Introduction: To determine the immunostimulatory potential of crude extracts of *Warburgia ugandensis* subsp. *ugandensis* with a soluble leishmanial antigen in vaccinating BALB/c mice.

Methods: Seventy two female BALB/c mice were randomly assigned into six groups. The mice were vaccinated with soluble *leishmania* antigens (SLA) alone, hexane, ethyl acetate, and dichloromethane extract co-administered with SLA. Unvaccinated mice formed the control group. The induction of cell-mediated immunity following vaccination was determined by measuring in vitro lymphocyte proliferation and the production of interleukin (IL)-4 and gamma interferon (IFN-γ) determined by flow cytometry. Protection against *L. major* was determined by quantifying parasite burdens in *L. major* infected footpads using a limiting dilution assay and by measuring lesion sizes of the infected footpad compared to the contralateral uninfected footpad.

Results: On vaccination with extracts of *W. ugandensis* subsp. *ugandensis* alone or as adjuvants when used in combination with *Leishmania* antigens, the hexane extract and the dichloromethane extract plus SLA stimulated moderate production of IFN-γ and low levels of IL-4. These mice were partially protected from cutaneous leishmaniasis as shown by the slow development of lesions and comparatively less parasite burdens.

Conclusion: These data suggest that extracts of *W. ugandensis* subsp. *ugandensis* are suitable adjuvants for *Leishmania* vaccines. However, since *W. ugandensis* subsp. *ugandensis* has been shown to be effective against *Leishmania* parasites in vitro and in vivo, further studies ought to be conducted to determine its immunotherapeutic potential when co-administered with a soluble leishmanial antigen in vaccinating BALB/c mice.

Introduction

Leishmaniasis is a parasitic disease caused by protozoa of the genus *Leishmania* transmitted by the bite of infected phlebotomine sand flies. It encompasses a wide spectrum of clinical manifestations ranging from chronic cutaneous ulcers to fatal visceral infection. The World Health Organization estimates that at least 350 million people are at risk of the disease worldwide, 12 million people are infected with *Leishmania* parasites, and two million new cases of leishmaniasis occur each year in 88 countries in parts of Africa, India, the Middle East, southern Europe, and Central and South America [1].

The primary challenge associated with the treatment of leishmaniasis is that the drugs of choice are highly toxic, expensive and require hospitalization for more than three weeks. They include pentostam, pentamidine, miltefosine, and paromomycin. There are efforts towards the development of drugs based on natural products which are deemed to be safe. In this regard, medicinal plants offer prospects for discovering new compounds with therapeutic properties.

*Warburgia ugandensis* subsp *ugandensis* Sprague, the East African greenheart(Canellaceae) is one of the most highly utilized medicinal plants in tropical and subtropical Africa and is now highly endangered in the wild [2-3].The dried bark of the tree is commonly chewed and the juice swallowed as a remedy for stomach ache, constipation, tooth-ache, venereal diseases, cough, fever, muscle pains, weak joints and general body pains. The leaf decoction baths are used as a cure for skin diseases while the bark, roots or leaves can be boiled in water and drunk to treat malaria, although this causes violent vomiting. *Warburgia ugandensis* subsp *ugandensis* is also known as “soket” in Tugen tribe is used by traditional healers to treat VL (W. Tonui, personal communication). The stem barks are taken orally in boiled water or soup. Previous studies on *W. ugandensis* subsp *ugandensis* have shown good antibacterial, antifungal, antiviral activity and trypanocidal effects. For example, crude extracts and purified compounds of *W. ugandensis* subsp *ugandensis* showed activity against *Mycobacterium tuberculosis* H37Rv and *M. Bovis BCG Pasteur* [4], *Candida albicans* and measles virus [5]. Similarly, the
activity of *W. ugandensis* subsp *ugandensis* against trypanosomes has been demonstrated [5-6]. However, there is limited information on the immuno-
stimulatory effects of the plant. The objective of the present study was to
determine the immunostimulatory effects of extracts of *W. ugandensis*
subsp *ugandensis* against *Leishmania major* and *L. donovani* in BALB/c.

Methods

Collection of *W. Ugandensis* subsp *ugandensis* plant materials

*Warburgia ugandensis* subsp *ugandensis* stem barks were collected from
Sesia village in Kabarnet, Baringo District, in the Rift Valley Province in
Kenya. Sesia village is located 265 km northwest of Nairobi on the Tugen
Hills on the western edge of the Rift Valley (Grid Reference 056 947 on
the 1:50,000 sheet 104/1 Kipkabus). Botanical identification was carried
out by botanists from the National Museum of Kenya.

Preparation and extraction of *W. Ugandensis* subsp *ugandensis* extracts

The stem barks were cut into small pieces and air-dried for three weeks.
The dried specimens were shred using an electrical mill in readiness for
extraction. The sample preparation and extraction was carried out as
described by Harborne [7]. Successive extraction by Harborne [7]. Successive
extractions were carried out on the plant material with distilled organic
solvents of increasing polarity, which included n-hexane, dichloromethane,
etanol and methanol.

Three hundred grams of the shredded stem barks were weighed and put in
1 litre conical flasks. Six hundred millilitres of n-hexane was added and
soaked for 48 hours. The residue was filtered using a Buchner funnel
under vacuum until the sample dried. The sample was soaked further
with 600 ml of n-hexane for 24 hours until the filtrate remained clear. The
filtrate was then concentrated under vacuum by rotary evaporation at 30-
35°C to yield a brown residue [7]. The brown residue was transferred to a
sample bottle and dried under vacuum; the weight of the dry extract was
recorded and stored at -20°C until required for bioassay. The process was
repeated sequentially for dichloromethane, ethanol acetate and methanol.

Bioassays

Six week-old BALB/c mice were obtained from KEMRI’S animal house
facility and used for the in vivo studies. These experiments were carried
out in compliance with all relevant KEMRI institutional policies.

In Vitro parasite culture for *L. Major*

Metacyclic promastigotes of *L. Major* strain (Strain IDU/KE/83 = NLB-144)
and *L. donovani* strain (NLB-065) were used. Parasites were maintained
as previously described by Titus et al. [8] and metacyclics were
isolated from stationary phase cultures by negative selection using
dichloromethane [9]. Stationary-phase promastigotes were obtained from
5 to 7-day-old cultures. The cultures were made in T25 sterile
disposable culture flasks (25 ml) and incubated at 25°C as recommended
by Evans et al. [1989] [10] to stationary metacyclic stage.

Preparation of extracts for bioassays

Stock solutions of the extracts were made in culture media for anti-
leishmanial assay and re-sterilized by passing through 0.22 µm micro-
filters under sterile conditions in a laminar flow hood. The extracts that
were insoluble in water or media were first dissolved in 1% DMSO to
filters under sterile conditions in a laminar flow hood. The extracts that
were insoluble in water or media were first dissolved in 1% DMSO to

Results

Lymphoproliferative responses of splenocyte cultures before and after infection with *L. major*

The proliferative responses of splenocyte cultures to SLA obtained from
the experimental groups were done by Student’s t test. P values of ≤0.05
were considered significant. The proliferative responses of splenocyte cultures to SLA obtained from
the experimental groups were done by Student’s t test. P values of ≤0.05
were considered significant.

Statistical analysis

Data were recorded in Microsoft Excel and imported into SPSS 13.0
for analysis. All experiments were carried out in triplicate. The mean
and standard deviation of at least three experiments were determined.
Statistical analysis of the differences between mean values obtained for
the experimental groups were done by Student’s t test. P values of ≤0.05
or less were considered significant.

Infection of mice, treatment and determination of parasite numbers in cutaneous lesions

Female BALB/c mice were infected in the hind footpad with 1 x 106
*L. major* metacyclic promastigotes. In all experiments, treatment was
initiated 4 or 5 weeks after infection had established as determined by
the presence of lesions [12]. Lesion development was followed by
measuring the thickness of the infected footpad as compared to the
thickness of the same footpad prior to infection using a vernier caliper.
Disease progression in mice was evaluated by measuring lesion sizes for
a period of eight weeks on a week-to-week basis. At 1, 2 and 4-weeks
post infection, duplicate mice were sacrificed to estimate the parasite
burden in the footpads using a limiting dilution assay (LDA) [14]. Mice
that were not vaccinated formed the control groups.

The extracts were injected intraperitoneally. The untreated group
received Phosphate buffered saline. Lesion development was followed by
measuring thickness of the infected footpad as compared to the
thickness of the contralateral footpad prior to infection using a vernier
caliper. All mice were sacrificed during the 12th week, spleens weighed
and impression smears made. These were fixed in absolute methanol
and stained with Giemsa before examination for parasites to determine
whether or not visceralization of the parasite had taken place.

Immunostimulatory effects of crude extracts derived from *W. Ugandensis* subsp. *Ugandensis*

To test the immunostimulatory effects of the crude extracts, soluble
*Leishmania* antigens (SLA) were used. Female BALB/c mice in groups of
five were vaccinated by subcutaneous (i.c.) injection of 100 µg of SLA
alone, 100 µg of test sample alone or with 100 µg of SLA plus 100 µg of
test sample [9].

Cell cultures, proliferation of cytokine producing cells and measurement of cytokines

Spleens from mice infected with *L. Major* were harvested in each
experimental group on day 0 and at days 7, and 21 post-infection. Mice
were killed by cervical dislocation and the spleens were harvested and
processed as described in detail. The spleens were digested enzymatically
with 100 µg/ml antipapain, 50 µg/ml aprotinin and 1.6 mMphenylmethylsulfonyl
flouride (PMSF) (Sigma Chemicals Co.). The suspension was incubated
for 10 min on ice and sonicated for 10 periods of 30 seconds each
lengths initiated 4 or 5 weeks after infection had established as determined
by the presence of lesions [12]. Lesion development was followed by
measuring the thickness of the infected footpad as compared to the
thickness of the same footpad prior to infection using a vernier caliper.

SLA=Soluble Leishmania antigen; HEX=Hexane; DCM=Dichloromethane; ETAC=Ethyl acetate; HEX/SLA=Hexane/SLA; ETAC/SLA=Ethyl acetate/SLA; DCM/SLA=Dichloromethane/SLA; PBS=Phosphate Buffered Saline
For mice vaccinated with hexane extract, the size of lesions were significantly higher (P< 0.001) compared to that of the unvaccinated control. The production of IL-4 by splenocytes from mice vaccinated with hexane extract, dichloromethane, ethyl acetate and control (PBS) group alone during the course of infection was significantly lower (P<0.05) compared to the control unvaccinated group. The mean production of IL-4 by splenocytes of mice vaccinated with hexane extract, dichloromethane extract, ethyl acetate, ethyl acetate plus SLA and dichloromethane plus SLA in response to in vitro stimulation with SLA before challenge was significantly higher (P<0.05) compared to the control unvaccinated group (Table 2). The mean production of IFN-γ by splenocytes of mice vaccinated with SLA, hexane extract, dichloromethane extract, ethyl acetate, hexane plus SLA, ethyl acetate plus SLA, and dichloromethane plus SLA in response to in vitro stimulation with SLA before challenge was significantly higher (P<0.05) compared to the control unvaccinated group.

### Table 4: Parasite burden in the infected footpads of mice treated with BCG, SLA, hexane extract, dichloromethane extract, ethyl acetate extract and control (PBS) group alone during the course of infection

| Experimental groups | (No. of L. major(10^6))/footpad (95% confidence limits) |
|---------------------|--------------------------------------------------------|
| Day | Control | SLA | Hexane extract | Dichloromethane extract | Ethyl acetate extract |
| 14 | 10.5 (28.9-2.67) | 11.4 (18.31-3.16) | 6.99 (13.6-1.71) | 12.6 (17.8-9.61) | 14.3 (16.1-5.28) |
| 35 | 20.4 (37.35-13.83) | 18.4 (27.7-12.25) | 8.27 (21.01-3.38)* | 25.8 (31.74-17.2) | 23.6 (32.78-16.9) |
| 56 | 69.8 (98.1-38.44) | 52.3 (72.37-19.4)* | 9.33 (7.20-0.93)* | 53.5 (82.5-21.37)* | 48.8 (62.1-39.04) |

*P<0.05 Parasite burden is significantly different from that of the unvaccinated control.

### Table 5: Parasite burden in the infected footpads of mice treated with hexane/SLA, dichloromethane/SLA, ethyl acetate/SLA and control (PBS) group alone during the course of infection

| Experimental groups | (No. of L. major(10^6))/footpad (95% confidence limits) |
|---------------------|--------------------------------------------------------|
| Day | Control | Hexane/SLA extract | Ethyl acetate/SLA extract | Dichloromethane/SLA extract |
| 14 | 10.5(28.9-2.67) | 9.25(24.7-3.39) | 11.7(19.6-6.94) | 9.25(10.7-1.12)* |
| 35 | 20.4(37.35-13.83) | 19.03(31.62-14.56) | 20.97(26.8-15.72) | 8.11(10.16-1.37)* |
| 56 | 69.8(98.1-38.44) | 48.83(87.21-29.73)* | 63.7(88.9-38.7) | 6.78(7.39-0.96)* |

*P<0.05 Parasite burden is significantly different from that of the unvaccinated control.

Compared to the proliferation before infection (P<0.05).

**Interferon gamma production by splenocyte cultures before and after infection with L. major**

The mean production of IFN-γ by splenocytes of mice vaccinated with SLA, hexane extract, dichloromethane extract, ethyl acetate, hexane plus SLA, ethyl acetate plus SLA, and dichloromethane plus SLA in response to in vitro stimulation with SLA before challenge was significantly higher (P<0.05) compared to the control unvaccinated group (Table 2). The mean production of IFN-γ by splenocytes of mice vaccinated with SLA, hexane extract, dichloromethane extract, ethyl acetate, hexane plus SLA, ethyl acetate plus SLA, and dichloromethane plus SLA in response to in vitro stimulation with SLA before challenge was significantly higher (P<0.05) compared to the control unvaccinated group.

**Interleukin - 4 production by splenocyte cultures before and after infection with L. major**

The mean production of IL-4 by splenocytes of mice vaccinated with SLA, hexane extract, dichloromethane extract, ethyl acetate, ethyl acetate plus SLA, and dichloromethane plus SLA in response to in vitro stimulation with SLA before challenge was significantly higher (P<0.05) compared to the control unvaccinated group. The mean production of IL-4 by splenocytes of mice vaccinated with hexane extract, dichloromethane extract, ethyl acetate and dichloromethane plus SLA in response to in vitro stimulation with SLA before challenge was significantly lower (P<0.05) compared to the control unvaccinated group.

The production of IL-4 by splenocytes from mice vaccinated with hexane plus SLA was not significantly different (P=0.245) from that of the unvaccinated control (Table 3), while the levels of production of IL-4 for mice vaccinated with ethyl acetate extract plus SLA and SLA were significantly higher (P< 0.001) compared to that of the unvaccinated control.

**Lesion size measurements for BALB/c mice vaccinated before infection with L. major**

For mice vaccinated with hexane extract, the size of lesions were significantly smaller (P<0.05) than those of the unvaccinated controls from week 2 to week 8. For mice vaccinated with dichloromethane extract, ethyl extract, hexane extract plus SLA and ethyl acetate extract plus SLA there was no significant difference (P>0.05) between the lesion sizes of these mice compared to those of the unvaccinated controls from week 2 to week 8 (Table 4).

Mice in the control unvaccinated and L. major challenged group developed large progressive footpad lesions reaching a peak at week (mean ± S.E., 0.947 ± 0.022) mm. Unvaccinated control groups were euthanatized if they reached a predetermined level of lesion severity and/or displayed clinical signs of distress or pain.

**Quantification of L. major in infected footpads of BALB/c mice vaccinated before and after infection with L. major**

The number of L. major parasites present in the infected footpads was quantified at 14, 35 and 56 days post infection using a limiting dilution assay (LDA) [15]. The results were analyzed using the ELIDA statistical package (2001-2005). In the first LDA done at 14 days post infection, L. major parasites were detected in both the vaccinated and unvaccinated groups of mice. The number of L. major in the footpads from mice vaccinated with dichloromethane extract plus SLA (9.25 8tgme; 106) was significantly lower (P<0.05) than that of the controls (10.5 ± 106) at 14 days post infection. However, there was no significant difference (P<0.05) in the number of parasites for the rest of the groups compared to the unvaccinated control (Table 5).

The parasite burdens in the mice vaccinated with hexane extract (8.27 x 106) and dichloromethane extract plus SLA (8.11 x 106) were significantly lower (P< 0.05) from those of the control unvaccinated mice as the disease progressed as quantified at day 35. On the 14th day, there was no significant difference (P>0.05) in the number of parasites for the rest of the groups compared to the unvaccinated control (Table 5).

By the 56th day, parasite burdens for themice vaccinated with hexane extract group (9.33 × 106) and the dichloromethane plus SLA group (6.78 × 106) reduced significantly (P<0.005) compared to those of the unvaccinated control group (69.8 × 106). Similarly, parasite burdens for
the SLA group (52.3 × 106), dichloromethane group (53.5 × 106), ethyl acetate group (48.8 × 106), hexane plus SLA group (48.8 × 106) and ethyl acetate plus SLA group (63.7 × 106) reduced significantly (P<0.05) compared to the vaccinated controls (69.8 × 106). The parasite burdens of the dichloromethane, and the dichloromethane plus SLA were significantly lower (P< 0.005) compared to those of the SLA group, dichloromethane group, ethyl acetate group, hexane plus SLA group and ethyl acetate plus SLA group.

Discussion

The study focused on the immunostimulatory activities of the crude extracts of a native medicinal plant used by traditional healers in Kenya. The limitation of the study is that the active principles responsible for the immunostimulatory responses observed were not identified. Further, the mechanisms of the immunostimulatory activities were not elucidated.

Our results show that organic extracts of *W. ugandensis* subsp *ugandensis* can induce lymphocyte proliferation to SLA on their own or enhance such response if co-administered with SLA in a vaccine. Lymphocyte proliferation is a crucial event in the activation of both cellular and humoral immune responses [17]. Proliferative responses of splenocytes to SLA have previously been used as a measure of exposure to the parasites, as well as a measure of protection [18]. Our results are consistent with previous studies that suggest that some plant products, such as artemisinin, induce proliferation of T-cells in vitro [19]. The enhanced proliferative responses for extracts co-administered with SLA in this study is consistent with findings of a previous study where mice vaccinated with SLA and TH1 promoting adjuvant had significantly higher stimulation indices compared to those vaccinated with SLA alone [18]. Thirty days post infection with *L. major* there was marked increase in the proliferative response to SLA for the groups vaccinated with SLA, hexane extract and dichloromethane extract plus SLA compared to the proliferation before infection indicating a recall proliferative response. For mice vaccinated with hexane extract plus SLA and the group vaccinated with ethyl acetate plus SLA, the proliferative responses of the splenocyte cultures to SLA was significantly lower. The reduction in the proliferative responses is probably an indication of immunosuppression caused by the combination of SLA with the plant extracts.

Extensive studies with experimental mouse models infected with *L. major* have shown that the outcome of infection with *Leishmania* parasites is critically dependent on the activation of one of the two subsets of CD4 T cells, Th1 and Th2 [20,21]. In the present study, IFN-γ was expressed in splenocytes, which is in agreement with the findings of other authors who have shown that this cytokine is important in the development of protective immune responses in experimental Leishmaniasis [22, 23]. Gamma interferon secreted by Th1 cells, is the most potent macrophage-activating cytokine leading to host resistance to infection with *Leishmania* parasites whereas IL-4 secreted by Th2 cells, is associated with down-modulation of IFN-γ-mediated macrophage activation [21].

In a previous study, 67 tannins were tested for antileishmanial and immunomodulatory potencies and shown to augment and prolong the activation of host defense mechanisms indicating that parasitized macrophages were "primed" to react to activating molecules such as phenol [24]. Further studies demonstrated the effects of IFN-γ, lipopolysaccharide (LPS), and some polyphenols as individual stimuli, as well as in various combinations on NO production in non-infected and infected macrophage-like RAW 264.7 with emphasis on the NO/parasite kill relationship. In non-infected and in *Leishmania* parasitized cells, gallic acid significantly inhibited the IFN-γ and LPS-induced NO detected in the supernatants [25]. This effect was less prominent in IFN-γ- and LPS-stimulated cells.

Elsewhere, it has been shown that the ethyl acetate portion of *Germium pyrenacum* induced significant production of IFN-γ and TNF [26]. The cytokine-inducing potential of the flavonoids glycosides decreased with increasing polarity [26]. The results provide evidence that flavonoids glycosides possess the capability to stimulate defense mechanisms in *leishmania*-infected RAW 264.7 cells, albeit with moderate potential. This is similar to the observation in the current study where the hexane extract (with low polarity) stimulated production of higher levels of IFN-γ compared to the ethyl acetate extract (higher polarity).

In experimental CL, it has been suggested that the healing of lesions depends on the early presence of macrophages, the activation of these cells by type 1 interferon and, later, by low amounts of IFN-γ probably produced by NK cells, consequently, the Th1 cells amplify the killing of the parasite when they release more IFN-γ [27]. Interferon-gamma is known to be a strong inducer of the macrophage enzyme inducible nitric oxide synthase (iNOS) [28], which mediates the production of nitric oxide that directly kills *L. major* [29].

Previous studies have demonstrated that CL is associated with the expansion of CD4+ T cells that contain high levels of IL-4 mRNA in the draining lymph nodes and spleen [30] and with elevated levels of immunoglobulin E, an IL-4-dependent immunoglobulin isotype [30]. Early production of IL-4 in mice correlates with the dominance of an IL-4-driven Th2 response that causes disease [21]. In the current study the parasite burdens for the SLA, hexane extract plus SLA and ethyl acetate plus SLA groups were comparable to those of the unvaccinated control group four weeks post infection. Indeed by the end of week eight, the lesion sizes of the mice in these groups were similar in size to those of the unvaccinated group indicating exacerbation of disease.

It is postulated that production of high levels of IL-4 interferes with the production or activity of IFN-γ. A number of mechanisms by which IL-4 may interfere with the production or activity of IFN-γ has been identified, including the direct inhibition of macrophage activation to kill intracellular amastigotes [31]. The ability of IL-4 to block the activation of macrophages has been most consistently demonstrated following prior treatment with IL-4. Indeed, administration of IL-4 after IFN-γ may activate macrophage anti-*L. major* activity [32].

These mice were partially protected from cutaneous leishmaniasis as shown by the slow development of lesions. Similar results were reported in immunized BALB/c mice with K+lectin of Artocarpus integrifolia associated, or not with SLA, and partial protection of the animals was observed after challenge with *L. amazonensis* [22].

Mice vaccinated with SLA, ethyl acetate extract, dichloromethane extract and the ethyl acetate plus SLA developed lesions and had higher parasitaemia comparable to the unvaccinated control group. This is in agreement with previous studies where immunization with SLA alone resulted in lesions almost as evident in the controls immunized with PBS [33,34].

Conclusion

These results suggested that extracts from *W. ugandensis* subsp *ugandensis* contained chemical compounds that possess positive and/or negative modulator effects on the immune system. *Warburgia ugandensis* subsp *ugandensis* has been used by traditional healers in Kenya for many years. The immunostimulatory effects of the plant can be used to explain the efficacy of this plant in addition to its direct effects on *Leishmania* parasites. Further studies on the mechanisms have potential of unveiling the possibility of targeting this plant for drug development that can be used for the treatment of leishmaniasis.
