INTRODUCTION

Glioma incidence in India ranges from 6 to 12 per 100,000 population. Glioma tumours account for 70% of all brain tumours with astrocytoma (38.7%) being the most frequent tumour. The prognosis of high-grade gliomas is very poor and have a limited overall survival rate.

ABSTRACT

Introduction: Glial tumours account for 70% of all brain tumours with astrocytoma (38.7%) being the most frequent tumour. The prognosis of high-grade gliomas is very poor and have a limited overall survival rate.

Aim: To establish the role of p53(immunohistochemical) with histopathological grades of various glial tumours such as astrocytoma, oligodendroglioma and ependymoma.

Methods: This will be a Prospective analytical Study. The study will be carried out from 1st August 2018 to 31st July 2020 in the Histopathology division and Immunohistochemistry section in the Department of Pathology, Jawaharlal Nehru Medical College (J.N.M.C) in co-ordination with Department of Neuro-Surgery. A total of 50 resected specimens of radiologically suspected cases of Glial tumours operated in the Department of Neurosurgery will be considered for the study. The resected specimens will be grossed, processed and evaluated for histopathology and p53 expression.

Results: A direct correlation between the histopathological grade and the p53 expression will be observed.

Conclusion: High-grade gliomas exhibit high p53 expression. Thus, p53 as an adjunct to histological grade can provide a supportive clue to the clinicians to predict the biological behaviour of gliomas.

Key Words: Glial tumour, p53, Immunophenotyping
this tumour is poor and therapy such as surgery, radiation and medication are often in vain. On examination, glioblastoma may be a poorly outlined intra-axial mass with varied colored (multiform) attributed to necrosis and haemorrhage. If the tumour is nearby the centre it can travel from corpus callosum to one hemisphere to the next. Histologically, the tumour presents with nuclear atypia, hypercellularity, and high-grade mitotic activity. It also shows increased microvascular proliferation and serpentine pattern of necrosis.

The prognosis of high-grade gliomas is very poor and have a low survival rate. Gliomas are very difficult when it comes to treatment. Researchers have tried hard to understand the cell physiology and genetic alteration in the cell so we know more about the tumours and make proper effective treatment. Many oncogenes and their protein products show involvement. One of them happens to be p53. The p53 is found at the short arm of chromosome 17. The p53 gene is of two types wild type and mutant type.

With the help of immunohistochemistry, we can check for abnormal p53 in the tumour. Staining is dependent on the half-life of mutant p53. If p53 is found in the cell whether it be wild or mutant, the will show positivity.

**OBJECTIVE**

To study the histological grade of glial tumours and the immunoexpression of p53.

**MATERIALS AND METHODS**

This is prospective analytical study initiated on 1st August 2018 and completed on 31st July 2020 in the Histopathology division and Immunohistochemistry section in the Department of Pathology, Jawaharlal Nehru Medical College (J.N.M.C) in co-ordination with Department of Neuro-Surgery.

A total of 50 resected specimens of radiologically suspected cases of Glial tumours operated in the Department of Neurosurgery, A.V.B.R.H, Sawangi (Meghe), Wardha will be considered for the study. The resected specimens will be grossed, processed and evaluated for histopathology and p53 expression.

**Inclusion Criteria**

- Patients diagnosed with glial tumours on histopathology.
- Patients of both genders.
- Patients of all ages.

**Exclusion Criteria**

- Cases of glial tumours with other associated tumours diagnosed on histopathology.
- Patients on radiotherapy and chemotherapy.
- Cases of recurrence.

**Statistical Analysis**

The analysis would be carried out by using ‘Chi-square test’.

**p53 Grading by Immunohistochemistry**

The p53 grading for all the cases will be done by a single senior pathologist who will be blind to the result of histological grade of the malignancy to avoid any kind of bias.

**EXPECTED RESULTS**

The data will be put in master-chart and grouped and tabulated according to various criteria. The relationship with the p53 expression and histopathological grade of the gliomas will be assessed and studied. The sensitivity and specificity will be calculated and analysed.

**DISCUSSION**

The nuclear positivity will show the expression of p53 in the tumour.

P53 scoring system- p53 is scored from 0 to 3
- No stain in the nucleus
- 10 % stain of the nucleus
- 10-30 % stain of the nucleus
- > 30 % stain of the nucleus

The localization of the p53 gene to the short arm of chromosome 17 is of interest because there is a common pattern of loss of one the alleles in the astrocytoma of the brain. In recent past that has studied both p53 gene mutations and LOH on chromosome 17p, 65 % of tumours with p53 mutation suffer a loss of chromosome 17p. Various mutations have been found in both low and high-grade gliomas. Approximately 95% of mutations happen in those codons which are more preserved. This may cause a loss of transcription ability due to the mutated p53.

Cancers with p53 mutation show more aggressive tumour behaviour such as widespread metastasis and very less cellular differentiation. A better knowledge of the factors and mechanisms will show aggressive behaviour of some glial tumours. The discussion will be programmed to compare the discoveries of the current study with the observations available in the different studies. p53 show a variety of malignancies including brain tumours. Mutations of p53 are common phenomena of these tumours and through various studies, it has been found out that they can be encountered frequently.

Missense mutations are seen in the P53 gene. High expression of p53 can be used as a surrogate marker for p53 deactivation. However, too high expression of p53 can harm or eventually cause a response that is physiological in response
to DNA damage. The observations performed over these objectives of p53 expression will be compared with available observations in the literature for the conclusion of correlation of p53 expression with histological grade of glial tumours. Several articles related to different aspects of cancers were reviewed. Deshpande et al reported on methylation pattern of retrotransposons as a biomarker for human cancer. Mohite et al conducted an immunohistochemical evaluation of the expression pattern of p53, p63, and p73 in epithelial dysplasia. Shweta et al reflected on the immuno-expression profile of cyclin D1, Ki67 and P53 in the evaluation of endometrial hyperplasia.

**CONCLUSION**

p53 as an adjunct to histological grade can provide a supportive clue to the clinicians to predict the biological behaviour of gliomas.

**ACKNOWLEDGMENT**

Authors acknowledge the immense help received from the scholars whose articles are cited and included in references to this manuscript. The authors are also grateful to authors/editors/publishers of all those articles, journals, and books from which the literature for this article has been reviewed and discussed.
