ABSTRACT

An ultrafast route to prepare up-convertsing single β-phase NaYF₄:Yb³⁺,Ln³⁺ (Ln: Er, Tm or Tb) short nanorods (UCNRs) of high quality was developed. This new procedure affords reactive-surface nanorods that are easily coated by direct injection of suitable capping ligands. Thus, highly crystalline nanorods with excellent UC fluorescence and good solvent-selective dispersion are obtained, which represents a significant advance in the field and enlarges their use for biomedical and other technological applications. Unlike other methodologies, the short reaction time provides a kinetic control over crystallization processes and the β-phase and rod morphology is preserved regardless of the optically active Ln³⁺ ion. The UC emission was finely tuned by using the most popular Yb³⁺/Tm³⁺ and Yb³⁺/Er³⁺ pairs. More importantly, UCNRs doped with the unusual Yb³⁺/Tb³⁺ pair, with no ladder-like energy levels, provided a nice emission upon near infrared (NIR) excitation, which constitutes the first example of phonon-assisted cooperative sensitization to date in pure β-NaYF₄ nanocrystals.

TOC GRAPHICS
KEYWORDS. Microwave synthesis, up-conversion luminescence, fluoride nanocrystals, lanthanide doped nanomaterials.

Lanthanide co-doped β-NaYF₄ nanocrystals (Ln³⁺: Er,Tm,Yb) are high brightness near infrared to visible light up-converters with great interest in technological applications across many fields such as photonics, security, sensors, energy and biomedicine.¹⁻² Key for their effective industrial integration in commercial devices will be the prospect to fabricate monodisperse high-quality nanocrystals with nanometric size (<100 nm), well-defined shape of pure hexagonal (β) phase - which affords the highest optical emission- through a facile, cheap and fast scalable synthetic route. Furthermore, a one-pot processing to make solvent-soluble dispersions of the nanoparticles is highly desirable.³

Up-converting nanoparticles (UCNPs) are routinely prepared by thermal decomposition,⁴⁻⁷ co-precipitation,⁸⁻⁹ and hydro- or solvothermal¹⁰⁻¹¹ routes. However, harsh conditions such as high reaction temperature (>300 °C) and pressure, long reaction times (6-48h), and/or waterless oxygen-free conditions are usually required, hindering their industrial up-scaling. Furthermore, NaYF₄ crystallizes first as a metastable cubic α-phase with very poor optical activity. The cubic-to-hexagonal conversion needs to overcome a high free-energy barrier¹² and a subsequent fast growth of crystals occurs; thus, mixtures of both phases are usually obtained, especially in the case of small nanoparticles.

Microwave-assisted (MW) synthesis has appeared as an attractive way to prepare monodisperse colloids with complex kinetic/thermodynamic control over crystallization processes.¹³⁻¹⁴ Indeed, this route has already been employed to prepare different fluoride materials.¹⁵⁻¹⁷ However, the accurate attribution of the crystalline phase is difficult in small nanocrystals and even sometimes
avoided by the authors, since it is a crucial issue in highly sensitive luminescent systems. Reports concerning UC NaYF₄ encompass either small nanoparticles (< 8 nm) of the 10-times less efficient α-phase¹⁸⁻²⁰ and α/β mixtures,²¹ or pure β-phase prisms²⁰,²² and long wires²³ of micrometric size. Small nanorods of less than 100 nm, highly crystalline and pure β-phase by using a mild and fast microwave route have never been reported to our knowledge.

An additional advantage of our MW protocol is that a functional coating can be added upon completion of the reaction.²⁴ This allows great versatility in designing stable colloids in solvents of different polarity in sight of the envisaged application. For example, in biologically relevant applications such as bioimaging, drug targeting or nanothermometers, luminescent nanoparticles must be water dispersible to be compatible in physiological conditions.²⁵ By contrast, other technological applications need their dispersion in low boiling solvents such as cyclohexane in order to make thin films in miniaturized designs. This is the case for solar cells, optoelectronic devices or anti-counterfeiting systems.²⁶⁻²⁷

Here, we present a fast, energy efficient and versatile microwave route to successfully prepare pure β-NaYF₄:Yb³⁺,Ln³⁺ nanorods (NRs) surface coated for solvent-selective dispersions. Along with the so-characterized Er³⁺ and Tm³⁺ ions as Ln³⁺ activators, we focused also on Tb³⁺ ions since it shows an unusual up-conversion process. The distinctive energy level structure of Tb ions does not match with the 980 nm excitation. However, the long-lived excited ⁵D₄ level can be populated based on the energy migration mechanism²⁸ in which two adjacent Yb⁵⁺ ions cooperatively sensitisate one Tb⁵⁺ ion. This process have been demonstrated in Yb,Tb co-doped single crystals of SrCl₂²⁹ and ceramic glasses containing LiYbF₄,³⁰ NaLuF₄,³¹ and NaYF₄ nanocrystals but very scarcely reported on NaGdF₄ and α-NaYF₄ nanoparticles. This approach can also be extended to other lanthanide ions such as Eu³⁺, Dy³⁺, or Sm³⁺ and afford tuneable emissions spanning from
the UV to the visible spectral region. Thus, this simple and universal strategy to prepare NIR-activated fluorescent β-NaYF₄ nanorods represents a significant advance in the field.

Figure 1 summarizes the procedure to synthesize the up-converting nanorods; the details of the synthesis are included in the Supporting Information (SI). The precursors and solvent, F/Y ratio, and MW reaction conditions (T, t) have been judiciously modified to target nanometric dimensions and the single P6₃/m hexagonal phase, as shown in the XRD pattern of Figure 1. The reaction conditions investigated to attain the pure β-phase are summarized in Table SI1 and Figure SI1. The optimized synthesis employs benzyl alcohol and lanthanide acetates as solvent and Ln³⁺ precursors, respectively.

**Figure 1.** Schematic representation of the MW synthesis and post-treatment (PT) coating of the UCNR. XRD pattern of the β-NaYF₄:Yb,Tb³⁺ nanorods (β reference, JCPDS card 16-0334).

Benzyl alcohol and benzyl mercaptan have previously been employed to prepare metal oxides³⁵ and sulphides³⁶ by non-aqueous routes with good results in controlling particle size but never tried
for the synthesis of fluoride crystals. In such studies, the alcohol and mercaptan groups promoted the metal-oxygen-metal and metal-sulphur-metal bonds. The synthetic route reported in here is not analogous since the main roles of the benzyl alcohol is to act as suitable solvent in terms of solubility in water (4 g/100 mL), thermal stability (boiling point of 205°C) and probably as capping agent minimizing the nanocrystal aggregation. Although a detailed mechanistic study goes beyond the scope of this communication, the results will be shortly discussed.

The synthesis of the UC nanorods includes a pre-heating at 60 ºC to completely dissolve the lanthanide acetates and the sodium fluoride in the benzyl alcohol/water mixture (4/1 molar ratio). The use of lanthanide acetates instead of stearates, which are salts commonly employed in the synthesis of lanthanide-doped fluoride nanocrystals, favours the dissolution of the precursors, without significant coordinating effect of the acetate ligand. After 5 minutes at 60 ºC, the temperature is rapidly increased to 180 ºC and kept for 10 minutes. In this step, the kinetically controlled nucleation of α-NaYF₄ seeds and the nanocrystal growth promoting the α-to-β phase transformation takes place. Further growth of the thermodynamically favored β-NaYF₄ phase is drastically reduced by a fast cooling of the reactor.

We further take advantage of the particles surface reactivity just after the MW synthesis to graft hydrophilic, such as polyvinylpyrrolidone (PVP), or hydrophobic, such as oleic acid (OA), molecules on the particle’s surface. A functional coating was formed by simple injection of the capping ligands into the reaction tubes, which were kept at 80 ºC after the nanocrystals synthesis to better preserve their surface reactivity. We adopted this strategy instead of the addition of PVP or OA during the UCNRs synthesis because both molecules demonstrated to suffer oxidation or
degradation processes during the microwave treatment. The formation of PVP- and OA-capped UCNRs was verified by FTIR analysis (Figure S12). 39-41

Figure 2a shows a TEM image of the bare UCNRs doped with Tb, as an example. The particles exhibit an anisotropic morphology with rather uniform transversal size (or diameter) of around 15 nm and a longitudinal size distribution ranging between 30 and 100 nm (Fig. 2e). The rods appear stacked along the longitudinal axis forming small aggregates of few NRs. In accordance to the XRD results, the diffraction rings of the SAED patterns for the UCNRs (Fig. 2d) were indexed to the β-phase.
**Figure 2.** a,b,c) TEM images of the bare, PVP-coated and OA-coated UCNRs, respectively; d) SAED image from bare Tb-NRs; e) transversal and longitudinal size distribution of Tb-NRs; f) dispersion of the Tb-NRs in different solvents.

In comparison to previous reports in which MW routes are used to prepare small monodisperse \( \alpha \)-NaYF\(_4\) nanocrystals\(^1\), our synthesis of \( \beta \)-NaYF\(_4\) nanorods provides larger but less uniform particle sizes. The larger sizes are beneficial for the UC photoluminescence since it is well-established that the particle size dramatically influences the non-radiative properties (multiphonon
relaxation and energy transfer) reducing the UC efficiency drastically, from values of 13-14% to 0.001% in Er,Yb:NaYF\textsubscript{4} particles of few microns to few nanometers (<8 nm). This effect is related to the presence of defects at the surface of the nanocrystals.\textsuperscript{42,43} Regarding the less uniform morphology, we can find an explanation on the model of phase transition reported by M. Berry.\textsuperscript{38} We hypothesize that the size polydispersity would be related to small differences in the duration of the stage during which the α particle ripens, before β particles begin to appear. Therefore, it would be interesting to explore in the future if mild annealing conditions for long time can be used to refine nanomaterials shape. Anyway, the described methodology provides pure hexagonal nanorods in extremely short time (15 min) with excellent up-conversion luminescence intensity.

After coating with PVP molecules (see Fig. 2b), the small aggregates disappear and the nanorods are found isolated with an average inter-rods distance of ca. 8 nm, a distance compatible with a uniform PVP coating. In the case of OA-grafted NRs, the particles also appeared less aggregated than for the bare UCNR but the inter-rod distance is not so evident (Figure 2c). Figure 2f depicts the nanoparticles stability in polar and non-polar solvents. The as-obtained rods quickly sediment in all solvents (acetone is used here to illustrate this fact). In contrast, the rods coated with PVP are colloidally stable for months when dispersed in water; similarly, the particles coated with oleic acid remain well dispersed in cyclohexane.

Figure 3 shows that the hexagonal crystal phase and the rod-like morphology are maintained under the same reaction conditions independently of the emitting lanthanide ion employed (terbium, erbium and thulium). This fact highlights the universal kinetic control of the crystal growth in this MW-assisted synthesis; allowing us freedom of choice of multi-lined emissions. The figure also evidences the lanthanide-doping-mediated crystal growth process reported by F. Wang;\textsuperscript{44} where the dimensions of the NRs are little affected by the ionic radius and dipole
polarizability of the substitutional dopant ion (increasing ionic radius or polarizability Tm<Er<Tb).

**Figure 3.** TEM images and SAED patterns of PVP-UCNRs doped with a) Yb,Tb-, b) Yb,Er- and c) Yb,Tm- NaYF₄ hexagonal nanorods.

The MW-synthesized NaYF₄ nanorods exhibited excellent up-conversion emission. Figure 4 shows the photographs of the three-doped systems emitting visible light (mainly green and blue light at naked eye) upon 980 nm excitation. The UC emission spectra of PVP-coated nanorods are illustrated in Figure 4 left. The optical analysis was done in water suspensions for convenience since the emissions of the crystalline nanorods are hardly affected by the coating. The spectra display the characteristic emission bands from the f-f electronic transitions of Tb³⁺, Er³⁺ and Tm³⁺ ions ascribed in the spectra upon NIR irradiation. These transitions correspond to the well established UC mechanism for Er/Yb (two-photon absorption) and Tm/Yb (three-photon absorption) doping pairs⁴⁵, in which the efficient upconversion is associated to their ladder-like arranged energy levels facilitating the successive photon absorption (Figure 4 right).
Figure 4. Left: Images of the emission in powdered samples and relative UC emission spectra for water suspensions of a) PVP-UCNR(Tb), b) PVP-UCNR(Er) and c) PVP-UCNR(Tm) under 980-nm diode laser excitation. Right: Proposed energy transfer mechanisms in the Yb:NaYF$_4$ nanorods codoped with Tm$^{3+}$, Er$^{3+}$ and Tb$^{3+}$. The full arrows represent photon excitation and emission processes; while dotted and dashed arrows represent energy transfer and multiphonon relaxation processes, respectively. Corresponding CIE chromaticity coordinates of the UCNRs.

It is remarkable to see the intense manifold emissions from $^5$D$_4$, $^5$D$_3 \rightarrow ^7F_J$ ($J = 6, 5, 4, 3$) transitions of Tb$^{3+}$ generated by excitation of two Yb$^{3+}$ ions and simultaneous energy transfer at the ground state $^7F_6$, which then populates the excited $^5$D$_4$ and $^5$D$_3$ levels. To our knowledge, this is the first example of phonon assisted cooperative sensitisation in pure $\beta$-NaYF$_4$:Yb$^{3+}$,Tb$^{3+}$ to date.
The visible colour emission is efficiently tuned by changing the activator ion (Tm, Tb, Er), spanning from blue to green shades, as represented in the colour coordinates (Figure 4 right).

To sum up, this work reports a ultrafast, cheap and easily scalable microwave route to prepare pure hexagonal NaYF₄:Yb,Ln³⁺ nanorods of small size with strong upconversion luminescence. The process allows an easy coating with hydrophilic or hydrophobic molecules to render the rods dispersible in solvents of different nature. The crystal growth process is kinetically controlled by the short reaction time and permits the choice of multiple active ions (Er, Tm, Tb…) without strongly affecting the nanorods crystallinity, morphology or size. Thus, tuneable visible colours can be readily prepared by rational selection of the doping ions. Owing to their small size, excellent crystallinity and good dispersibility, these nanorods could be used for a wide range of application.

Therefore, it is expected that this simple and ultrafast route to prepare the so-used NaYF₄ nanocrystals will be warmly received by the big research community working on up-conversion nanomaterials.

ACKNOWLEDGMENT

This research was partially funded by the Spanish Ministry of Economy (MAT2015-64442-R, MAT2015-64139-C4-1-R, and SEV-2015-0496 projects, co-funded with European Social Funds) and Universitat Jaume I (P1B2014-21). F. G. thanks Generalitat Valenciana for his Grisolia PhD Fellowship. We thank Olatz Arriga, nanoscience and nanotechnology student at the UAB for her assistance in sample’ processing.
