sum_{q=u,d,s,c,b} (\bar{q}_{R\beta} \gamma^\mu q_{R\beta}), \\
O'_4 = (\bar{s}_R \gamma_\mu b_{R\beta}) \sum_{q=u,d,s,c,b} (\bar{q}_{R\beta} \gamma^\mu q_{R\alpha}), \\
O'_5 = (\bar{s}_R \gamma_\mu b_{R\alpha}) \sum_{q=u,d,s,c,b} (\bar{q}_{L\beta} \gamma^\mu q_{L\beta}), \\
O'_6 = (\bar{s}_R \gamma_\mu b_{R\beta}) \sum_{q=u,d,s,c,b} (\bar{q}_{L\beta} \gamma^\mu q_{L\alpha}), \\
O'_7 = \frac{e}{16\pi^2} \bar{s}_\alpha \sigma_{\mu\nu}(m_b R + m_s L)b_\alpha F^{\mu\nu},
\]
\[ O'_8 = \frac{g}{16\pi^2} \bar{s}_\alpha T^a_{\alpha\beta} \sigma_{\mu\nu}(m_b L + m_s R)b_\beta G^{a\mu\nu}, \]

\[ O'_9 = (\bar{s}_R \gamma_\mu c_{R\alpha})(\bar{c}_L \gamma^\mu b_{L\alpha}), \]

\[ O'_{10} = (\bar{s}_R \gamma_\mu c_{R\alpha})(\bar{c}_L \gamma^\mu b_{L\beta}). \]

This extended basis is the same as the basis for \( SU(2)_L \times SU(2)_R \times U(1) \) extensions of SM \[14\]. Note that in the SM, model II (I) 2HDM and the MSSM, the absence of \( O'_7 \) and \( O'_8 \) are a consequence of assumption \( m_s/m_b \sim 0 \).

In the calculations, we take only the charged Higgs contributions into account and neglect the effects of neutral Higgs bosons for the reasons given below: The neutral bosons \( H_0, H_1 \) and \( H_2 \) are defined in terms of the mass eigenstates \( \bar{H}_0, h_0 \) and \( A_0 \) as

\[ H_0 = (\bar{H}_0 \cos \alpha - h_0 \sin \alpha) + v, \]

\[ H_1 = (h_0 \cos \alpha + \bar{H}_0 \sin \alpha), \]

\[ H_2 = A_0, \]

where \( \alpha \) is the mixing angle and \( v \) is proportional to the vacuum expectation value of the doublet \( \phi_1 \) (eq. \(3\)). Here we assume that the masses of neutral Higgs bosons \( h_0 \) and \( A_0 \) are heavy compared to the \( b \)-quark mass. The neutral Higgs scalar \( h_0 \) and pseudoscalar \( A_0 \) give contribution only to \( C_7 \) for \( b \to s\gamma \) decay. With the choice of \( \alpha = 0 \), \( C_7^{h_0} \) and \( C_7^{A_0} \) can be expressed at \( m_W \) level as

\[ C_7^{h_0}(m_W) = (V_{tb} V_{ts}^*)^{-1} \sum_{i=d,s,b} \bar{\xi}_{D,i}^{\bar{D}} \xi_{N,ib}^D \frac{Q_i}{8 m_i m_b}, \]

\[ C_7^{A_0}(m_W) = (V_{tb} V_{ts}^*)^{-1} \sum_{i=d,s,b} \bar{\xi}_{D,i}^{\bar{D}} \xi_{N,ib}^D \frac{Q_i}{8 m_i m_b}, \]

where \( m_i \) and \( Q_i \) are the masses and charges of the down quarks \( (i = d, s, b) \) respectively. Here we used the redefinition

\[ \xi^{U,D} = \sqrt{\frac{4G_F}{\sqrt{2}}} \bar{\xi}^{U,D}. \]

Eq. \((12)\) shows that neutral Higgs bosons can give a large contribution to \( C_7 \), which does not respect the CLEO and ALEPH data \[14\]. At this stage we make an assumption that the couplings \( \bar{\xi}_{D,i}^{\bar{D}} (i = d, s, b) \) and \( \bar{\xi}_{S,db}^{\bar{D}} \) are negligible to be able to reach the conditions \( \bar{\xi}_{S,ib}^{\bar{D}} \xi_{N,is}^D \ll 1 \) and \( \bar{\xi}_{S,db}^{\bar{D}} \xi_{N,ds}^D \ll 1 \). These choices permit us to neglect the neutral Higgs effects.

Now, for the evaluation of Wilson coefficients, we need their initial values with standard matching computations. Denoting the Wilson coefficients for the additional charged Higgs
contribution with \( C_i^H(m_W) \), we have the initial values of the Wilson coefficients for the first set of operators (eqs. (8), (9))

\[
C_{1...9,10}^H(m_W) = 0 , \]

\[
C_7^H(m_W) = \frac{1}{m_t^2} (\xi_{N,tt}^U + \xi_{N,tc}^U \frac{V_{cs}^{*}}{V_{ts}^{*}}) (\xi_{N,tt}^D + \xi_{N,tc}^D \frac{V_{cb}}{V_{tb}}) F_1(y) , \]

\[
+ \frac{1}{m_t m_b} (\xi_{N,tt}^U + \xi_{N,tc}^U \frac{V_{cs}^{*}}{V_{ts}^{*}}) (\xi_{N,tt}^D + \xi_{N,tc}^D \frac{V_{cb}}{V_{tb}}) F_2(y) , \]

\[
C_8^H(m_W) = \frac{1}{m_t^2} (\xi_{N,tt}^U + \xi_{N,tc}^U \frac{V_{cs}^{*}}{V_{ts}^{*}}) (\xi_{N,tt}^D + \xi_{N,tc}^D \frac{V_{cb}}{V_{tb}}) G_1(y) , \]

\[
+ \frac{1}{m_t m_b} (\xi_{N,tt}^U + \xi_{N,tc}^U \frac{V_{cs}^{*}}{V_{ts}^{*}}) (\xi_{N,tt}^D + \xi_{N,tc}^D \frac{V_{cb}}{V_{tb}}) G_2(y) . \quad (14) \]

The explicit forms of the Wilson coefficients in the SM \( C_i^{SM}(m_W) \) is presented in the literature \[15\]. For the primed Wilson coefficients we get,

\[
C_i^{SM}_{1...9,10}(m_W) = 0 , \]

\[
(15) \]

\[
C_{1...9,10}^{H'}(m_W) = 0 , \]

\[
C_7^{H'}(m_W) = \frac{1}{m_t^2} (\xi_{N,bs}^D \frac{V_{tb}}{V_{ts}^{*}} + \xi_{N,ss}^D \frac{V_{ts}^{*}}{V_{tb}}) (\xi_{N,bb}^D + \xi_{N,ss}^D \frac{V_{cb}}{V_{tb}}) F_1(y) , \]

\[
+ \frac{1}{m_t m_b} (\xi_{N,bs}^D \frac{V_{tb}}{V_{ts}^{*}} + \xi_{N,ss}^D \frac{V_{ts}^{*}}{V_{tb}}) (\xi_{N,tt}^U + \xi_{N,tc}^U \frac{V_{cb}}{V_{tb}}) F_2(y) , \]

\[
C_8^{H'}(m_W) = \frac{1}{m_t^2} (\xi_{N,bs}^D \frac{V_{tb}}{V_{ts}^{*}} + \xi_{N,ss}^D \frac{V_{ts}^{*}}{V_{tb}}) (\xi_{N,bb}^D + \xi_{N,ss}^D \frac{V_{cb}}{V_{tb}}) G_1(y) , \]

\[
+ \frac{1}{m_t m_b} (\xi_{N,bs}^D \frac{V_{tb}}{V_{ts}^{*}} + \xi_{N,ss}^D \frac{V_{ts}^{*}}{V_{tb}}) (\xi_{N,tt}^U + \xi_{N,tc}^U \frac{V_{cb}}{V_{tb}}) G_2(y) , \quad (16) \]

where \( x = m_t^2/m_W^2 \) and \( y = m_t^2/m_H^2 \). The functions \( F_1(y) , F_2(y) , G_1(y) \) and \( G_2(y) \) are given as

\[
F_1(y) = \frac{y(7 - 5y - 8y^2)}{72(y - 1)^3} + \frac{y^2(3y - 2)}{12(y - 1)^4} \ln y , \]

\[
F_2(y) = \frac{y(5y - 3)}{12(y - 1)^2} + \frac{y(-3y + 2)}{6(y - 1)^3} \ln y , \]

\[
G_1(y) = \frac{y(-y^2 + 5y + 2)}{24(y - 1)^3} + \frac{-y^2}{4(y - 1)^4} \ln y , \]

\[
G_2(y) = \frac{y(-3y + 2)}{4(y - 1)^2} + \frac{y}{2(y - 1)^3} \ln y . \quad (17) \]
In calculations we neglect the small contributions of the internal $u$ and $c$ quarks compared to one due to the internal $t$ quark.

For the initial values of the mentioned Wilson coefficients in the model III (eqs. (14), (15), and (16)), we have

$$C_i^{(t)2HDM}(m_W) = C_i^{(t)SM}(m_W) + C_i^{(t)H}(m_W).$$

Using these initial values, we can calculate the coefficients $C_i^{2HDM}$ and $C_i'^{2HDM}$ at any lower scale with five quark effective theory where large logarithms can be summed using the renormalization group. Since the strong interactions preserve chirality, the operators in eqs. (8, 9) cannot mix with their chirality flipped counterparts eq. (10) and the anomalous dimension matrices of two separate set of operators are the same and do not overlap. With the above chosen initial values of Wilson coefficients, their evaluations are similar to the SM case.

For completeness, note that, the operators $O_5,O_6,O_9$ and $O_{10}$ ($O'_5,O'_6, O'_9$ and $O'_{10}$) give contributions to the matrix element of $b \rightarrow s \gamma$ and in the NDR scheme which we use here, the effective magnetic moment type Wilson coefficients are redefined as

$$C_7^{eff}(\mu) = C_7^{2HDM}(\mu) + Q_d(C_5^{2HDM}(\mu) + N_c C_6^{2HDM}(\mu)),$$

$$C_7'^{eff}(\mu) = C_7'^{2HDM}(\mu) + Q_d(C_5'^{2HDM}(\mu) + N_c C_6'^{2HDM}(\mu))$$

where $N_c$ is the color factor and $Q_u$ ($Q_d$) is the charge of up (down) quarks. There is still another mixing in the operator set $O_7, O_8, O_9, O_{10}$ ($O'_7, O'_8, O'_9, O'_{10}$) and we do not take into account since the initial values of the Wilson coefficients $C_{10}$ and $C'_{10}$ are zero in our case.

The NLO corrected coefficients $C_7^{2HDM}(\mu)$ and $C_7'^{2HDM}(\mu)$ are given as

$$C_7^{2HDM}(\mu) = C_7^{LO,2HDM}(\mu) + \frac{\alpha_s(\mu)}{4\pi} C_7^{(1)2HDM}(\mu),$$

$$C_7'^{2HDM}(\mu) = C_7'^{LO,2HDM}(\mu) + \frac{\alpha_s(\mu)}{4\pi} C_7'^{(1)2HDM}(\mu).$$

Here $\eta = \alpha_s(m_W)/\alpha_s(\mu)$, $h_i$ and $a_i$ are the numbers which appear during the evaluation. The functions $C_7^{LO,2HDM}(\mu)$ and $C_7'^{LO,2HDM}(\mu)$ are the leading order QCD corrected Wilson coefficients:

$$C_7^{LO,2HDM}(\mu) = \eta^{16/23} C_7^{2HDM}(m_W) + (8/3)(\eta^{14/23} - \eta^{16/23}) C_8'^{2HDM}(m_W).$$
and $C_7^{12HDM}(\mu)$ is the $\alpha_s$ correction to the leading order result that its explicit form can be found in [11, 12]. $C_7^{12HDM}(\mu)$ can be obtained by replacing the Wilson coefficients in $C_7^{2HDM}(\mu)$ with their primed counterparts. The NLO corrected coefficients $C_5^{2HDM}(\mu)$, $C_6^{2HDM}(\mu)$ and $C_7^{2HDM}(\mu)$, $C_8^{2HDM}(\mu)$ are numerically small at $m_b$ scale therefore we neglect them in our calculations.

Finally, the NLO QCD corrected $b \to s \gamma$ decay rate in model III is obtained as

$$\Gamma(b \to s\gamma) = \frac{G_F m_b^5}{32\pi^4} \alpha_{em} |V_{ts}V_{tb}|^2 \left( |C_7^{eff}(m_b)|^2 + |C_7^{eff}(m_b)|^2 \right),$$

where $\alpha_{em}$ is the fine structure constant, and $m_b$ is b-quark mass. $|C_7^{eff}(m_b)|^2$ is given in [11].

$$|C_7^{eff}(m_b)|^2 = |D|^2 + A + \frac{\delta_{NP}^C}{m_b^2} |C_7^{LO,2HDM}(m_b)|^2$$

$$+ \frac{\delta_{NP}^C}{m_b^2} \text{Re}\left\{ \left( C_7^{LO,2HDM}(m_b) \right)^* \left( C_2^{LO,2HDM}(m_b) - \frac{1}{6} C_1^{LO,2HDM}(m_b) \right) \right\}. \quad (23)$$

The functions $D$ and $A$ are [11].

$$D = C_7^{LO,2HDM}(m_b) + \frac{\alpha_s}{4\pi} \left( C_7^{(1)2HDM}(\mu) + \sum_i C_i^{LO,2HDM}(m_b) r_i - \frac{16}{3} C_1^{LO,2HDM}(m_b) \right),$$

$$A = \frac{\alpha_s(m_b)}{\pi} \sum_{i,j=1,i\leq j}^8 \text{Re}\left\{ C_i^{LO,2HDM}(m_b) \left( C_j^{LO,2HDM}(m_b) \right)^* f_{ij} \right\}. \quad (24)$$

The explicite expressions for $f_{ij}, r_i, \delta_{NP}^c$ and $\delta_{NP}^c$ can be found in [11]. At this point we would like to note that the expressions for unprimed Wilson coefficients in our case can be obtained from the results in [11] by the following replacements:

$$|Y|^2 \to \frac{1}{m_t^2} \left( \xi_{N,tt}^{\nu} + \xi_{N,tt}^{\tau} V_{ts}^* \right) \left( \xi_{N,tt}^{\nu} + \xi_{N,tt}^{\tau} V_{ts}^* \right),$$

$$XY \to \frac{1}{m_t m_b} \left( \xi_{N,tt}^{\nu} + \xi_{N,tt}^{\tau} V_{ts}^* \right) \left( \xi_{N,ttb}^{\nu} + \xi_{N,ttb}^{\tau} V_{tb}^* \right). \quad (25)$$

To obtain $|C_7^{eff}(m_b)|^2$, it is enough to use the primed Wilson coefficients at $m_W$ level (eq. [10]) since the evaluation of $C_7^{eff}(\mu)$ from $\mu = m_W$ to $\mu = m_b$ is the same as that of $C_7^{eff}(\mu)$.

Note that, for model II (model I) $Y$ and $XY$ are

$$Y = 1/tan^2\beta \left( 1/tan\beta \right),$$

$$XY = 1 \left( -1/tan^2\beta \right). \quad (26)$$

### 3 Constraint analysis

Now let us turn our attention to the constraint analysis. Restrictions to the free parameters, namely, the masses of the charged and neutral Higgs bosons and the ratio of the v.e.v. of the
two Higgs fields, denoted by $\tan\beta$ in the framework of model I and II, have been predicted in series of works [18]. Recently the constraint which connects masses of the charged Higgs bosons, $m_{H^\pm}$ and $\tan\beta$, is obtained by using the QCD corrected values in the LLO approximation and it is shown that the constraint region is sensitive to the renormalization scale, $\mu$ [13].

Usually, the stronger restrictions to the new couplings are obtained from the analysis of the $\Delta F = 2$ (here $F = K, B_d, D$) decays, the $\rho$ parameter and the $B \to X_s\gamma$ decay. In [10], all these processes have been analysed and two possible scenarios are obtained depending on the choice whether the constraint from $R_b^{exp}$ is enforced or not. Although the new experimental results are near the SM result, $R_b^{SM} = 0.2156$, the world average value for $R_b (= 0.21656 \pm 0.00074)$ is still almost one standard deviations higher than the SM one. This brings the possibility that an enhancement to the SM value is still necessary to get the correct experimental one. Such an enhancement is reached under the conditions $\xi_{bb}^D >> 1$ and $m_{H^\pm} \sim 400 GeV$ [10], where $\xi_{bb}^D$ is a model III parameter (see section 2) and $v$ is the vacuum expectation value of the Higgs field responsible for the generation of fermion masses.

First, the constraints for the FC couplings from $\Delta F = 2$ processes for the model III were investigated without QCD corrections, under the following assumptions [10]

1. $\lambda_{ij} \sim \lambda$
2. $\lambda_{uij} = \lambda_{dij} << 1$, $i, j = 1, 2, 3$

where $u(d)$ is up (down) quark and $i, j$ are the generation numbers.

3. case 2 and further assumption

$$\lambda_{bb} , \lambda_{sb} >> 1 \text{ and } \lambda_{tt} , \lambda_{ct} << 1.$$ (27)

In the analysis, the ansatz

$$\xi_{ij}^{UD} = \lambda_{ij} \sqrt{\frac{m_i m_j}{v}},$$ (28)

is used. Note that this ansatz coincides with the one proposed by Cheng and Sher.

Using the constraint coming from $R_b^{exp}$, the measurement $Br(B \to X_s\gamma)$, $\Delta F = 2$ mixing and the result coming from the analysis of the $\rho$ parameter, the following restrictions are obtained [10]:

$$150 GeV \leq m_{H^\pm} \leq 200 GeV,$$

$$\lambda_{bb} >> 1 , \lambda_{tt} << 1,$$

$$\lambda_{sb} >> 1 , \lambda_{ct} << 1.$$ (29)
Since the experimental results for $R_b^{exp}$ are still unclear, we disregard the constraint coming from $R_b^{exp}$ and we analyse the restrictions for the couplings $\xi_{Ntt}^U$, $\xi_{Nbb}^D$ and $\xi_{Ntc}^U$ in the NLO approximation, respecting the constraints due to the $\Delta F = 2$ mixing, the $\rho$ parameter and using the measurement by the CLEO Collaboration:

$$Br(B \to X_s\gamma) = (3.15 \pm 0.35 \pm 0.32) \cdot 10^{-4}.$$ 

Here, we explain why we use only the CLEO data in our analysis but not ALEPH one ($Br(B \to X_s\gamma) = (3.11 \pm 0.80 \pm 0.72) \cdot 10^{-4}$). The ALEPH data has a larger error compared to CLEO data and it leads to a wide restriction region for $|C_{7}^{eff}|$, which includes the one coming from the CLEO data. Therefore, the CLEO data allows us to get more stringent constraints on the model parameters.

The idea in this calculation is to take $\xi_{Ntc}^U << \xi_{Ntt}^U$, $\xi_{Nbb}^D \sim 0$, $\xi_{Nij}^D \sim 0$, where the indices $i, j$ denote $d$ and $s$ quarks. This choice permit us to neglect the neutral Higgs contributions because the Yukawa vertices are the combinations of $\xi_{Nvb}^D$ and $\xi_{Nij}^D$.

To reduce the b-quark mass dependence let us consider the ratio

$$R = \frac{Br(B \to X_s\gamma)}{Br(B \to X_c\nu\bar{\nu})} = \frac{|V_{ts}V_{tb}|^2}{|V_{cb}|^2} \frac{6\alpha_{em}}{\pi g(z)\kappa(z)} |C_{7}^{eff}|^2,$$

where $g(z)$ is the phase space factor in semileptonic b-decay, $\kappa(z)$ is the QCD correction to the semileptonic decay width [19],

$$g(z) = 1 - 8z^2 + 8z^6 - z^8 - 24z^4 \ln z,$$

$$\kappa(z) = 1 - \frac{2\alpha_s(m_b)}{3\pi}\left\{(\pi^2 - \frac{31}{4})(1 - z) + \frac{3}{2}\right\} - (0.25 - 0.18(1 - 4(1 - z^2)^4 \frac{1}{g(z)})$$

and $z = m_c/m_b$.

Using the CLEO data and following the same procedure as given in [13], we reach the possible range for $|C_{7}^{eff}|$ as

$$0.257 \leq |C_{7}^{eff}| \leq 0.439.$$  

In fig. [11], we plot the parameter $\xi_{N,tt}^U$ with respect to $\xi_{N,bb}^D$ at $\mu = 4.8 \text{ GeV}$ and $m_{H^\pm} = 400 \text{ GeV}$. We see, that there are two different restriction regions, where the upper one corresponds to the positive $C_{7}^{eff}$ value, however the lower one to the negative $C_{7}^{eff}$ value. Increasing $\xi_{N,bb}^D$ causes $|\xi_{N,tt}^U|$ to decrease in both regions. With the given value of $\xi_{N,bb}^D > > 1$, the condition $|r_{tb}| = \frac{|\xi_{N,tt}^U|}{|\xi_{N,bb}^D|} < 1$ is obtained. In the lower region it is possible that the ratio becomes
negative, i.e. \( r_{tb} = \frac{\bar{\xi}_{N,tt}^U}{\bar{\xi}_{N,bb}^D} < 0 \). Further, increasing \( m_{H^\pm} \) causes to increase \( |r_{tb}| \) and the area of the restriction region.

Fig. (2) is devoted the same dependence as in fig. (1) and shows that the third region, which is almost a straight line, appears. In this region the ratio \( r_{tb} >> 1 \) and increases with increasing \( m_{H^\pm} \) similar to the previous regions.

Finally, we consider \( \bar{\xi}_{N,tt}^U \) dependence of \( \bar{\xi}_{N,tc}^U \), which is a neutral FC coupling. In fig. (3) we plot the \( \bar{\xi}_{N,tt}^U \) dependence of \( \bar{\xi}_{N,tc}^U \) for fixed \( \bar{\xi}_{N,bb}^D = 60 \, m_b \), at \( \mu = 4.8 \, GeV \), and charged Higgs mass \( m_{H^\pm} = 400 \, GeV \). Here the selected region for \( \bar{\xi}_{N,tt}^U \) is \( 40 \leq \bar{\xi}_{N,tt}^U \leq 48 \). Increasing \( \bar{\xi}_{N,tt}^U \) forces the ratio \( r_{tc} = \frac{\bar{\xi}_{N,tc}^U}{\bar{\xi}_{N,tt}^U} \) to be negative. It is realized that the ratio \( |r_{tc}| \) becomes smaller when \( m_{H^\pm} \) is larger.

Still there is a region in which \( \bar{\xi}_{N,tc}^U \) is constrained for the possible large value of \( \bar{\xi}_{N,tt}^U \), namely \( \bar{\xi}_{N,tt}^U = 8.0 \times 10^4 \) for \( m_{H^\pm} = 400 \, GeV \):

\[
-0.24 < \bar{\xi}_{N,tc}^U < 0.24, \text{ or} \\
-3.26 < \bar{\xi}_{N,tc}^U < -3.19, \tag{33}
\]

In conclusion, we find the constraints for the Yukawa couplings \( \bar{\xi}_{N,tt}^U, \bar{\xi}_{N,bb}^D \) and \( \bar{\xi}_{N,tc}^U \) using the CLEO measurement \( Br(B \rightarrow X_s \gamma) \) and respecting the restrictions due to the \( \Delta F = 2 \) mixing and the \( \rho \) parameter (see [10] for details). The constraints for the other parameters of the model III from the existing experimental results require more detailed new analysis.
