Allostatic Load and Glaucoma: Are We Missing the Big Picture? J Curr Glaucoma Pract 2020;14(2):47–49.

Allostatic Load is assessed by markers of physiological dysregulation. These markers represent four biological systems, such as cardiovascular system, metabolic system, inflammatory system, and neuroendocrine system, and have also been described as consisting of primary mediators and secondary outcomes of stress. Allostatic load score (ALS) is one of the most well-known measures to quantitate this load. The original description of ALS included 10 parameters: systolic blood pressure, diastolic blood pressure, total cholesterol (TC), high-density lipoprotein (HDL), glycosylated hemoglobin (HbA1c), waist-to-hip ratio (WHR), dehydroepiandrosterone sulfate (DHEA-S), urinary epinephrine, urinary norepinephrine, and urinary cortisol. Each of which is converted into a dichotomous variable, with 1 point given if the biomarker is in the high-risk range (highest or lowest quartile) and 0 if not. It has been proposed that neuroendocrine and immunological parameters should be included in allostatic load measurements. There have also been variations in terms of defining the cutoff of each biomarker as well as the way total score is calculated. The total score is usually treated as a continuous variable, and higher scores represent greater allostatic load although few studies have also dichotomized the total score. Currently, there is no accepted “gold standard” measure. Some of the biomarkers that have been used in various studies are listed in Table 1.

The risk of mortality increases both with increasing age and an increase in allostatic load. Additionally, the allostatic load also increases with age and stress. Stress can modulate the exosomal contents (non-coding RNAs) and accelerate aging, and stress also activates the hypothalamic–pituitary–adrenal (HPA) axis and leads to release of glucocorticoid stress hormones, thereby further increasing the allostatic load.

Interplay between Chronic Systemic Diseases, Allostatic Load, and Glaucoma

Studies have shown a positive association between allostatic load and hypertension. The drivers of allostatic load have been identified as chronic stressors such as occupational stress, social isolation, marriage and racial discrimination, etc. Allostatic load also correlates with development of diabetes and hypercholesterolemia. In addition, allostatic load has been shown to be associated with other chronic diseases such as abdominal obesity, cardiovascular disease, arthritis, and cancer (Flowchart 1).

Older age, diabetes, hypertension, heart disease, and sickle cell anemia are systemic risk factors for glaucoma, and these systemic diseases have been directly linked to the allostatic load. In a study by Dave et al., the prevalence of diabetes mellitus and hypertension was 29.4% and 47.5%, respectively, in patients with glaucoma.

Table 1: Biomarkers used for allostatic load measurement in published literature

| S. no. | Biomarker | Remarks |
|-------|-----------|---------|
| 1     | Urinary cortisol | Primary mediator: Neuroendocrine |
| 2     | Salivary cortisol | Primary mediator: Neuroendocrine |
| 3     | Dehydroepiandrosterone sulfate (DHEA-S) | Primary mediator: Neuroendocrine |
| 4     | Urinary epinephrine | Primary mediator: Neuroendocrine |
| 5     | Urinary norepinephrine | Primary mediator: Neuroendocrine |
| 6     | Heart rate variability | Primary mediator: Neurophysiological |
| 7     | TNF-α | Primary mediator: Anti-inflammatory |

Conflict of interest: None
Other studies report that there is significant association of chronic systemic diseases such as diabetes, hypertension, coronary artery disease, obstructive sleep apnea, etc., with primary glaucoma, but their actual role as a risk factor for glaucoma needs to be further evaluated. One possible explanation is that allostatic load is an important risk factor both for systemic diseases and for glaucoma, leading to the observed association between chronic systemic diseases and glaucoma. There are various possible mechanisms by way of which allostatic load may cause or worsen glaucoma (Flowchart 1).

Chronic stress can lead to excess secretion of hormones like catecholamines and endogenous glucocorticoids like cortisol. Catecholamines can lead to vasoconstriction and decrease the blood supply to the optic nerve head and retinal ganglion cells, while cortisol can lead to an increase in IOP due to changes in the trabecular meshwork. Corticosteroids can also induce myocilin (MYOC) in trabecular meshwork, which is linked to glaucoma. The association between allostatic load and the changes it induces in ocular physiology needs our attention and warrants further investigation. Recent studies suggest that stress can cause an increase in intraocular pressure in both open angle and angle closure glaucoma, and techniques of mindfulness and relaxation can decrease it. Hence, stress can be a causal factor for a rise in intraocular pressure and also be a consequence of it which constitutes a self-perpetuating vicious cycle. Stress and allostatic overload could also be cause of worsening of intraocular pressure in previously controlled patients. Continuous stress with elevated cortisol levels and catecholamines can cause sympathetic nervous system overdrive and vascular dysregulation. This can lead to a decrease in ischemia threshold and contribute to optic neuropathy without rise in IOP (normal pressure glaucoma). Thus, stress can lead to high tension glaucoma by raising intraocular pressure through autonomic imbalance/endogenous hypercortisolism and normal tension glaucoma by vascular dysregulation. Stress also provokes chronic inflammation, raising levels TNFα and IL6, and this can be a factor contributing to RGC apoptosis due to neuro-inflammation of the glial cells. In general, glaucoma patients suffer from an impaired quality of life which may worsen further with medical/surgical therapy, and this leads to a state of allostatic overload that increases risk of other systemic diseases and mortality.

The association of allostatic load and glaucoma has important implications. After diagnosing a patient with glaucoma, ophthalmologists should make effort to evaluate the allostatic load in conjunction with a physician and suggest dietary/lifestyle interventions that reduce allostatic load may be helpful for patients with glaucoma. In this regard, lifestyle interventions, including a healthy diet, regular aerobic exercises, Yoga, and meditation, may have a significant impact in reducing this load. A meta-analysis by Pascoe et al. proved that practicing yoga asanas reduced the markers of allostatic load like cortisol, systolic blood pressure, cholesterol, and fasting blood sugar. Yoga and meditation has been inculcated as a complete stress reduction program to increase the quality of life and well-being to promote healthy aging. Meditation was found to be useful in chronic systemic diseases and has shown to improve blood sugars and blood lipid levels in type 2 diabetes mellitus patients.

Studies have shown that yoga and meditation are helpful in patients with glaucoma, and this effect may be mediated through a reduction of the allostatic load. Meditation may prevent glaucoma progression by reducing IOP through the following mechanisms: decreasing serum cortisol, increasing nitric oxide, augmenting blood flow and brain oxygenation, lowering oxidative stress, and decreasing inflammation.

Clinically, the association of allostatic load and glaucoma has important implications. After diagnosing a patient with glaucoma, ophthalmologists should make effort to evaluate the allostatic load in conjunction with a physician and suggest dietary/lifestyle interventions that reduce allostatic load may be helpful for patients with glaucoma. In this regard, lifestyle interventions, including a healthy diet, regular aerobic exercises, Yoga, and meditation, may have a significant impact in reducing this load. A meta-analysis by Pascoe et al. proved that practicing yoga asanas reduced the markers of allostatic load like cortisol, systolic blood pressure, cholesterol, and fasting blood sugar. Yoga and meditation has been inculcated as a complete stress reduction program to increase the quality of life and well-being to promote healthy aging.
modifications that reduce allostatic load, along with the prescribing of glaucoma medications. A team comprising of the glaucoma specialist, psychologist, dietician/fitness expert, and general physician may provide ideal holistic therapy for glaucoma patients. This may prove to be a useful adjunct tool for improving the quality of patients suffering from this irreversibly blinding disease and help us to widen our “target” from lowering IOP to improving the overall health of glaucoma patients.
