Scrutinizing $\bar{B} \to D^*(D\pi)\ell\bar{\nu}_\ell$ and $\bar{B} \to D^*(D\gamma)\ell\bar{\nu}_\ell$

in search of new physics footprints

P. Colangelo and F. De Fazio

Abstract

Besides being important to determine Standard Model parameters such as the CKM matrix elements $|V_{cb}|$ and $|V_{ub}|$, semileptonic $B$ decays seem also promising to reveal new physics (NP) phenomena, in particular in connection with the possibility of uncovering lepton flavour universality (LFU) violating effects. In this view, it could be natural to connect the tensions in the inclusive versus exclusive determinations of $|V_{cb}|$ to the anomalies in the ratios $R(D^{(*)})$ of decay rates into $\tau$ vs $\mu, e$. However, the question has been raised about the role of the parametrization of the hadronic $B \to D^{(*)}$ form factors in exclusive $B$ decay modes. We focus on the fully differential angular distributions of $\bar{B} \to D^*\ell\bar{\nu}_\ell$ with $D^* \to D\pi$ or $D^* \to D\gamma$, the latter mode being important in the case of $B_s \to D_s^*$ decays. We show that the angular coefficients in the distributions can be used to scrutinize the role of the form factor parametrization and to pin down deviations from SM. As an example of a NP scenario, we include a tensor operator in the $b \to c$ semileptonic effective Hamiltonian, and discuss how the angular coefficients allow to construct observables sensitive to this structure, also defining ratios useful to test LFU.
1 Introduction

Despite the lack of new physics (NP) signals in direct searches at colliders, there are hints of physics beyond the Standard Model (SM) in a few anomalies in the flavour sector, with observables in tension with the SM predictions. In particular, tree-level semileptonic $B$ decays unexpectedly point to violation of lepton flavour universality (LFU), since the measured ratios $R(D^{(*)}) = \frac{\mathcal{B}(B \to D^{(*)}\tau\bar{\nu}_\tau)}{\mathcal{B}(B \to D^{(*)}\ell\bar{\nu}_\ell)}$ reveal an anomalous deviation of semitauonic $B$ modes with respect to $\mu$ and $e$ ones. The HFLAV averages [1] of BaBar [2,3], Belle [4,6] and LHCb [7] Collaboration measurements,

$$R(D) = 0.403 \pm 0.040 \pm 0.024, \quad R(D^*) = 0.310 \pm 0.015 \pm 0.008,$$

compared to the first SM predictions $R(D) = 0.296 \pm 0.016$, $R(D^*) = 0.252 \pm 0.003$ [8] and to the updated one $R(D) = 0.300 \pm 0.008$ [9], show a deviation at a global 3.9$\sigma$ level. In the case of $R(D^*)$, the recent Belle result $R(D^*) = 0.270 \pm 0.035$ (stat) $^{+0.028}_{-0.025}$ (syst) [10] reduces the average in (1). The LHCb measurement $R(J/\psi) = \frac{\mathcal{B}(B_c^+ \to J/\psi \tau^+\nu_\tau)}{\mathcal{B}(B_c^+ \to J/\psi \mu^+\nu_\mu)} = 0.71 \pm 0.17$ (stat)$\pm 0.18$ (syst) [11] is also slightly above the range of existing predictions within SM, but for this mode the theoretical error still needs to be precisely assessed [12]. In SM the couplings of charged leptons to gauge bosons are lepton-flavour independent, and LFU is only broken by the Yukawa interaction, hence, evidences of LFU violation in $b$-hadron semileptonic modes signal physics beyond SM.

There are other puzzles affecting semileptonic heavy meson decays, in particular the tension between the determinations of the CKM matrix elements $|V_{cb}|$ and $|V_{ub}|$ from inclusive and exclusive $B$ modes. Focusing on $|V_{cb}|$, precise determinations are obtained from the exclusive $B \to D^*\ell\bar{\nu}_\ell$ and $B \to D\ell\bar{\nu}_\ell$ decays and from the inclusive $B \to X_c \ell\bar{\nu}_\ell$ mode. In $B \to D^*$ the procedure to determine $|V_{cb}|$ is based on the extrapolation of the dilepton invariant mass spectrum up to the maximum value, using as an input hadronic form factors at this kinematical point computed by lattice QCD. The FLAG averages $|V_{cb}|_{excl}^{D^*} = (39.27 \pm 0.56_{\text{stat}} \pm 0.49_{\text{exp}}) \times 10^{-3}$ and $|V_{cb}|_{incl}^{D^*} = (40.85 \pm 0.98) \times 10^{-3}$ [9] have to be compared to $|V_{cb}|_{incl} = (42.46 \pm 0.88) \times 10^{-3}$ obtained in the kinetic scheme [11].

Considering the two sets of anomalies, the past viewpoint was to invoke NP in the ratios $R(D^{(*)})$, and to attribute the inclusive/exclusive tensions in $|V_{cb}|$ and $|V_{ub}|$ to some underlying assumptions, namely the uncertainty in the quark-hadron duality ansatz adopted for the inclusive measurement. Recent studies for $|V_{cb}|$ have focused, instead, on the errors involved in the analysis of the $B \to D^*\ell\bar{\nu}_\ell$ spectrum at the maximum dilepton invariant mass. The procedure usually adopted in the experimental determinations was based on the Caprini-Lellouch-Neubert (CLN) parametrization of the $B \to D^*$ form factors [13], which uses heavy quark (HQ) symmetry relations with the inclusion of radiative and $1/m_Q$ corrections. On the other hand, the deconvoluted fully differential $B^0 \to D^{(*)+}\ell^-\bar{\nu}_\ell$ decay distribution measured by Belle [14] has been fitted adopting the Boyd-Grinstein-Lebed (BGL) parametrization of the form factors [15,17], resulting in a value for $|V_{cb}|$ compatible with the inclusive one [18,20]. Although the outcome refers to a single data set, the question has been raised if the form factor parametrization provides a solution of the $|V_{cb}|$ anomaly.

The idea that a common explanation could be found for the $R(D^{(*)})$ and $|V_{cb}|$ anomalies,
invoking NP, has also been put forward \cite{21}. As an example, adding a tensor operator to the SM effective $b \to c$ semileptonic Hamiltonian, weighted by a complex lepton-flavour dependent parameter $\epsilon_T^\ell$, it has been shown that a difference of $\epsilon_T^\ell$ with respect to $\epsilon_T^{\mu,e}$ could account for the $R(D^{(*)})$ anomaly, considering $\epsilon_T^\mu = \epsilon_T^e = 0$ \cite{22}. Relaxing the latter assumption, inclusive and exclusive $B$ semileptonic decays with $\mu$ and $e$ have been scrutinized showing that, for $\epsilon_T^\mu \neq 0$ and $\epsilon_T^e \neq 0$, it is also possible to pin down a region in the parameter space ($Re(\epsilon_T^\mu), Im(\epsilon_T^\mu), |V_{cb}|$) where the inclusive $B^- \to X^0_\ell \ell^\mu \nu_\ell$ and exclusive $B^- \to D^{(*)0} \ell^- \nu_\ell$ branching fractions, as well as the spectrum $d\mathcal{B}(B^- \to D^{(*)0} \ell^- \nu_\ell)/dq^2$ close to maximum $q^2$ are recovered \cite{21}.

Here we reconsider the two issues, the role of the form factor parametrization and the possibility of non SM effects. We focus on $B \to D^* \ell \bar{\nu}_\ell$ in the case of both light $\mu, e$ and heavy $\tau$ lepton, with the $D^*$ decaying to $D\pi$ or $D\gamma$. The latter mode is particularly relevant for $B_s \to D_s^*$ transitions. We express the fully differential decay rate in $B \to D^*(D\pi)\ell^-\bar{\nu}_\ell$ and $\bar{B} \to D^*(D\gamma)\ell^-\bar{\nu}_\ell$ in terms of angular coefficient functions, and show how the analysis of the two modes may shed light on the form factor parametrization. We also reconsider the NP model in \cite{21,22} and study the modified angular coefficients, proposing a set of sensitive observables. Other investigations focusing on the angular distributions have been carried out in \cite{23,32}. A tensor structure appears, for example, in the effective Hamiltonian of leptoquark models, in variants of which it is possible to accommodate a few $B$ anomalies \cite{33,35}. Attempts for a combined explanation of the anomalies in NP frameworks can be found in \cite{36}, while the role of ew corrections has been studied in \cite{37}.

This is the plan of the paper. After having set the stage for the calculation, in section \section{2} we discuss the fully angular distributions and the properties of the angular coefficient functions. Results in SM are presented in section \section{3} where the effects of the form factor parametrization, in particular CLN vs BGL, are investigated. In section \section{4} we compare the angular coefficients in SM and in the NP model with the tensor operator. A set of observables is considered in section \section{5} and ratios useful to test LFU are scrutinized. Our conclusions are presented in the last section.

\section{2 Setting the stage}

We consider $\bar{B}(p_B) \to D^*(p_{D^*}, \epsilon)\ell^- (k_1)\bar{\nu}_\ell (k_2)$, where $\bar{B} \to D^*$ denotes either $\bar{B}^0 \to D^{*+}$ or $\bar{B}^- \to D^{*0}$, followed by the decay $D^*(p_{D^*}, \epsilon) \to (p_D)F(p_F)$ with $F = \pi$ or $\gamma$. For the kinematics we adopt the convention for angles and momenta as in figure \figref{fig:fig1} with lepton-pair momentum $q = k_1 + k_2 = p_B - p_{D^*}$. In the derivation, we extend to NP the procedure in \cite{38,39} for $F = \pi$, considering also the case $F = \gamma$.

The amplitude of the process

$$A_{\text{TOT}}(\bar{B} \to D^*(\to DF)\ell^- \bar{\nu}_\ell) = A(\bar{B} \to D^*\ell^- \bar{\nu}_\ell) \left( \frac{i}{p_{D^*}^2 - m_{D^*}^2 + i m_{D^*} \Gamma(D^*)} \right) A(D^* \to DF)$$

involves three factors. To describe $\bar{B} \to D^* \ell^- \bar{\nu}_\ell$ we focus on the effective Hamiltonian

$$H_{\text{eff}} = \frac{G_F}{\sqrt{2}} V_{cb} \left[ \bar{c} \gamma_\mu (1 - \gamma_5) b \bar{\ell} \gamma^\mu (1 - \gamma_5) \nu_\ell + \epsilon_T^\ell \bar{c} \sigma_{\mu\nu} (1 - \gamma_5) b \bar{\ell} \sigma^{\mu\nu} (1 - \gamma_5) \nu_\ell \right] + h.c. ,$$
consisting in the Standard Model term and in a new physics term with a tensor operator weighted by a lepton-flavour dependent complex parameter $\epsilon^\ell_T$. This allows to write

$$A(\bar{B} \to D^*\ell^-\bar{\nu}_\ell) = \frac{G_F}{\sqrt{2}} V_{cb} \left[ H^{SM}_\mu L^{SM \mu} + \epsilon^\ell_T H^{NP}_{\mu\nu} L^{NP \mu\nu} \right]$$

(4)

in terms of the quark current matrix elements

$$H^{SM}_\mu(m) = \langle D^*(p_{D^*},\epsilon(m))|\bar{c}\gamma_\mu(1 - \gamma_5)b|\bar{B}(p_B)\rangle = \epsilon^\alpha(m) T^{SM}_{\mu\alpha}$$

(5)

$$H^{NP}_{\mu\nu}(m) = \langle D^*(p_{D^*},\epsilon(m))|\bar{c}\sigma_{\mu\nu}(1 - \gamma_5)b|\bar{B}(p_B)\rangle = \epsilon^\alpha(m) T^{NP}_{\mu\nu\alpha}$$

(6)

and of the lepton currents

$$L^{SM \mu} = \bar{\ell}\gamma^\mu(1 - \gamma_5)\nu_\ell$$

(7)

$$L^{NP \mu\nu} = \bar{\ell}\sigma^{\mu\nu}(1 - \gamma_5)\nu_\ell.$$  

(8)

In $[5]$ and $[6]$ the index $m$ of the $D^*$ polarization vector $\epsilon$ runs over $m = \pm, 0$. In the lepton-pair rest-frame (LRF), with the $D^*$ three-momentum along the positive $z$-axis, one has:

$$p_B = (E_B, 0, 0, |\vec{p}_{D^*}|) , \quad p_{D^*} = (E_{D^*}, 0, 0, |\vec{p}_{D^*}|) , \quad q = (\sqrt{q^2}, 0, 0) ,$$

$$\epsilon_\pm = \frac{1}{\sqrt{2}} (0, 1, \mp i, 0) , \quad \epsilon_0 = \frac{1}{m_{D^*}} (|\vec{p}_{D^*}|, 0, 0, E_{D^*}) ,$$

(9)

with $|\vec{p}_{D^*}| = \lambda^{1/2}(m_B^2, m_{D^*}^2, q^2)$ and $E_{D^*} = \frac{m_B^2 - m_{D^*}^2 - q^2}{2\sqrt{q^2}}$, $\lambda$ being the triangular function. The orientation of the lepton momenta is fixed by the angles $\theta$ and $\phi$ as in figure $[1]$ so that

$$k_1 = (k_1^0, |\vec{k}_1| \sin \theta \cos \phi, |\vec{k}_1| \sin \theta \sin \phi, |\vec{k}_1| \cos \theta)$$

$$k_2 = (k_2^0, -|\vec{k}_1| \sin \theta \cos \phi, -|\vec{k}_1| \sin \theta \sin \phi, -|\vec{k}_1| \cos \theta).$$

(10)

In terms of the $D^*$ polarization indices one can write

$$|A(\bar{B} \to D^*\ell^-\bar{\nu}_\ell)(m,n)|^2 = \frac{G_F^2}{2} |V_{cb}|^2 \left[ H^{SM}(m,n) + H^{NP}(m,n) + H^{INT}(m,n) \right] ,$$

(11)

where

$$H^{SM}(m,n) = H^{SM}_\mu(m)(H^{SM})^\dagger_{\mu'}(n) L^{SM \mu\mu'},$$

(12)

$$H^{NP}(m,n) = |\epsilon_T|^2 \left[ H^{NP}_\mu(m)(H^{NP})^\dagger_{\mu'}(n) L^{NP \mu\mu'} \right],$$

(13)

$$H^{INT}(m,n) = \epsilon_T H^{SM}_\mu(m)(H^{NP})^\dagger_{\mu'}(n) L^{INT \mu\mu'} + \epsilon^\ell_T H^{NP}_\mu(m)(H^{SM})^\dagger_{\mu'}(n) L^{INT \mu\mu'},$$

(14)

$^1$We only consider the tensor operator, although other operators could be produced by ew renormalization-group evolution $[40]$. 

in terms of the quantities in (5), (6) and
\[ L^{SM, \mu \nu'} = L^{SM, \mu} (L^{SM, \mu'})^\dagger, \]
\[ L^{NP, \mu \nu \nu'} = L^{NP, \mu \nu} (L^{NP, \mu \nu'})^\dagger, \]
\[ L_{1}^{INT, \mu \nu \nu'} = L^{SM, \mu} (L^{NP, \mu \nu'})^\dagger \]
\[ L_{2}^{INT, \mu \nu \nu'} = L^{NP, \mu \nu} (L^{SM, \mu'}). \]  

As for the $D^{*}$ propagator, the narrow-width approximation can be used for the state produced nearly on-shell [41],
\[ \frac{1}{(p_{D*}^2 - m_{D*}^2) + m_{D*}^2 \Gamma(D^*)^2} = \frac{\pi}{m_{D} \Gamma(D^{*})} \delta(p_{D*}^2 - m_{D*}^2). \]  

On the other hand, the $D^{*} \rightarrow DF$ amplitude can be written as
\[ \mathcal{A}(D^{*} \rightarrow DF) = g_{D^{*}DF} (\epsilon \cdot Q) \]  

where $Q = p_{D}$ for $F = \pi$, and $Q_{\beta} = i \epsilon_{\alpha \beta \sigma \tau} \eta^{\alpha} p_{D}^{\sigma} p_{D}^{\tau}$ for $F = \gamma$, with $\eta$ the photon polarization vector. One can get rid of the coupling $g_{D^{*}DF}$ considering
\[ \Gamma(D^{*} \rightarrow DF) = g_{D^{*}DF}^2 \frac{|\vec{p}_{D}|}{24\pi m_{D}^4} \left[ (p_{D}^2 \cdot Q)^2 - Q^2 m_{D*}^2 \right], \]  

with $|\vec{p}_{D}| = \frac{\lambda^{1/2} (m_{D*}^2, m_{D}^2, m_{F}^2)}{2m_{D*}}$ the $D$ three-momentum in the $D^{*}$ rest frame ($D^{*}$RF). In particular, one has $[(p_{D}^2 \cdot Q)^2 - Q^2 m_{D*}^2] = m_{D}^2 |\vec{p}_{D}|^2$ for $F = \pi$ and $2m_{D}^4 |\vec{p}_{D}|^2$ for $F = \gamma$. 

Figure 1: Kinematics of $\bar{B} \rightarrow D^{*}(\rightarrow DF)\ell^{-}\bar{\nu}_{\ell}$
Specifying the $D^*$ polarization indices, one can write

$$|\mathcal{A}(D^* \to DF)|^2(m, n) = \Gamma(D^* \to DF) \left[ \frac{24\pi m_{D^*}^2}{|p_D|^3} \right] F_F(m, n),$$

(19)

with

$$F_F(m, n) = c_F [\epsilon(m) \cdot Q] [\epsilon(n) \cdot Q]^\dagger$$

(20)

and the constant $c_\pi = 1$ for $F = \pi$, and $c_\gamma = 1/(2m_{D^*}^2)$ for $F = \gamma$. The $(3 \times 3) F_F(m, n)$ matrices in (20) involve the angle $\theta_V$:

$$F_\pi = \frac{|p_D|^2}{2} \begin{pmatrix}
\sin^2 \theta_V & \sin^2 \theta_V & \frac{1}{\sqrt{2}} \sin 2\theta_V \\
\sin^2 \theta_V & \sin^2 \theta_V & \frac{1}{\sqrt{2}} \sin 2\theta_V \\
\frac{1}{\sqrt{2}} \sin 2\theta_V & \frac{1}{\sqrt{2}} \sin 2\theta_V & 2\cos^2 \theta_V
\end{pmatrix}$$

(21)

$$F_\gamma = \frac{|p_D|^2}{4} \begin{pmatrix}
\frac{3+\cos 2\theta_V}{2} & -\sin^2 \theta_V & -\frac{1}{\sqrt{2}} \sin 2\theta_V \\
-\sin^2 \theta_V & \frac{3+\cos 2\theta_V}{2} & -\frac{1}{\sqrt{2}} \sin 2\theta_V \\
-\frac{1}{\sqrt{2}} \sin 2\theta_V & -\frac{1}{\sqrt{2}} \sin 2\theta_V & 2\sin^2 \theta_V
\end{pmatrix}.$$  

(22)

Collecting the various terms in Eq. (2) we obtain

$$|\mathcal{A}_{TOT}(B \to D^*(\to DF)(\ell^- \nu_\ell)|^2 = G^2_F|V_{cb}|^2 \frac{12\pi^2 m_{D^*}^2}{|p_D|^3} \mathcal{B}(D^* \to DF) \delta(p_{D^*}^2 - m_{D^*}^2)$$

$$\times \{ Tr \left[ (\mathcal{H}^{SM})^T \cdot F_F \right] + Tr \left[ (\mathcal{H}^{NP})^T \cdot F_F \right] + Tr \left[ (\mathcal{H}^{INT})^T \cdot F_F \right] \},$$

(23)

where the trace is carried out over the indices $(m, n)$, ordered as $(1, 2, 3) = (+, -, 0)$, and $T$ meaning the transpose. The expression of the fully differential decay distribution can be worked out considering the four-body phase-space recalled in appendix A:

$$\frac{d^4\Gamma(B \to D^*(\to DF)(\ell^- \nu_\ell)}}{dq^2 \, d\cos \theta \, d\phi \, d\cos \theta_V} = \frac{3G^2_F|V_{cb}|^2 \mathcal{B}(D^* \to DF) |p_D|^2 |B_{RF}|}{128(2\pi)^4 m_B^2} \left( 1 - \frac{m_P^2}{q^2} \right)$$

$$\times \{ Tr \left[ (\mathcal{H}^{SM})^T \cdot F_F \right] + Tr \left[ (\mathcal{H}^{NP})^T \cdot F_F \right] + Tr \left[ (\mathcal{H}^{INT})^T \cdot F_F \right] \}.$$  

(24)

The hadronic matrix elements (5),(6) can be parametrized in terms of form factors. We use the definition

$$\langle D^*(p_{D^*}, \epsilon) | \bar{c} \gamma_\mu (1-\gamma_5) b | B(p_B) \rangle = -\frac{2V(q^2)}{m_B + m_{D^*}} i\epsilon_{\mu\alpha\beta\gamma} \epsilon^{*\mu} p_B^\alpha p_{D^*}^\beta$$

$$- \left\{ (m_B + m_{D^*}) \left[ \epsilon^*_\mu - \frac{(\epsilon^* \cdot q)}{q^2} q_\mu \right] A_1(q^2) \right\}$$

$$- \frac{(\epsilon^* \cdot q)}{m_B + m_{D^*}} \left[ (p_B + p_{D^*})_\mu - \frac{m_B^2 - m_{D^*}^2}{q^2} q_\mu \right] A_2(q^2)$$

$$+ (\epsilon^* \cdot q) \frac{2m_{D^*}}{q^2} q_\mu A_0(q^2)$$

(25)
with the condition \( A_0(0) = \frac{m_B + m_{D^*}}{2m_{D^*}} A_1(0) - \frac{m_B - m_{D^*}}{2m_{D^*}} A_2(0) \) and

\[
\langle D^*(p_{D^*}, \epsilon) | \bar{c} \sigma_{\mu \nu} (1 - \gamma_5) b | \bar{B}(p_B) \rangle = T_0(q^2) \frac{\epsilon^* \cdot q}{(m_B + m_{D^*})^2} \epsilon_{\mu \nu \alpha \beta} p_B^\alpha p_{D^*}^\beta + T_1(q^2) \epsilon_{\mu \alpha \beta} p_B^\alpha \epsilon^{* \beta} + T_2(q^2) \epsilon_{\mu \alpha \beta} p_{D^*}^\alpha \epsilon^{* \beta} + i \left[ T_3(q^2) (\epsilon_{\mu} p_{B \nu} - \epsilon_{\nu} p_{B \mu}) + T_4(q^2) (\epsilon_{\mu} p_{D^* \nu} - \epsilon_{\nu} p_{D^* \mu}) + T_5(q^2) \frac{\epsilon^* \cdot q}{(m_B + m_{D^*})^2} (p_{B \mu} p_{D^* \nu} - p_{B \nu} p_{D^* \mu}) \right].
\]

We also define \( \bar{T}_0 = T_0 - T_5 \), \( \bar{T}_1 = T_1 + T_3 \) and \( \bar{T}_2 = T_2 + T_4 \). In appendix \( \text{B} \) we describe other matrix element parametrizations. In SM one can relate the helicity amplitudes for the \( D^* \) polarization states to the polarizations of the virtual \( W(q, \epsilon) \). In the LRF one writes

\[
\bar{\epsilon}_\pm = \frac{1}{\sqrt{2}} (0, 1, \pm i, 0), \quad \bar{\epsilon}_0 = (0, 0, 0, 1), \quad \bar{\epsilon}_t = (1, 0, 0, 0).
\]

This allows to define the amplitudes

\[
H_m = \bar{\epsilon}_m^* \epsilon_{m \alpha} T_{\mu \alpha} \quad (m = 0, \pm)
\]

\[
H_t = \bar{\epsilon}_t^* \epsilon_0^* T_{\mu \alpha} \quad (m = t)
\]

which can be expressed in terms of the form factors in \( [25] \):

\[
H_0 = \frac{(m_B + m_{D^*})^2 (m_B^2 - m_{D^*}^2 - q^2) A_1(q^2) - \lambda (m_B^2, m_{D^*}^2, q^2) A_2(q^2)}{2m_{D^*} (m_B + m_{D^*}) \sqrt{q^2}}
\]

\[
H_\pm = \frac{(m_B + m_{D^*})^2 A_1(q^2) \mp \sqrt{\lambda (m_B^2, m_{D^*}^2, q^2)} V(q^2)}{m_B + m_{D^*}}
\]

\[
H_t = -\frac{\sqrt{\lambda (m_B^2, m_{D^*}^2, q^2)}}{\sqrt{q^2}} A_0(q^2)
\]

All the entries in \( \mathcal{H}^{SM}(m, n) \) can be written in terms of \( H_\pm, H_0 \) and \( H_t \).

## 3 Angular decomposition of the fully differential decay distribution

The fully differential decay distribution for the chain process \( \bar{B} \to D^* \to DF \ell^- \bar{\nu}_\ell \), with \( F = \pi \) and \( F = \gamma \), can be worked out in terms of the angles in fig. \( \text{I} \). For \( F = \pi \) it can be
expressed as

\[
\frac{d^4 \Gamma(\bar{B} \to D^* (\to D\pi)e^-(\bar{\nu}_e))}{dq^2 \, d \cos \theta \, d\phi \, d \cos \theta_V} = \mathcal{N}_F |\vec{p}_{D^*}| \left(1 - \frac{m_t^2}{q^2}\right)^2 \left\{ I_{1s}^\pi \sin^2 \theta_V + I_{1c}^\pi (3 + \cos 2\theta_V) \right. \\
+ \left. (I_{2s}^\pi \sin^2 \theta_V + I_{2c}^\pi (3 + \cos 2\theta_V)) \cos 2\theta \right.
\]

\[
+ I_3^\pi \sin^2 \theta_V \sin^2 \theta \cos 2\phi + I_4^\pi \sin 2\theta_V \sin 2\theta \cos \phi
\]

\[
+ I_5^\pi \sin 2\theta_V \sin \theta \cos \phi + \left( I_{6s}^\pi \sin^2 \theta_V + I_{6c}^\pi \cos^2 \theta_V \right) \cos \theta
\]

\[
+ I_7^\pi \sin 2\theta_V \sin \theta \sin \phi \right\}
\]

with \( \mathcal{N}_F = \frac{3G_F^2 |V_{cb}|^2 B(D^* \to DF)}{128(2\pi)^4 m_B^2} \). For \( F = \gamma \) we adopt the decomposition

\[
\frac{d^4 \Gamma(\bar{B} \to D^* (\to D\gamma)e^-(\bar{\nu}_e))}{dq^2 \, d \cos \theta \, d\phi \, d \cos \theta_V} = \mathcal{N}_F |\vec{p}_{D^*}| \left(1 - \frac{m_t^2}{q^2}\right)^2 \left\{ I_{1s}^\gamma \sin^2 \theta_V + I_{1c}^\gamma (3 + \cos 2\theta_V) \right. \\
+ \left. (I_{2s}^\gamma \sin^2 \theta_V + I_{2c}^\gamma (3 + \cos 2\theta_V)) \cos 2\theta \right.
\]

\[
+ I_3^\gamma \sin^2 \theta_V \sin^2 \theta \cos 2\phi + I_4^\gamma \sin 2\theta_V \sin 2\theta \cos \phi
\]

\[
+ I_5^\gamma \sin 2\theta_V \sin \theta \cos \phi + \left( I_{6s}^\gamma \sin^2 \theta_V + I_{6c}^\gamma (3 + \cos 2\theta_V) \right) \cos \theta
\]

\[
+ I_7^\gamma \sin 2\theta_V \sin \theta \sin \phi \right\}
\]

In the Standard Model the coefficients of the angular terms are related to the helicity amplitudes \( \{I_n\} \):

\[
I_{1s}^\pi = \frac{1}{2} (H_+^2 + H_-^2)(m_t^2 + 3q^2) \, , \quad I_{1c}^\pi = 2(2m_t^2 H_+^2 + H_0^2(m_t^2 + q^2)) \, ,
\]

\[
I_{2s}^\pi = \frac{1}{2} (H_+^2 + H_-^2)(q^2 - m_t^2) \, , \quad I_{2c}^\pi = 2H_0^2(m_t^2 - q^2) \, ,
\]

\[
I_3^\pi = 2H_+H_-m_t^2 - q^2 \, , \quad I_4^\pi = H_0(H_+ + H_-)(m_t^2 - q^2) \, ,
\]

\[
I_5^\pi = -2(H_+ + H_-)H_t m_t^2 - 2H_0(H_+ - H_-)q^2 \, ,
\]

\[
I_{6s}^\pi = 2(H_+^2 - H_-^2)q^2 \, , \quad I_{6c}^\pi = -8H_0 H_t m_t^2 \, ,
\]

\[
I_7^\pi = 0 \, ,
\]

\footnotesize

\footnotesize

2In principle, other two structures \( I_8 \sin 2\theta_V \sin 2\theta \sin \phi + I_9 \sin^2 \theta_V \sin^2 \theta \sin 2\phi \) could be present in these decompositions. We do not include them, since they are absent in SM and in the NP model considered here.
and
\[
I_{1s} = 2m_{\ell}^2H_t^2 + H_0^2(m_{\ell}^2 + q^2), \quad I_{1c} = \frac{1}{8}(H_+^2 + H_-^2)(m_{\ell}^2 + 3q^2),
\]
\[
I_{2s} = H_0^2(m_{\ell}^2 - q^2), \quad I_{2c} = \frac{1}{8}(H_+^2 + H_-^2)(q^2 - m_{\ell}^2),
\]
\[
I_3 = -H_+H_- (m_{\ell}^2 - q^2), \quad I_4 = -\frac{1}{2}H_0(H_+ + H_-)(m_{\ell}^2 - q^2),
\]
\[
I_5 = (H_+ + H_-)H_t m_{\ell}^2 + H_0(H_+ - H_-)q^2,
\]
\[
I_6 = -4H_0H_t m_{\ell}^2, \quad I_{6c} = \frac{1}{2}(H_+^2 - H_-^2)q^2,
\]
\[
I_7 = 0.
\]

Hence, the coefficients in \(D\pi\) and \(D\gamma\) angular distributions obey the relations, for all \(q^2\),
\[
\frac{I_{1s}}{4I_{1s}} = \frac{I_{1c}}{2I_{1s}} = \frac{I_{2s}}{4I_{2c}} = \frac{I_{2c}}{2I_{2s}} = \frac{I_{6s}}{2I_{6c}} = \frac{I_{6c}}{4I_{6s}} = -\frac{I_3}{2I_3} = -\frac{I_4}{2I_4} = -\frac{I_5}{2I_5} = 1.
\] (34)

Integrated distributions are written in terms of the angular coefficients. In particular, the \(q^2\) distributions read:
\[
\frac{d\Gamma}{dq^2}|_{F=\pi} = N_\pi|\vec{p}_{D^*}| \left(1 - \frac{m_{\ell}^2}{q^2}\right)^2 \frac{8}{9} \pi (6I_{1s}^\pi + 3I_{1c}^\pi - 2I_{2s}^\pi - I_{2c}^\pi),
\] (35)
\[
\frac{d\Gamma}{dq^2}|_{F=\gamma} = N_\gamma|\vec{p}_{D^*}| \left(1 - \frac{m_{\ell}^2}{q^2}\right)^2 \frac{16}{9} \pi (3I_{1s}^\gamma + 12I_{1c}^\gamma - I_{2s}^\gamma - 4I_{2c}^\gamma).
\] (36)

The angular coefficients encode information on the form factors, and vice-versa. Their fit from the experimental fully differential decay distribution allows to reconstruct the form factors, with a possible comparison of measurements to theory determinations. Considering the \(D\pi\) mode one has
\[
A_1(q^2) = \frac{1}{4(m_B + m_{D^*})} \left\{ \sqrt{\frac{4I_{1s}^\pi}{m_{\ell}^2 + 3q^2} - \frac{I_{6s}^\pi}{q^2}} + \sqrt{\frac{4I_{1s}^\pi}{m_{\ell}^2 + 3q^2} + \frac{I_{6s}^\pi}{q^2}} \right\},
\]
\[
A_2(q^2) = \frac{(m_B + m_{D^*})}{4\lambda (m_B, m_{D^*}, q^2)} \left\{ \frac{(m_B^2 - m_{D^*}^2)}{q^2} - q^2 \left[ \sqrt{\frac{4I_{1s}^\pi}{m_{\ell}^2 + 3q^2} - \frac{I_{6s}^\pi}{q^2}} + \sqrt{\frac{4I_{1s}^\pi}{m_{\ell}^2 + 3q^2} + \frac{I_{6s}^\pi}{q^2}} \right] \right\} - 4\sqrt{2m_{D^*}} \sqrt{\frac{-I_{2c}^\pi}{q^2 - m_{\ell}^2}},
\]
\[
V(q^2) = \frac{(m_B + m_{D^*})}{4\lambda^{1/2}(m_B, m_{D^*}^2, q^2)} \left\{ \sqrt{\frac{4I_{1s}^\pi}{m_{\ell}^2 + 3q^2} - \frac{I_{6s}^\pi}{q^2}} - \sqrt{\frac{4I_{1s}^\pi}{m_{\ell}^2 + 3q^2} + \frac{I_{6s}^\pi}{q^2}} \right\},
\] (37)
\[
A_0(q^2) = \frac{1}{2 \lambda^{1/2}(m_B, m_{D^*}^2, q^2)} \sqrt{\frac{(q^2 - m_{\ell}^2)I_{1c}^\pi + (q^2 + m_{\ell}^2)I_{2c}^\pi}{m_{\ell}^2(q^2 - m_{\ell}^2)}}.
\]
Analogously, from the $D\gamma$ mode one has

$$A_1(q^2) = \frac{1}{2(m_B + m_{D^*})} \left\{ \sqrt{\frac{4I_{1c}^\gamma}{m_B^2 + 3q^2}} - \frac{I_{6c}^\gamma}{q^2} + \sqrt{\frac{4I_{1c}^\gamma}{m_{D^*}^2 + 3q^2}} + \frac{I_{6c}^\gamma}{q^2} \right\},$$

$$A_2(q^2) = \frac{(m_B + m_{D^*})}{2\lambda (m_B^2, m_{D^*}^2, q^2)} \left\{ (m_B^2 - m_{D^*}^2 - q^2) \left[ \sqrt{\frac{4I_{1c}^\gamma}{m_B^2 + 3q^2}} - \frac{I_{6c}^\gamma}{q^2} + \sqrt{\frac{4I_{1c}^\gamma}{m_{D^*}^2 + 3q^2}} + \frac{I_{6c}^\gamma}{q^2} \right] 
- 4m_{D^*} \sqrt{q^2 - \frac{I_{2s}^\gamma}{q^2 - m_{D^*}^2}} \right\},$$

$$V(q^2) = \frac{\sqrt{q^2}}{2\sqrt{2}(m_B^2, m_{D^*}^2, q^2)} \left[ (q^2 - m_{D^*}^2) I_{1s}^\gamma + (q^2 + m_B^2) I_{2s}^\gamma \right].$$

(38)

Such relations require precise signs for the angular coefficient functions and for a few of their combinations.

Considering the tensor operator in the effective Hamiltonian $H$, the fully differential decay distribution can still be written as in Eqs. (30), (31), with the coefficients $I_i$ replaced by $I_i + |\epsilon_T|^2 I_i^{NP} + 2 \text{Re}(\epsilon_T) I_i^{INT}$ for $i = 1, \ldots, 6$, and by $I_i + |\epsilon_T|^2 I_i^{NP} + 2 \text{Im}(\epsilon_T) I_i^{INT}$ for $i = 7$. With the definitions

$$H_{+}^{NP} = \frac{1}{2\sqrt{q^2}} \left\{ \left[ m_B^2 - m_{D^*}^2 + \lambda^{1/2}(m_B^2, m_{D^*}^2, q^2) \right] (\tilde{T}_1 + \tilde{T}_2) + q^2 (\tilde{T}_1 - \tilde{T}_2) \right\},$$

$$H_{-}^{NP} = \frac{1}{2\sqrt{q^2}} \left\{ \left[ m_B^2 - m_{D^*}^2 - \lambda^{1/2}(m_B^2, m_{D^*}^2, q^2) \right] (\tilde{T}_1 + \tilde{T}_2) + q^2 (\tilde{T}_1 - \tilde{T}_2) \right\},$$

(39)

$$H_{L}^{NP} = 2 \left\{ \frac{\lambda (m_B^2, m_{D^*}^2, q^2)}{m_{D^*}(m_B + m_{D^*})^2} \tilde{T}_0 + 2m_B^2 + m_{D^*}^2 - q^2 \right\} (\tilde{T}_1 + 4m_{D^*} \tilde{T}_2) \right\},$$

one has:

$$I_{1s}^{NP,\pi} = 2[(H_{+}^{NP})^2 + (H_{-}^{NP})^2](3m_{D^*}^2 + q^2),$$

$$I_{1c}^{NP,\pi} = \frac{1}{8}(q^2 + m_{D^*}^2)(H_{L}^{NP})^2, $$

$$I_{2s}^{NP,\pi} = 2[(H_{+}^{NP})^2 + (H_{-}^{NP})^2](m_{D^*}^2 - q^2),$$

$$I_{2c}^{NP,\pi} = \frac{1}{8}(q^2 - m_{D^*}^2)(H_{L}^{NP})^2, $$

$$I_{3}^{NP,\pi} = 8H_{+}^{NP} H_{-}^{NP} (q^2 - m_{D^*}^2),$$

$$I_{4}^{NP,\pi} = \frac{1}{2}(q^2 - m_{D^*}^2) H_{L}^{NP} [H_{+}^{NP} + H_{-}^{NP}], $$

$$I_{5}^{NP,\pi} = -m_{D^*}^2 H_{L}^{NP} [H_{-}^{NP} - H_{+}^{NP}], $$

$$I_{6s}^{NP,\pi} = 8m_{D^*}^2 (H_{+}^{NP})^2 - (H_{-}^{NP})^2, $$

$$I_{6c}^{NP,\pi} = 0, $$

$$I_{7}^{NP,\pi} = 0, $$

(40)
and

\[ I_{1s}^{NP,\gamma} = \frac{1}{16}(H_L^{NP})^2(q^2 + m_{\ell}^2), \quad I_{1c}^{NP,\gamma} = \frac{1}{2}[(H_+^{NP})^2 + (H_-^{NP})^2](3m_{\ell}^2 + q^2), \]

\[ I_{2s}^{NP,\gamma} = \frac{1}{16}(q^2 - m_{\ell}^2)(H_L^{NP})^2, \quad I_{2c}^{NP,\gamma} = -\frac{1}{2}[(H_+^{NP})^2 + (H_-^{NP})^2](q^2 - m_{\ell}^2), \]

\[ I_3^{NP,\gamma} = -4H_+^{NP}H_-^{NP}(q^2 - m_{\ell}^2), \quad I_4^{NP,\gamma} = -\frac{1}{4}(q^2 - m_{\ell}^2)H_L^{NP}[H_+^{NP} + H_-^{NP}], \]

\[ I_5^{NP,\gamma} = \frac{1}{2}m_{\ell}^2H_L^{NP}[H_+^{NP} - H_-^{NP}], \]

\[ I_6^{NP,\gamma} = 0, \quad I_6^{c,\gamma} = 2m_{\ell}^2[(H_+^{NP})^2 - (H_-^{NP})^2], \]

\[ I_7^{NP,\gamma} = 0. \]

The interference terms are given by

\[ I_{1s}^{INT,\pi} = -4\sqrt{q^2}m_{\ell}(H_+^{NP}H_+ + H_-^{NP}H_-), \quad I_{1c}^{INT,\pi} = -\sqrt{q^2}m_{\ell}H_0H_L^{NP}, \]

\[ I_{2s}^{INT,\pi} = 0, \quad I_{2c}^{INT,\pi} = 0, \]

\[ I_{3}^{INT,\pi} = 0, \quad I_{4}^{INT,\pi} = 0, \]

\[ I_5^{INT,\pi} = \frac{1}{4}\sqrt{q^2}m_{\ell}[H_L^{NP}(H_+ - H_-) + 8H_0(H_+^{NP} - H_-^{NP}) + 8H_t(H_+^{NP} + H_-^{NP})], \]

\[ I_6^{INT,\pi} = -4\sqrt{q^2}m_{\ell}(H_+^{NP}H_+ - H_-^{NP}H_-), \quad I_6^{c,\pi} = \sqrt{q^2}m_{\ell}H_L^{NP}H_t, \]

\[ I_7^{INT,\pi} = \frac{1}{4}\sqrt{q^2}m_{\ell}[H_L^{NP}(H_+ - H_-) - 8H_0(H_+^{NP} + H_-^{NP}) - 8H_t(H_+^{NP} - H_-^{NP})], \]

and

\[ I_{1s}^{INT,\gamma} = -\frac{1}{2}\sqrt{q^2}m_{\ell}H_0H_L^{NP}, \quad I_{1c}^{INT,\gamma} = -m_{\ell}\sqrt{q^2}(H_+^{NP}H_+ + H_-^{NP}H_-), \]

\[ I_{2s}^{INT,\gamma} = 0, \quad I_{2c}^{INT,\gamma} = 0, \]

\[ I_{3}^{INT,\gamma} = 0, \quad I_{4}^{INT,\gamma} = 0, \]

\[ I_5^{INT,\gamma} = \frac{1}{8}m_{\ell}\sqrt{q^2}[-H_L^{NP}(H_+ - H_-) - 8H_0(H_+^{NP} - H_-^{NP}) - 8H_t(H_+^{NP} + H_-^{NP})], \]

\[ I_6^{INT,\gamma} = \frac{1}{2}m_{\ell}\sqrt{q^2}H_tH_L^{NP}, \quad I_6^{c,\gamma} = -\sqrt{q^2}m_{\ell}(H_+^{NP}H_+ - H_-^{NP}H_-), \]

\[ I_7^{INT,\gamma} = \frac{1}{8}\sqrt{q^2}m_{\ell}[-H_L^{NP}(H_+ - H_-) + 8H_0(H_+^{NP} + H_-^{NP}) + 8H_t(H_+^{NP} - H_-^{NP})]. \]

The relations \([34]\) continue to hold.
Understanding the role of the form factor parametrization of the $B \to D^*$ hadronic matrix element is important before the formulation of any strategy to disentangle possible NP effects. The angular distributions can help identifying observables less sensitive to the form factor parametrization, hence more suitable to uncover deviations from SM. Observables displaying a pronounced dependence on such parametrization can help in studying the impact of form factors.

The parametrizations based on the heavy quark limit make use of the relations among the form factors in HQ, in particular the connection, at the leading order in the $1/m_Q$ expansion, of all the form factors to the single Isgur-Wise function $\xi(w)$, with $w = \frac{m_B^2 + m_{D^*}^2 - q^2}{2m_B m_{D^*}}$ the product of $B$ and $D^{(*)}$ four-velocities. $\xi(w)$ is normalized to unity at zero recoil $w = 1$. In the CLN formulation the relations are improved including perturbative $\alpha_s$ and power $1/m_b, 1/m_c$ corrections [13]. In terms of the function $h_{A1}(w)$ defined in appendix B, which coincides with...
Figure 3: Angular coefficients in the fully differential decay distribution Eq. (30) for $\ell = \tau$ in SM. The coefficients in (31) are obtained using (34). Color code as in figure 2.

$A_1(q^2)$ modulo a $w$-dependent coefficient, one can write

$$V(w) = \frac{R_1(w)}{R^*} h_{A_1}(w)$$

$$A_1(w) = \frac{w + 1}{2} R^* h_{A_1}(w)$$

$$A_2(w) = \frac{R_2(w)}{R^*} h_{A_1}(w)$$

$$A_0(w) = \frac{R_0(w)}{R^*} h_{A_1}(w)$$

(44)

with $R^* = \frac{2\sqrt{m_B m_{D^*}}}{m_B + m_{D^*}}$. In this approach, $h_{A_1}(w)$, $R_1(w)$, $R_2(w)$ and $R_0(w)$ are expanded for
$w \to 1$, fixing the series coefficients using dispersive bounds \cite{13}:

$$h_{A_1}(w) = h_{A_1}(1) \left[ 1 - 8\rho^2 z + (53\rho^2 - 15)z^2 - (231\rho^2 - 91)z^3 \right]$$

$$R_1(w) = R_1(1) - 0.12(w - 1) + 0.05(w - 1)^2$$

$$R_2(w) = R_2(1) + 0.11(w - 1) - 0.06(w - 1)^2$$

$$R_0(w) = R_0(1) - 0.11(w - 1) + 0.01(w - 1)^2,$$  \hfill (45)

with the conformal variable $z$ defined as $z = \frac{\sqrt{w + 1} - \sqrt{2}}{\sqrt{w + 1} + \sqrt{2}}$. In the HQ limit the predictions

$$R_{HQ}^1(1) = 1.27,$$  \hfill (46)

$$R_{HQ}^2(1) = 0.80,$$  \hfill (46)

$$R_{HQ}^0(1) = 1.25$$  \hfill (46)

are obtained \cite{13,12}. However, in the experimental analyses making use of this parametrization, not only the slope $\rho^2$, but also the ratios $R_1(1)$ and $R_2(1)$ are fitted parameters, while $h_{A_1}(1)$ is taken from lattice QCD calculations. $R_0(1)$ is involved in the case of $\tau$ lepton, and no experimental result is available. The parameters fitted by Belle Collaboration \cite{14}, that we use in our analysis, are collected in Table 1. We use the last relation in (44), together with the expressions (71) in appendix B to obtain $R_0(1)$.

In the BGL formulation, recalled in appendix B, the form factors are expressed as functions of the conformal variable $z$. After having included outer functions \cite{43} and subtracted the contribution of $b\bar{c}$ states, the form factors are expressed as power series of $z$, with the coefficients determined by a fit to the experimental data \cite{15,17}. The number of parameters for each form factor is larger than in CLN; on the other hand, no information from the HQ limit is used. In our analysis we use the parameters in \cite{18}, obtained fitting the same data set in \cite{14}, in the case where input from light-cone QCD sum rules is included. In the absence of results from the fits, also in this case we use the HQ relations to obtain $R_0$, as in \cite{44}.

A point emphasized in \cite{18,19,44} is that, although the Belle data in \cite{14} can be well reproduced using both parametrizations, the high $q^2$ bins are better described by BGL, with a value of $|V_{cb}|$ larger than using CLN and closer to the inclusive $|V_{cb}|$ determination. In principle, the angular coefficient functions inferred from the fully differential distribution can be used to reconstruct the form factors. In particular, for the ratios $R_1(w)$ and $R_2(w)$ one

| $|V_{cb}| \times 10^3$ | $\rho^2$ | $R_1(1)$ | $R_2(1)$ |
|-----------------|--------|--------|--------|
| $37.4 \pm 1.3$  | $1.03 \pm 0.13$ | $1.38 \pm 0.07$ | $0.87 \pm 0.10$ |

Table 1: CLN parameters fitted by Belle Collaboration \cite{14}. 

5 Angular coefficient functions in the NP model

In the case of the effective Hamiltonian with the tensor operator the angular coefficient functions are modified. To discuss the changes with respect to SM we need to fix a range for the couplings $\epsilon_T^\mu$ and $\epsilon_T^\tau$. In \cite{22} $\epsilon_T^\mu$ was constrained by $R(D)$ and $R(D^*)$, assuming $\epsilon_T^\mu = \epsilon_T^\tau = 0$. In \cite{23} the latter assumption was relaxed, $\epsilon_T^\mu \neq 0$ and $\epsilon_T^\tau \neq 0$, to reproduce $B \to X_c \ell^- \bar{\nu}_\ell$ and

\begin{align*}
R_1(w) &= \frac{8q^2 m_B m_D^\ell (1 + w)}{(m^2 + 3q^2)\lambda^{1/2}(m_B^2, m_D^2, q^2)} I_{6s}^\pi \left[ \sqrt{(I_{1s}^\pi)^2 - \left( \frac{m^2 + 3q^2}{q^2} \right)^2 \left( \frac{(I_{6s}^\pi)^2}{16} - I_{1s}^\pi \right)} \right], \quad (47) \\
R_2(w) &= \frac{2m_B m_D^\ell (1 + w)}{\lambda(m_B^2, m_D^2, q^2)} \left[ (m_B^2 - q^2 - m_D^2) + 2\sqrt{2m_D^\ell q^2} \right] - \frac{q^2}{q^2 - m_t^2} I_{1s}^\pi \left[ \sqrt{\frac{4I_{1s}^\pi}{m_t^2 + 3q^2} - \frac{I_{6s}^\pi}{q^2}} - \sqrt{\frac{4I_{1s}^\pi}{m_t^2 + 3q^2} + \frac{I_{6s}^\pi}{q^2}} \right]. \quad (48)
\end{align*}

This is interesting, since a difference between the CLN and BGL parametrizations emerges in these ratios \cite{18,44,45}.

We now investigate the angular coefficient functions obtained with CLN and BGL, using their respective set of parameters. The results are collected in figure 2. We use as an input the lattice QCD value $h_{A_1}(1) = 0.906 \pm 0.013$ \cite{46} times the EW correction factor $\eta_W = 1.0066$ \cite{47,48}. We also show the results obtained in the HQ limit using Eq. (46).

The functions $I_{1s}^\pi, I_{2s}^\pi, I_3^\pi, I_4^\pi$ and $I_{1c}^\pi, I_{2c}^\pi, I_3^\pi, I_4^\pi$ are largely insensitive to the form factor parametrization. On the contrary, $I_{1c}^\pi, I_{2c}^\pi, I_6^\pi$, and $I_{1s}^\pi, I_{2s}^\pi, I_{6s}^\pi$ are more dependent. The coefficients $I_{6s}^\pi, I_{6s}^\ell$ are proportional to the lepton mass, hence they are small compared to the others for $\ell = \mu$. The indication is that the first set of coefficients is more suitable to pin down deviations from SM. In particular, $I_T^\pi(\gamma)$ vanishes in SM, therefore it is able to signal a NP effect: indeed, in the model with the tensor operator $\text{Im}(\epsilon_T^\pi)$ can be non-vanishing, as well as $I_T^\pi(\gamma)$.

The second set of angular coefficient functions can be used to better evaluate the form factor parametrization. The results in BGL display larger uncertainties, and are systematically larger (smaller) than in CLN in $I_{2c}^\pi, I_{6s}^\pi (I_{1c}^\pi, I_5^\pi)$. An overlap region spanned by the two parametrizations always exists, and the HQ result is closer to the CLN outcome, sometimes at the limits. An analogous trend is found for the $\ell = \tau$ mode, in the angular coefficient functions displayed in figure 3. Comparing $I_{1c}^\pi$ and $I_{2c}^\pi$ for $\ell = \mu$ and $\tau$, one finds that the uncertainties are smaller in the case of the heavier lepton.

The complementarity of the modes with $D^*$ decaying to $D\pi$ or to $D\gamma$ emerges from fig. 4 and 5 obtained using the CLN parametrization. For $F = \pi$ the events are mainly at the limits of the $\cos \theta_{V}$ region, as shown both by the density plots in figure 4 and by the projections in fig. 5. In the case of the photon, the most populated region is for $\cos \theta_{V} \simeq 0$. This should be taken into account in the analysis of $B_s \to D_{s}^{(*)} \ell^- \bar{\nu}_\ell$, where the final state is dominated by the $D_{s}\gamma$ mode.
5 Angular coefficient functions in the NP model

Figure 4: SM scatter plots of the double differential distributions in $w$ and $\cos \theta_V$, with $\tilde{B} = B/B(D^* \rightarrow DF)$, using the CLN parametrization. The upper and lower plots refer to $\ell = \mu$ and $\ell = \tau$ modes, respectively, the left and right column to $F = \pi$ and $F = \gamma$.

$\tilde{B} \rightarrow D^{(s)} \ell \bar{\nu}_\ell$ data in a common range of $|V_{cb}|$. We now consider these constraints, but since the ranges for $e^\mu_T$ and $e^\tau_T$ turn out to be almost coincident, we only distinguish $e^\mu_T$ and $e^\tau_T$. We adopt the CLN parametrization, employing the HQ relations to determine the form factors $T_i$ in (26), since the BGL parametrization for such functions has not been developed.

We use the range of values of $e^\mu_T$ selected in [21], restricted to reproduce $|V_{cb}|$ obtained by the Belle’s fit in Table 1 (within 2$\sigma$). In this range we compute $R(D)$ and $R(D^*)$ using the averages in Eq. (1) at 1$\sigma$ as constraints. For $R(D)$ we use lattice QCD form factors [49]. The obtained ranges for $e^\mu_T$ and $e^\tau_T$ are displayed in figure 6. The regions can be restricted imposing $\chi^2 = \left( \frac{R(D) - R(D)_{\exp}}{\Delta R(D)_{\exp}} \right)^2 + \left( \frac{R(D^*) - R(D^*)_{\exp}}{\Delta R(D^*)_{\exp}} \right)^2 \leq 1.0$. In this region we select the point corresponding to the minimum $|\tilde{e}^\mu_T|$, the black dot in fig. 6, together with the corresponding value for $e^\tau_T$, with numerical values $(\text{Re}(\tilde{e}^\mu_T), \text{Im}(\tilde{e}^\mu_T)) = (0.115, -0.005)$ and $(\text{Re}(\tilde{e}^\tau_T), \text{Im}(\tilde{e}^\tau_T)) = (-0.067, 0)$. This is a benchmark point used to describe the sensitivity of the angular observables and the pattern of correlated deviations from SM in this scenario. In correspondence to this value, the
fraction of longitudinally polarized $D^*$ measured by Belle in [50] is reproduced, considering the various uncertainties, while the fraction of tranversely polarized $D^*$ in the maximum recoil region turns out to deviate by more than $2\sigma$ in the last two bins of $w$. Indeed, this distribution is found to be SM-like: in SM for massless leptons the $D^*$ is fully longitudinally polarized at $q^2 = 0$. Compatibility with data in this kinematical region would be obtained for $\text{Re}(\epsilon_T^\mu) \leq 0.05$, in agreement with the findings in [32]. However, the purpose of our analysis is not to obtain the best fit of the NP coupling, a task deferred to different studies based on the full knowledge of the data sets with their systematics, but to provide the overview on how the various observables coherently deviate from SM in this scenario. It should be remarked that in the selected parameter region, for $\epsilon_T^\mu = \epsilon_T^\tau$, the ratio $R_{\epsilon\mu} = \frac{\mathcal{B}(\bar{B}^0 \to D^{*+}e^-\bar{\nu}_e)}{\mathcal{B}(\bar{B}^0 \to D^{*+}\mu^-\bar{\nu}_\mu)} = 1.04 \pm 0.05\pm 0.01$ [14] is reproduced: in figure 6, the shaded gray region is constrained by $R_{\epsilon\mu}$.

We compute the angular coefficients $I_\ell$ using the parameters $\epsilon_T^\mu$, $\epsilon_T^\tau$ in the low $\chi^2$ region in figure 6, with the results shown in figs. 7 and 8 for $\ell = \mu$ and $\ell = \tau$. Comparing the results in SM, the impact of NP is to modify the size of the coefficients, in several cases mainly near the maximum recoil point $w \to w_{\text{max}}$, as noticed in [32]. $I_7^\mu$ ($I_7^\tau$), always positive in SM, has a zero in NP. $I_7$ is displayed in figure 9; it is proportional to the lepton mass, hence it is small in the muon case, but it can be different from zero if $\epsilon_T^\ell$ has non-zero imaginary part.

Figure 5: SM distributions in $\cos \theta_V$ using CLN, with $\tilde{B} = B/B(D^* \to DF)$. The upper and lower plots refer to $\ell = \mu$ and $\ell = \tau$, respectively, the left and right column to $F = \pi$ and $F = \gamma$.

6 Scrutinizing deviations from SM

Starting from the set of angular coefficient functions, several observables can be constructed to scrutinize SM and possible anomalies. A few observables are independent of the $D^*$ decay mode.

- The $q^2$-dependent forward-backward (FB) lepton asymmetry is defined as

$$A_{FB}(q^2) = \left[ \int_0^1 d\cos \theta \frac{d^2 \Gamma}{dq^2 d\cos \theta} - \int_{-1}^0 d\cos \theta \frac{d^2 \Gamma}{dq^2 d\cos \theta} \right] / \frac{d\Gamma}{dq^2} \quad (49)$$

It can be expressed in terms of the coefficient functions:

$$A_{FB}(q^2) = \frac{3(I_{6c}^\pi + 2I_{6s}^\pi)}{6I_{1c}^\pi + 12I_{1s}^\pi - 2I_{2c}^\pi - 4I_{2s}^\pi} = \frac{3(I_{6s}^\gamma + 4I_{6c}^\gamma)}{6I_{1s}^\gamma + 24I_{1c}^\gamma - 2I_{2s}^\gamma - 8I_{2c}^\gamma} \quad (50)$$

and in SM in terms of the helicity amplitudes

$$A_{FB}(q^2)|_{SM} = \frac{3q^2 (H_+^2 - H_-^2) - 6m_H^2 H_0 H_t}{2m_t^2 (H_0^2 + 3H_t^2 + H_+^2 + H_-^2) + 4q^2 (H_0^2 + H_+^2 + H_-^2)} \quad (51)$$

- The transverse forward-backward (TFB) asymmetry is the FB asymmetry for transversely polarized $D^*$. In SM it is expressed in terms of the helicity amplitudes

$$A_{FB}^T(q^2)|_{SM} = \frac{3q^2 (H_+^2 - H_-^2)}{2(m_t^2 + 2q^2)(H_+^2 + H_-^2)} \quad (52)$$

$A_{FB}^T$ only depends on the form factor ratio $R_1$, hence it is useful to check the HQ prediction for such a quantity [51].
Figure 7: Angular coefficients in the fully differential decay distribution Eq. (30) for \( \ell = \mu \), with the tensor operator in the effective Hamiltonian and coupling \( \epsilon_T^\mu \) in the low \( \chi^2 \) region displayed in Figure 6.

- **\( D^* \) polarization asymmetry.** Defining the distributions \( d\Gamma_{L(T)}/dq^2 \) for longitudinally (L) and transversely (T) polarized \( D^* \), a polarization asymmetry can be defined:

\[
\frac{dA_{pol}^{D^*}(q^2)}{dq^2} = 2 \frac{d\Gamma_L}{dq^2} / \frac{d\Gamma_T}{dq^2} - 1 .
\]  

A combination regular at \( w \rightarrow w_{\text{max}} \) is

\[
\tilde{A}_{pol}^{D^*}(q^2) = \frac{dA_{pol}^{D^*}(q^2)}{dq^2} \div \frac{1}{1 + \frac{dA_{pol}^{D^*}(q^2)}{dq^2}} .
\]  

In SM this quantity is expressed in terms of the helicity amplitudes:

\[
\tilde{A}_{pol}^{D^*}(q^2)|_{SM} = 1 - \frac{(m_\ell^2 + 2q^2) (H_+^2 + H_-^2)}{6m_\ell^2 H_+^2 + 2(m_\ell^2 + 2q^2)H_0^2} .
\]
In figure 10 we depict the SM results for these observables and the NP ones obtained at the benchmark point \( \tilde{\epsilon}_\tau^\mu \) and \( \tilde{\epsilon}_\tau^\tau \). The SM results are systematically modified in NP; in particular, a zero appears in \( A_{FB}(w) \) when \( \ell = \tau \) \[22\]. \( \tilde{A}_{\mu}^D \) shows a high sensitivity to the tensor structure for \( w \to w_{\text{max}} \), in particular in the case \( \ell = \mu \), as noticed in \[32\], since in SM, for \( m_\ell \to 0 \), \( D^* \) is fully longitudinally polarized at this kinematical point.

An observable different when the final state involves a pion \( F = \pi \) or a photon \( F = \gamma \) is the

- **cos \( \theta_V \)-dependent forward-backward asymmetry**, defined as

\[
A_{FB}(\cos \theta_V) = \frac{\int_0^1 d\cos \theta \frac{d^2\Gamma}{d\cos \theta_V d\cos \theta} - \int_{-1}^0 d\cos \theta \frac{d^2\Gamma}{d\cos \theta_V d\cos \theta}}{\int_{-1}^1 d\cos \theta \frac{d^2\Gamma}{d\cos \theta_V d\cos \theta}}. \tag{56}
\]

Figure 11 shows the result in SM compared to NP for \( \tilde{\epsilon}_\tau^\tau \). The deviation from SM is largest for \( \cos \theta_V \simeq 0 \) in the case of pion, and for \( \cos \theta_V \simeq \pm 1 \) when \( F = \gamma \).
The sensitivity of the angular distributions to the $D^*$ polarization can be studied considering the triple differential distributions obtained from (30) and (31) after integration in the angle $\phi$. When $D^*$ is longitudinally polarized one has

\[
\frac{d^3\Gamma_L}{dq^2d\cos\theta_Vd\cos\theta} \bigg|_{F=\pi} = N_{\pi}|\vec{p}_{D^*}| \left(1 - \frac{m^2_\ell}{q^2}\right)^2 2\pi [I^\pi_{1c} + I^\pi_{2c} \cos 2\theta + I^\pi_{6c} \cos \theta] \cos \theta^2_V \tag{57}
\]

and for transversely polarized $D^*$ (summing over the two transverse polarizations)

\[
\frac{d^3\Gamma_T}{dq^2d\cos\theta_Vd\cos\theta} \bigg|_{F=\gamma} = N_{\gamma}|\vec{p}_{D^*}| \left(1 - \frac{m^2_\ell}{q^2}\right)^2 2\pi [I^\gamma_{1s} + I^\gamma_{2s} \cos 2\theta + I^\gamma_{6s} \cos \theta] \sin \theta^2_V, \tag{58}
\]

Double differential $D^*$ polarization fractions can be defined:

\[
F_L(\theta, \theta_V) = \frac{1}{\Gamma(\bar{B} \to D^*(DF)\ell^-\bar{\nu}_\ell)} \int_{q^2_{\min}}^{q^2_{\max}} dq^2 \frac{d^3\Gamma_L}{dq^2d\cos\theta_Vd\cos\theta} \tag{61}
\]

\[
F_T(\theta, \theta_V) = \frac{1}{\Gamma(\bar{B} \to D^*(DF)\ell^-\bar{\nu}_\ell)} \int_{q^2_{\min}}^{q^2_{\max}} dq^2 \frac{d^3\Gamma_T}{dq^2d\cos\theta_Vd\cos\theta}. \tag{62}
\]

These quantities keep the same angular dependence as in (57)-(60). In particular, they are symmetric under $\cos \theta_V \to -\cos \theta_V$, but they have no definite behavior when $\cos \theta \to -\cos \theta$, since the first two terms are invariant under this transformation, while the last one changes sign. In $F_L$ this term involves the angular coefficient $I^\pi_{6c}$ ($I^\gamma_{6s}$) proportional to the lepton mass: therefore, the distribution is expected to be nearly symmetric when $\cos \theta \to -\cos \theta$.
in the muon case, not for $\tau$. For SM this is shown in fig. 12. When $F = \pi$, the direction $\cos \theta_V = 0$, $\cos \theta = -1$ selects the transverse $D^*$ polarization, while for $\cos \theta_V = 1, \cos \theta = 0$ $D^*$ is longitudinally polarized. For $F = \gamma$, $F_L$ has a maximum at $\cos \theta_V = 0, \cos \theta = 0$, while $F_T$ is largest at $\cos \theta_V = 1, \cos \theta = -1$. The sensitivity to NP can be visualized integrating the double differential distributions in $\cos \theta$ or in $\cos \theta_V$. At the benchmark point, integrating over $\cos \theta$ we obtain $F_{L,T}(\theta_V) = \int_{-1}^{1} d\cos \theta F_{L,T}(\theta, \theta_V)$ in figs. 14 and 15. Integrating in $\cos \theta_V$, the distributions $F_{L,T}(\theta) = \int_{-1}^{1} d\cos \theta_V F_{L,T}(\theta, \theta_V)$ coincide for $F = \pi$ and $F = \gamma$: they are shown in fig. 10 in SM and NP case.

The observables for $\ell = \mu$ are more sensitive to NP: in the case of $F_L(\theta_V)$ the deviation is larger for $\cos \theta_V \simeq \pm 1$ for $F = \pi$, and for $\cos \theta_V \simeq 0$ for $F = \gamma$. Highest sensitivity to NP is in the function $F_T(\theta)$, which can probe the sign of the angular coefficient $I_{2s}^\pi (I_{2c}^\gamma)$ through its concavity. Indeed, the sign of the second derivative of $F_T(\theta)$ with respect to $\cos \theta$ depends on the sign of this coefficient, that is positive in SM but could have a different sign in other scenarios. Indeed, comparing figs. 7 and 2 one sees that NP can produce a sign reversal for this coefficient.

Tests of LFU

The angular coefficient functions in the fully differential distribution provide LFU tests. This is interesting, considering that after integration over the angles only four coefficients contribute to the decay rate, therefore only those are probed by ratios of branching fractions.

Information from the fully differential decay rate can be exploited defining

Figure 10: Observables defined in Eq. (49) (left column), (52) (middle) and (54) (right). The upper and lower plots refer to $\ell = \mu$ and $\ell = \tau$, respectively. The solid curves correspond to SM, the dashed ones to NP at the benchmark point $\bar{\epsilon}_T$. 
Figure 11: $\cos \theta_V$-dependent forward-backward asymmetry defined in (56). The upper and lower plots refer to $\ell = \mu$ and $\ell = \tau$, respectively, the left and right column to $F = \pi$ and $F = \gamma$. The solid curves correspond to SM, the dashed ones to NP at the benchmark point $\tilde{\epsilon}_T$.

\[
\tilde{I}_i = \left(1 - \frac{m_{\ell}^2}{q^2}\right)^2 |\vec{p}_{D^*}|_{BRF} I_i, \text{ and the ratios}
\]

\[
R_{\ell_1 \ell_2} = \frac{\int_{w=1}^{w_{max}(\ell_1)} (\tilde{I}_i^\pi (w)) \epsilon_{\ell_1} dw}{\int_{w=1}^{w_{max}(\ell_2)} (\tilde{I}_i^\pi (w)) \epsilon_{\ell_2} dw}
\]

for $\ell_1 \ell_2 = \mu \mu, \tau e, \mu e$. The SM predictions for these ratios, using CLN, are collected in Table 2. The errors reflect the form factor uncertainties. Since $I_{6c}^\pi$ is proportional to the lepton mass squared, the ratios $R_{6c}^{\mu e}$ are much larger than the others. Analogous ratios in the case of photon can be defined using (34). The same quantities predicted in the NP scenario are collected in Table 3. In the case of the ratios $R_{\mu e}^{\mu e}$, assuming $\epsilon_T^\mu = \epsilon_T^e$, a deviation with respect to the SM result would signal NP but not LFU violation.

Although the measurement of these ratios is challenging, the high statistics foreseen, e.g., at Belle II is promising [52]. For ratios involving the $\tau$ lepton, the use of the $\tau$ reconstruction through the three-prong decays, as done at LHCb, can result in improved signal-to-background ratio and in a higher statistical significance [53].
7 Conclusions

To understand the experimental results on semileptonic $B$ decays, the $R(D^{(*)})$ anomaly and the tension in the exclusive vs inclusive $|V_{cb}|$ determinations, it is mandatory to control the uncertainties in the SM predictions and to explore all possible ways in which deviations can be observed. Considering the angular coefficient functions in the fully differential decay distribution in $\bar{B} \rightarrow D^*\ell^–\bar{\nu}_\ell$, with $D^*$ decaying either as $D^* \rightarrow D\pi$ or as $D^* \rightarrow D\gamma$, we have studied several observables able to discern effects of the form factor parametrization and to identify the cases with minimal sensitivity to hadronic uncertainties, useful to pin down deviations.

Table 2: SM predictions for the ratios in Eq.(63) using CLN.
As a testing example, we have considered a NP model with a tensor operator.

Comparing the results obtained using the CLN and the BGL parametrization, we have identified the angular coefficients less sensitive to the parametrization. We have worked out relations allowing to extract the form factors from measured angular coefficients. Moreover, the relations between the angular coefficients for $D^*$ decaying to $\pi$ and to $\gamma$ can be used as

\end{table}
tests, exploiting the complementary of the two modes.

Considering the SM extension, we have shown that some angular coefficients, absent in the SM, can be found in NP. A number of observables display peculiar features in the NP model, e.g. the $q^2$-dependent forward-backward asymmetry for $\tau$, and the $\theta_V$-dependent forward-backward asymmetry both for $\ell = \mu$ and for $\ell = \tau$. The $D^*$ transverse polarization fraction $F_T(\theta)$ for $\ell = \mu$ is sensitive to the sign of one of the angular coefficients, different in SM and NP. Finally, ratios to probe LFU and show possible violations have been constructed. Although the measurement of several observables is challenging, the perspectives provided by the forthcoming analyses at LHCb and Belle II are surely encouraging.

Acknowledgements. We thank M. Rotondo for discussions, and M. Jung and D. Straub for comments. This study has been carried out within the INFN project (Iniziativa Specifica) QFT-HEP.

A Four-body phase-space

We remind that the four-body phase-space integration can be carried out using the identities

$$d\Pi_4 = \frac{1}{2m_B} \left[ dk_1 [dk_2] [dp_D][dp_F] (2\pi)^4 \delta^4(p_B - p_D - p_F - k_1 - k_2) \right]$$

$$= \frac{(2\pi)^4}{2m_B} \left[ \delta^4(p_B - q - p_D^\ast) \right] \times$$

$$\left[ [dk_1][dk_2]\delta^4(q - k_1 - k_2) \right] \times \left[ [dp_D][dp_F]\delta^4(p_D^\ast - p_D - p_F) \right]$$

$$= \frac{(2\pi)^4}{2m_B} d\Pi_2^{q,p_D^\ast} \times d\Pi_2^{k_1,k_2} \times d\Pi_2^{p_D,p_F}, \quad (64)$$
using the notation $[dp] = \frac{d^3p}{(2\pi)^32p^0}$. $d\Pi_2^{(k_1,k_2)}$ and $d\Pi_2^{(pD',pF)}$ are the two-body phase-spaces

$$d\Pi_2^{(k_1,k_2)} = \frac{1}{(2\pi)^6} \frac{1}{4\sqrt{q^2}} |\vec{k}_1|_{LRF} d\Omega_L$$

$$d\Pi_2^{(pD',pF)} = \frac{1}{(2\pi)^6} \frac{1}{4\sqrt{p_{D*}^2}} |\vec{p}_{D*}|_{D*RF} d\Omega_D .$$

In (65), $|\vec{k}_1|_{LRF} = \frac{q^2 - m^2}{2\sqrt{q^2}}$ is the lepton three-momentum in the lepton-pair rest-frame, and $d\Omega_L = d\cos\theta d\phi$. In (66), $|\vec{p}_{D*}|_{D*RF}$ is the $D$ three-momentum in the $D^*$ rest-frame, and $d\Omega_D = (2\pi)d\cos\theta_V$, with $\theta_V$ the angle between the $D$ momentum in the $D^*$ rest-frame and the $z$ axis; the integration over the azimuthal angle in this frame is trivial. $d\Pi_2^{(q,pD*)}$ can be evaluated exploiting the narrow width approximation (23):

$$d\Pi_2^{(q,pD*)} \delta(p_{D*}^2 - m^2_{D*}) = \frac{\pi}{m_B} |\vec{p}_{D*}|_{BRF} dq^2 ,$$

where $|\vec{p}_{D*}|_{BRF}$ is the $D^*$ three-momentum in the $B$ rest-frame.
B Hadronic matrix element parametrizations

In the CLN parametrization [13] the $B \to D^*$ matrix elements are written as

$$\langle D^*(v', \epsilon) | \bar{c} \gamma_{\mu} b | B(v) \rangle = \sqrt{m_B m_{D^*}} i \epsilon_{\mu \nu \alpha \beta} \epsilon^{\nu} v^\alpha v^\beta , \quad (68)$$

$$\langle D^*(v', \epsilon) | \bar{c} \gamma_{\mu} \gamma_5 b | B(v) \rangle = \sqrt{m_B m_{D^*}} \left[ h_{A_1}(w)(w + 1) \epsilon^\mu - [h_{A_2}(w) v_{\mu} + h_{A_3}(w) v_{\mu}'] (\epsilon^\ast \cdot v) \right] , \quad (69)$$

$$\langle D^*(v', \epsilon) | \bar{c} \sigma_{\mu \nu} b | B(v) \rangle = - \sqrt{m_B m_{D^*}} \epsilon_{\mu \nu \alpha \beta} \left[ h_{T_1}(w) \epsilon^{\ast \alpha}(v + v')^\beta + h_{T_2}(w) \epsilon^{\ast \alpha}(v - v')^\beta + h_{T_3}(w) v^\alpha v^\beta (\epsilon^\ast \cdot v) \right] , \quad (70)$$

with $v$ and $v'$ the $B$ and $D^*$ four-velocities and $w = v \cdot v'$. The factor $\sqrt{m_B m_{D^*}}$ accounts for the mass-dependent normalization of the states (in [13] the mass-independent normalization is adopted). This parametrization is related to the one in (25)-(26) through

$$V(q^2) = \frac{m_B + m_{D^*}}{2 \sqrt{m_B m_{D^*}}} h_V(w) \quad (71)$$

$$A_1(q^2) = \sqrt{m_B m_{D^*}} \frac{w + 1}{m_B + m_{D^*}} h_{A_1}(w) \quad (72)$$

$$A_2(q^2) = \frac{m_B + m_{D^*}}{2 \sqrt{m_B m_{D^*}}} \left[ h_{A_3}(w) + \frac{m_{D^*}}{m_B} h_{A_2}(w) \right] \quad (73)$$

$$A_0(q^2) = \frac{1}{2 \sqrt{m_B m_{D^*}}} \left[ m_B(w + 1) h_{A_1}(w) - (m_B - m_{D^*}) h_{A_2}(w) - (m_B w - m_{D^*}) h_{A_3}(w) \right] , \quad (74)$$

and

$$T_0(q^2) = - \frac{(m_B + m_{D^*})^2}{m_B m_{D^*}} \sqrt{\frac{m_{D^*}}{m_B}} h_{T_3}(w) \quad (75)$$

$$T_1(q^2) = \sqrt{\frac{m_{D^*}}{m_B}} (h_{T_1}(w) + h_{T_2}(w)) \quad (76)$$

$$T_2(q^2) = \sqrt{\frac{m_B}{m_{D^*}}} (h_{T_1}(w) - h_{T_2}(w)) \quad (77)$$

with $q^2 = m_B^2 + m_{D^*}^2 - 2 m_B m_{D^*} w$. The form factors $T_3, T_4, T_5$ in (26) are related to $T_0, T_1, T_2$ by the identity: $\sigma_{\mu \nu} \gamma_5 = \frac{i}{2} \epsilon_{\mu \nu \alpha \beta} \sigma^{\alpha \beta}$. The relations of the form factors in (68) to the Isgur-Wise function, $h_V(w) = h_{A_1}(w) = h_{A_2}(w) = h_{T_1}(w) = \xi(w)$ and $h_{A_3} = h_{T_2} = h_{T_3} = 0$ hold in the HQ limit. Such relations can be improved including radiative $\alpha_s$ and power $\frac{1}{m_b}, \frac{1}{m_c}$...
corrections. In the case of the functions in (69) they have been worked out in [13, 51]:

\[ h_V(w) = \left[ C_1 + \epsilon_c(L_2 - L_5) + \epsilon_b(L_1 - L_4) \right] \xi(w) \]
\[ h_{A_1}(w) = \left[ C_1^g + \epsilon_c \left( L_2 - \frac{w - 1}{w + 1} L_5 \right) + \epsilon_b \left( L_1 - \frac{w - 1}{w + 1} L_4 \right) \right] \xi(w) \]
\[ h_{A_2}(w) = \left[ C_2^g + \epsilon_c(L_3 + L_6) \right] \xi(w) \]
\[ h_{A_3}(w) = \left[ C_3^g + \epsilon_c(L_2 - L_3 - L_5 + L_6) + \epsilon_b(L_1 - L_4) \right] \xi(w) \]  

(71)

The coefficients \( C_i \) incorporate the radiative corrections. \( L_i \) account for \( O(1/m_Q) \) corrections in the HQ expansion, and their numerical values have been obtained using QCD sum rule determinations of the subleading form factors \[51\]. Their expressions can be found in the original papers \[13,51\], and are collected in the appendix of \[22\]. The analogous relations for the form factors in (70) have been worked out in \[42\].

The BGL parametrization uses the form factors \( g, f, a_+ \) and \( a_- \):

\[ \langle D^*(p', \epsilon) | \bar{c} \gamma_\mu b | \bar{B}(p) \rangle = i \epsilon_{\mu \nu \alpha \beta} \epsilon^{* \nu} p'^\alpha p^\beta g \]
\[ \langle D^*(v', \epsilon) | \bar{c} \gamma_\mu \gamma_5 b | \bar{B}(v) \rangle = \epsilon^* f + (\epsilon^* \cdot p) [(p + p')_\mu a_+ + (p - p')_\mu a_-] \]  

(72)

so that

\[ g(w) = \frac{h_V(w)}{\sqrt{m_B m_D^*}} \]
\[ f(w) = \sqrt{m_B m_D^*} (1 + w) h_{A_1}(w) \]
\[ a_+(w) = - \frac{m_D^*}{2 \sqrt{m_B m_D^*}} \left( \frac{h_{A_3}(w)}{m_D^*} + \frac{h_{A_2}(w)}{m_B} \right) \]
\[ a_-(w) = \frac{m_D^*}{2 \sqrt{m_B m_D^*}} \left( \frac{h_{A_3}(w)}{m_D^*} - \frac{h_{A_2}(w)}{m_B} \right) \]  

(73)

The expressions of the helicity amplitudes are:

\[ H_0 = \frac{\mathcal{F}_1(w)}{\sqrt{q^2}} \]
\[ H_\pm = f(w) \mp m_B m_D^* \sqrt{w^2 - 1} g(w) \]  

(74)

with

\[ \mathcal{F}_1(w) = \sqrt{m_B m_D^*} (1 + w) [(m_B w - m_D^*) h_{A_1}(w) - m_D^* (w - 1) h_{A_2}(w) - m_B (w - 1) h_{A_3}(w)]. \]

In the BGL approach, the observation is used that the \( W \) production amplitude of \( \bar{B} D^* \) is related to the \( \bar{B} \to D^* \) form factors by analytic continuation from the semileptonic region \( m_\ell^2 \leq t \leq t_\ast \) to the region \( t_+ \leq t \) with \( t_+ = (m_B \pm m_{D^*})^2 \) \[15\] \[17\]. In the production region, constraints can be imposed using perturbative QCD, including quark and gluon condensate corrections. Then, analyticity is exploited. The form factors are written as functions of the
conformal variable \( z \) in the form:

\[
f(z) = \frac{1}{P_f(z)} \sum_{n=0}^{N} a_n z^n.
\]

The Blaschke factors \( P_f(z) \) account for the \( t < (m_q + m_p)^2 \) poles associated with on-shell production of \( c\bar{b} \) bound states, while \( \phi_f(z) \) are outer functions from phase-space integration. The coefficients \( a_n \) satisfy unitarity bounds of the type

\[
\sum_{n=0}^{N} |a_n|^2 \leq 1.
\]

For \( B \to D^* \), three coefficients \( a_{n=0,1,2} \) have been fitted for each form factor \( g, f, F_1 \), and unitarity bounds have been imposed for each form factor. The masses of the \( c\bar{b} \) lowest-lying bound states with suitable \( J^P \) quantum numbers are taken from constituent quark models. The resulting values of the parameters are reported in [18].
