MATRIX LIBERATION PROCESS
I: LARGE DEVIATION UPPER BOUND AND ALMOST SURE CONVERGENCE

YOSHIMICHI UEDA

Abstract. We introduce the concept of matrix liberation process, a random matrix counterpart of the liberation process in free probability, and prove a large deviation upper bound for its empirical distribution and several properties on its rate function. As a simple consequence we obtain the almost sure convergence of the empirical distribution of the matrix liberation process to that of the corresponding liberation process as continuous processes in the large $N$ limit.

1. Introduction

Let $M_N(\mathbb{C})^{sa}$ be all the $N \times N$ self-adjoint matrices endowed with the natural inner product $\langle A, B \rangle_{HS} := \text{Tr}_N(AB)$, and it has the following natural orthogonal basis:

$$C_{\alpha \beta} := \begin{cases} \frac{1}{\sqrt{2}}(E_{\alpha \beta} + E_{\beta \alpha}) & (1 \leq \alpha < \beta \leq N), \\ E_{\alpha \alpha} & (1 \leq \alpha = \beta \leq N), \\ \frac{1}{\sqrt{2}}(E_{\alpha \beta} - E_{\beta \alpha}) & (1 \leq \beta < \alpha \leq N). \end{cases}$$

Here, $\text{Tr}_N$ stands for the non-normalized trace (i.e., $\text{Tr}_N(I_N) = N$ with the identity matrix $I_N$) and the $E_{\alpha \beta}$ are $N \times N$ standard matrix units. Using these inner product and orthogonal basis we identify $M_N(\mathbb{C})^{sa}$ with the $N^2$-dimensional Euclidean space $\mathbb{R}^{N^2}$, when we use usual stochastic analysis tools on Euclidean spaces. Choose the $nN^2$-dimensional standard Brownian motion $B_{\alpha \beta}^{(i)}$, $1 \leq \alpha, \beta \leq N$, $1 \leq i \leq n$ with natural filtration $\mathcal{F}_t$, and define

$$H_{\alpha \beta}^{(i)}(t) := \sum_{\alpha, \beta=1}^{N} \frac{B_{\alpha \beta}^{(i)}(t)}{\sqrt{N}} C_{\alpha \beta}, \quad t \geq 0, \quad 1 \leq i \leq n,$$

which are called the $n$ independent $N \times N$ self-adjoint matrix Brownian motions on $M_N(\mathbb{C})^{sa}$. The stochastic differential equation (SDE in short)

$$dU_{\alpha}^{(i)}(t) = i dH_{\alpha}^{(i)}(t) U_{\alpha}^{(i)}(t) - \frac{1}{2} U_{\alpha}^{(i)}(t) dt \quad \text{with} \quad U_{\alpha}^{(i)}(0) = I_N, \quad 1 \leq i \leq n,$$

defines unique $n$ independent diffusion processes $U_{\alpha}^{(i)}$, $1 \leq i \leq n$, on the $N \times N$ unitary group $U(N)$, which are called the $n$ independent $N \times N$ left unitary Brownian motions. It is known, see e.g., [13, Lemma 1.4(2)] and its proof, that they satisfy the so-called left increment property, that is, the $U_{\alpha}^{(i)}(t)U_{\alpha}^{(i)}(s)^*$, $t \geq s$, are independent of $\mathcal{F}_s$ and has the same distribution as that of $U_{\alpha}^{(i)}(t-s)$. This property plays a crucial role throughout this article.

For each $1 \leq i \leq n + 1$, an $r(i)$-tuple $\xi_i(N) = (\xi_{ij}(N))_{j=1}^{r(i)}$ of $N \times N$ self-adjoint matrices is given. Throughout this article, we assume that the given sequence $\Xi(N) := (\xi_{ij}(N))_{i=1}^{n+1}$ are operator-norm bounded, that is, $\|\xi_{ij}(N)\| \leq R$ with some constant $R > 0$, and has a limit joint distribution $\sigma_0$ as $N \to \infty$. See section 2, item 3 for its precise formulation of $\sigma_0$. Here we introduce the $N \times N$ matrix liberation process starting at $\Xi(N)$ as the multi-matrix-valued process

$$t \mapsto \Xi^{lib}(N)(t) = \left(\Xi^{lib}_i(N)(t)\right)_{i=1}^{n+1} = \left((\xi_{ij}^{lib}(N)(t))_{j=1}^{r(i)}\right)_{i=1}^{n+1}$$

with

$$\xi_{ij}^{lib}(N)(t) := \left\{ \begin{array}{ll} U_N^{(i)}(t)\xi_{ij}(N)U_N^{(i)}(t)^* & (1 \leq i \leq n), \\ \xi_{n+1,j}(N) & (i = n+1). \end{array} \right.$$

We emphasize that the matrix liberation process $\Xi^{lib}(N)$ is new in random matrix theory and also that each $\Xi_i^{lib}(N)$ is a constant process in distribution, that is, its empirical distribution is independent of time, but the whole family $\Xi^{lib}(N)$ creates really non-commutative phenomena.

The concept of matrix liberation process comes from the liberation process in free probability defined as follows. Let $(M, \tau)$ be a tracial $W^*$-probability space, and $A_i \subset M$, $1 \leq i \leq n + 1$, be unital $*$-subalgebras (possibly to be $W^*$-subalgebras). Let $v_i$, $1 \leq i \leq n$, be $n$ freely independent, left free unitary Brownian motions $(\xi_{ij})_{i=1}^{n+1}$, which are ($*$-)freely independent of the $A_i$. Then the family consisting of $A_i(t) := v_i(t)A_i(v_i(t)^*)$, $1 \leq i \leq n$, and $A_{n+1}(t) := A_n(t)$ converges (in distribution or in moments) to a family of freely independent copies of $A_i$ as $t \to \infty$. Following Voiculescu [22], we call this ‘algebra-valued process’ $t \mapsto (A_i(t))_{i=1}^{n+1}$ the liberation process starting at $(A_i)_{i=1}^{n+1}$. The matrix liberation process $\Xi^{lib}(N)$ is a natural random matrix model of the liberation process. The attempt of investigating the matrix liberation process $\Xi^{lib}(N)$ is quite natural, because independent large random matrices are typical sources of free independence thanks to the celebrated work of Voiculescu [21] on one hand and because, on the other hand, the concept of free independence is central in free probability theory and the liberation process is a ‘stochastic interpolation’ between a given statistical relation and the freely independent one in the free probability framework.

The purpose of this article is to take a first step towards systematic study of the matrix liberation process $\Xi^{lib}(N)$ (rather than the unitary Brownian motions $U_N^{(i)}$) with the hope of providing a basis for the study of liberation process and free independence in view of random matrices. Here we take a large deviation phenomenon for its empirical distribution, say $\tau_{\Xi^{lib}(N)}$, (see section 2, item 2 for its formulation) as $N \to \infty$, and actually prove a large deviation upper bound in scale $1/N^2$ as $N \to \infty$. The reader may think that a possible approach is to obtain a large deviation upper bound for the $U_N^{(i)}$ at first and then to use the contraction principle. However, we do not employ such an approach, because we try to find the resulting formula of rate function in as direct a fashion as possible. In fact, the rate function that we will find is constructed by using a certain derivation that is similar to Voiculescu’s one in his liberation theory and shown to be good and to have a unique minimizer, which is identified with the empirical distribution $\sigma_0^{lib}$ of the liberation process starting at the distribution $\sigma_0$ (see section 2, item 3 for its precise formulation). Hence the standard Borel–Cantelli argument shows that $\tau_{\Xi^{lib}(N)} \to \sigma_0^{lib}$ in the topology of weak convergence uniformly on finite time intervals almost surely as $N \to \infty$. (See the end of the next section for several previously known related results.)

Let us take a closer look at the contents of this article. Section 2 is concerned with the framework to capture empirical distributions $\tau_{\Xi^{lib}(N)}$ and $\sigma_0^{lib}$ in terms of $C^*$-algebras. We emphasize that the $C^*$-algebra language is not avoidable if one wants to discuss the appropriate topology on the space of empirical distributions of non-commutative processes, because
$C^*$-algebras are only appropriate, non-commutative counterparts of the spaces of continuous functions over topological spaces. Hence section 2 is just a collection of formulations for several concepts, but important to understand this article.

We employ the strategy of the celebrated work on independent $N \times N$ self-adjoint Brownian motions due to Biane, Capitaine and Guionnet [3] (also see [7, part VI, section 18]). Namely, we use the exponential martingale of the martingale

$$t \mapsto \mathbb{E}[\text{tr}_N(P(\xi_{\text{lib}}^\tau(N)(\cdot))) \mid \mathcal{F}_t] - \mathbb{E}[\text{tr}_N(P(\xi_{\text{lib}}^\tau(N)(\cdot))))]$$

with $\text{tr}_N := \frac{1}{N} \text{Tr}_N$ for any self-adjoint non-commutative polynomial $P$ in indeterminates $x_{ij}(t)$, $1 \leq i \leq n+1$, $1 \leq j \leq r(i)$ and $t \geq 0$, where $P(\xi_{\text{lib}}^\tau(N)(\cdot))$ denotes the substitution of $\xi_{\text{lib}}^\tau(N)(t)$ for each $x_{ij}(t)$ into the polynomial $P$. Thus we need to compute the resulting exponential martingale by giving the explicit formula of the quadratic variation of the martingale (1). This is done in section 3 by utilizing the Clark–Ocone formula in Malliavin calculus. This is similar to \cite{3}, but we need some standard technology on SDEs in the framework of Malliavin calculus (e.g., \cite{16, chapter 2}). The key of section 3 is the introduction of a suitable non-commutative derivation, whose formula is not exactly same as but similar to the derivation in Voiculescu's (e.g., \cite{16, chapter 2}). The rest of the discussion goes along a standard strategy in the large deviation theory for hydrodynamics. Namely, we need to prove the exponential tightness of the probability measures in question, and introduce a suitable good rate function by looking at the quadratic variation computed in section 3. These together with proving the large deviation upper bound are done in section 5. In the same section we give a few important properties on the rate function including the fact that $\sigma_{\text{lib}}$ is its unique minimizer, and obtain the almost sure convergence of the empirical distribution $\tau_{\Xi(\text{lib})}$ as continuous processes. The final section 6 is a brief discussion on one of our on-going works in this direction.

2. Empirical distributions of (matrix) liberation processes

This section is devoted to a natural framework to capture the empirical distributions of (matrix) liberation processes.

Let $\mathbb{C}\langle x_{\cdot \circ}(\cdot) \rangle := \mathbb{C}\{x_{ij}(t)\}_{1 \leq j \leq r(i), 1 \leq i \leq n+1, t \geq 0}$ be the universal unital $*$-algebra with subject to $x_{ij}(t) = x_{ij}(0)^*$. We enlarge it to the universal enveloping $C^*$-algebra $C_R^\tau(\langle x_{\cdot \circ}(\cdot) \rangle)$ with subject to $\|x_{ij}(t)\| \leq R$. Let $TS(C_R^\tau(\langle x_{\cdot \circ}(\cdot) \rangle))$ be all the tracial states on $C_R^\tau(\langle x_{\cdot \circ}(\cdot) \rangle)$. We denote by $TS^c(C_R^\tau(\langle x_{\cdot \circ}(\cdot) \rangle))$ the set of $\tau \in TS(C_R^\tau(\langle x_{\cdot \circ}(\cdot) \rangle))$ such that

$$t \mapsto x_{ij}^\tau(t) := \pi_\tau(x_{ij}(t)) \in \pi_\tau((C_R^\tau(\langle x_{\cdot \circ}(\cdot) \rangle))') \cap \mathcal{H}_\tau$$

define strong-operator continuous processes, where $\pi_\tau : C_R^\tau(\langle x_{\cdot \circ}(\cdot) \rangle) \to B(\mathcal{H}_\tau)$ denotes the GNS representation associated with $\tau$ and the natural lifting of $\tau$ to $\pi_\tau((C_R^\tau(\langle x_{\cdot \circ}(\cdot) \rangle))')'$ (the closure in the strong-operator topology) in $\mathcal{H}_\tau$ is still denoted by the same symbol $\tau$.

Lemma 2.1. For any $\tau \in TS(C_R^\tau(\langle x_{\cdot \circ}(\cdot) \rangle))$ the following are equivalent:
(1) \( \tau \in TS^c(C^*_R(\{x_{\ast \ast}(\cdot)\})) \).

(2) For every \( \ell \in \mathbb{N} \) and any possible pairs \((i_1, j_1), \ldots, (i_\ell, j_\ell)\) the function
\[
(t_1, \ldots, t_\ell) \in [0, +\infty)^\ell \mapsto \tau(x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell)) \in \mathbb{C}
\]
is continuous.

**Proof.** (1) \( \Rightarrow \) (2) is trivial, since \( \|x_{ij}(t)\| \leq R \).

(2) \( \Rightarrow \) (1): For any monomial \( P = x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell) \) one has, by assumption,
\[
\|(x_{ij}^*(t) - x_{ij}^*(s))\Lambda_{\tau}(P)\|_{\mathcal{H}_\tau}^2
= \tau(x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell)x_{ij}^*(t_1) \cdots x_{ij}^*(t_\ell))
- \tau(x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell)x_{ij}(s)x_{ij}(s)x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell))
- \tau(x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell)x_{ij}(t_1) \cdots x_{ij}(t_\ell))
+ \tau(x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_1)x_{ij}(s)^2x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_1))
\to 0 \hspace{1cm} (\text{as } t \to s),
\]
where \( \Lambda_{\tau} : C^*_R(x_{\ast \ast}(\cdot)) \to \mathcal{H}_\tau \) denotes the canonical map. Since \( \|x_{ij}^*(t)\| \leq \|x_{ij}(t)\| \leq R \) as above, we conclude that \( t \mapsto x_{ij}^*(t) \) is strong-operator continuous. \( \square \)

Let \( \mathcal{W}_\ell \) be the words of length \( \ell \) in indeterminates \( x_{ij} = x_{i,j} \), \( 1 \leq i \leq n + 1 \), \( 1 \leq j \leq r(i) \). For each \( w \in \mathcal{W}_\ell \) we denote by \( w(t_1, \ldots, t_\ell) \) the substitution of \( x_{i_1,j_1}(t_1) \) for \( x_{i_1,j_1} \) into \( w = x_{i_1,j_1} \cdots x_{i_\ell,j_\ell} \). We introduce the function \( d : TS^c(C^*_R(x_{\ast \ast}(\cdot))) \times TS^c(C^*_R(x_{\ast \ast}(\cdot))) \to [0, +\infty) \) by
\[
d(\tau_1, \tau_2) := \sum_{m=1}^{\infty} \sum_{\ell=1}^{\infty} \frac{1}{2^m(2R)^\ell} \max_{w \in \mathcal{W}_\ell} \sup_{(t_1, \ldots, t_\ell) \in [0, m]^\ell} |\tau_1(w(t_1, \ldots, t_\ell)) - \tau_2(w(t_1, \ldots, t_\ell))|
\]
for \( \tau_1, \tau_2 \in TS^c(C^*_R(x_{\ast \ast}(\cdot))) \).

**Lemma 2.2.** (1) \( (TS^c(C^*_R(x_{\ast \ast}(\cdot))), d) \) is a complete metric space.

(2) For any sequence \( (\delta_k)_{k \geq 1} \) of positive real numbers,
\[
\Gamma(\delta_k) := \bigcap_{k \geq 1} \left\{ \tau \in TS^c(C^*_R(x_{\ast \ast}(\cdot))) \bigg| \sup_{0 \leq s \leq k} \max_{1 \leq I \leq r(i)} \tau((x_{ij}(s) - x_{ij}(t))^2)^{1/2} \leq \frac{1}{k} \right\}
\]
defines a compact subset in \( TS^c(C^*_R(x_{\ast \ast}(\cdot))) \) endowed with \( d \).

**Proof.** (1) It is easy to see that \( d \) defines a metric on \( TS^c(C^*_R(x_{\ast \ast}(\cdot))) \). Thus it suffices to confirm the completeness of the space.

Let \( \tau_p \in TS^c(C^*_R(x_{\ast \ast}(\cdot))) \) be a Cauchy sequence, that is, \( d(\tau_p, \tau_q) \to 0 \) as \( p, q \to \infty \). For every \( w = x_{i_1,j_1} \cdots x_{i_\ell,j_\ell} \in \mathcal{W}_\ell \) we have
\[
d(\tau_p(w(t_1, \ldots, t_\ell)) - \tau_q(w(t_1, \ldots, t_\ell))) \leq 2^{2m(2R)^\ell}d(\tau_p, \tau_q) \to 0
\]
as \( p, q \to \infty \) for every \( (t_1, \ldots, t_\ell) \in [0, m]^\ell \). Hence, \( \lim_{p, q \to \infty} \tau_p(x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell)) \) exists for every word \( x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell) \) in \( \mathbb{C}(x_{\ast \ast}(\cdot)) \). Since \( \mathbb{C}(x_{\ast \ast}(\cdot)) \) is the universal \( * \)-algebra generated by the \( x_{ij}(t) = x_{ij}(t)^* \), the words \( x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell) \) together with the unit 1 form a linear basis. Hence, we can construct a linear functional \( \tau \) on \( \mathbb{C}(x_{\ast \ast}(\cdot)) \) in such a way that \( \tau(1) = 1 \) and \( \tau(x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell)) = \lim_{p, q \to \infty} \tau_p(x_{i_1,j_1}(t_1) \cdots x_{i_\ell,j_\ell}(t_\ell)) \); hence \( \tau(P) = \lim_{p, q \to \infty} \tau_p(P) \) for every \( P \in \mathbb{C}(x_{ij}(\cdot)) \). Clearly, \( \tau \) is a tracial state. We have \( |\tau(P)| = \lim_{p, q \to \infty} |\tau_p(P)| \leq \|P\| \) for every \( P \in \mathbb{C}(x_{\ast \ast}(\cdot)) \) (\( \rightarrow C^*_R(x_{\ast \ast}(\cdot)) \) naturally), and therefore, \( \tau \) extends a tracial state on \( C^*_R(x_{\ast \ast}(\cdot)) \).
Fix \( w \in \mathcal{W}_t \) and \( m \in \mathbb{N} \) for a while. We have
\[
\left| \tau_p(w(t_1, \ldots, t_\ell)) - \tau(w(t_1, \ldots, t_\ell)) \right| \leq 2^m (2R)\ell \lim_{k' \to \infty} d(\tau_p, \tau_q).
\]
for every \( (t_1, \ldots, t_\ell) \in [0, m]^{\ell} \); hence
\[
\sup_{(t_1, \ldots, t_\ell) \in [0, m]^{\ell}} \left| \tau_p(w(t_1, \ldots, t_\ell)) - \tau(w(t_1, \ldots, t_\ell)) \right| \leq 2^m (2R)\ell \lim_{q \to \infty} d(\tau_p, \tau_q).
\]
Thus \( \tau(w(t_1, \ldots, t_\ell)) = \lim_{p \to \infty} \tau_p(w(t_1, \ldots, t_\ell)) \) is uniform in \( (t_1, \ldots, t_\ell) \in [0, m]^{\ell} \). Since \( m \in \mathbb{N} \) is arbitrary, we conclude, by Lemma 2.1, that \( \tau \in TS^c(C^*_R(\langle x_{\bullet} \rangle)) \).

(2) Let \( \tau_p \) be an arbitrary sequence in \( \Gamma(\delta_k) \). For every \( m = 1, 2, \ldots \) and every \( w \in \mathcal{W}_t \), the sequence of continuous functions \( \tau_p(w(t_1, \ldots, t_\ell)) \) is equicontinuous on \( [0, m]^{\ell} \), since
\[
\left| \tau_p(w(t_1, \ldots, t_\ell)) - \tau_p(w(t'_1, \ldots, t'_\ell)) \right| \leq R^{\ell-1} \sum_{m=1}^{\ell} \tau_p((x_{ij}(t_m) - x_{ij}(t'_m))^2)^{1/2}
\]
by the Cauchy–Schwarz inequality. Hence, for each \( m, \ell = 1, 2, \ldots \), the Arzela-Ascoli theorem (see e.g., [18, Theorem 11.28]) guarantees that any subsequence of \( \tau_p \) has a subsequence \( \tau_{p'} \) such that \( \tau_{p'}(w(t_1, \ldots, t_\ell)) \) converges uniformly on \( [0, m]^{\ell} \) as \( p' \to \infty \) for all \( w \in \mathcal{W}_t \) (n.b. \( \mathcal{W}_t \) is a finite set). Then, the usual diagonal argument with respect to \( \ell = 1, 2, \ldots \) enables us to select a subsequence \( \tau_{p''} \) in such a way that for every \( w \in \mathcal{W}_t \), \( \tau_{p''}(w(t_1, \ldots, t_\ell)) \) converges uniformly on \( [0, m]^{\ell} \) for as \( p'' \to \infty \). This is done for each \( m \) and any given subsequence of \( \tau_p \). Thus, by the usual diagonal argument again with respect to \( m \), we can choose a common subsequence \( \tau_{p'''} \) that satisfies the same uniform convergence for all \( m \). In the same way as in the discussion about (1) above we can construct a tracial state \( \tau \in TS^c(C^*_R(\langle x_{\bullet} \rangle)) \) in such a way that \( d(\tau_{p'''}, \tau) \to 0 \) as \( p'''' \to \infty \). Moreover, for every pair \( 0 \leq s, t \leq k \) with \( |s-t| \leq \delta_k \) and every possible pair \( (i, j) \), one has \( \tau((x_{ij}(s)-x_{ij}(t))^2) = \lim_{p'''' \to \infty} \tau_{p''''}((x_{ij}(s)-x_{ij}(t))^2) \leq 1/k^2 \), and hence \( \tau \) falls into \( \Gamma(\delta_k) \). □

We will provide some notations that will be used throughout the rest of this article.

1. **Time-marginal tracial states**: Let \( C^*_R(\langle x_{\bullet} \rangle) \) be the universal \( C^* \)-algebra generated by the \( x_{ij} \) for \( 1 \leq i \leq n+1, 1 \leq j \leq r \). For each \( t := (t_1, \ldots, t_{n+1}) \in [0, +\infty)^{n+1} \), there exists a unique \( * \)-homomorphism (actually a \( * \)-isomorphism) \( \pi_t : C^*_R(\langle x_{\bullet} \rangle) \to C^*_R(\langle x_{\bullet} \rangle) \) sending \( x_{ij} \) to \( x_{ij}(t_i) \). When \( t := t_1 = \cdots = t_{n+1} \) we simply write \( \pi_t := \pi_t(t) \). The \( \pi_t \) induces a continuous map \( \pi^*_t : TS^c(C^*_R(\langle x_{\bullet} \rangle)) \to TS^c(C^*_R(\langle x_{\bullet} \rangle)) \) by \( \pi^*_t(\tau) := \tau \circ \pi_t \), where \( TS^c(C^*_R(\langle x_{\bullet} \rangle)) \) is equipped with the \( w^* \)-topology. By Lemma 2.1 it is easy to see that \( t \mapsto \pi^*_t(\tau) \) is continuous for every \( \tau \in TS^c(C^*_R(\langle x_{\bullet} \rangle)) \). We call \( \pi^*_t(\tau) \) the **marginal tracial state** of \( \tau \) at multiple time \( t \).

2. **The empirical distribution** \( \tau_{\Xi^{lib}(N)} \) of \( \Xi^{lib}(N) \): The matrix liberation process \( \Xi^{lib}(N) \) defines \( \tau_{\Xi^{lib}(N)} \in TS^c(C^*_R(\langle x_{\bullet} \rangle)) \) in such a way that
\[
\tau_{\Xi^{lib}(N)}(P) := \text{tr}_N(P(\xi^{lib}(N))(\cdot)), \quad P \in \mathbb{C}(\langle x_{\bullet} \rangle).
\]
We call this tracial state \( \tau_{\Xi^{lib}(N)} \) the **empirical distribution** of the matrix liberation process \( \Xi^{lib}(N) \). The tracial state \( \tau_{\Xi^{lib}(N)} \) is a random tracial state; actually, it depends upon the \( n \) independent left unitary Brownian motions \( U^{(i)}_N \) via \( \xi^{lib}(N) \). Hence we have a Borel probability measure \( \mathbb{P}(\tau_{\Xi^{lib}(N)} \in \cdot) \) on \( TS^c(C^*_R(\langle x_{\bullet} \rangle)) \), and the large deviation upper bound that we will prove is about the sequence of probability measures \( \mathbb{P}(\tau_{\Xi^{lib}(N)} \in \cdot) \).
3. The empirical distribution $\sigma_0^{\text{lib}}$ of the liberation process with initial distribution $\sigma_0$: The limit joint distribution $\sigma_0$ of the sequence $\Xi(N)$ is defined to be a tracial state on $C_R^*(x_\bullet)$ naturally. Using its GNS construction and taking a suitable free product, we can construct self-adjoint random variables $x_{ij}^{\sigma_0} = x_{ij}^{\sigma_0*}$, $1 \leq i \leq n + 1$, $1 \leq j \leq r(i)$ and $n$ freely independent, left free unitary Brownian motions $v_i$, $1 \leq i \leq n$, in a tracial $W^*$-probability space, say $(\mathcal{L}, \sigma_0)$, in such a way that the joint distribution of the $x_{ij}^{\sigma_0}$ is indeed $\sigma_0$ and that the $x_{ij}^{\sigma_0}$ and the $v_i$ are freely independent. Thanks to the universality of the $C^*$-algebra $C_R^*(x_\bullet)$, the strong-operator continuous processes

$$x_{ij}^{\text{lib}}(t) := \begin{cases} v_i(t) x_{ij}^{\sigma_0} v_i(t)^* & (1 \leq i \leq n), \\ x_{n+i}^{\sigma_0} & (i = n + 1) \end{cases}$$

define a tracial state $\sigma_0^{\text{lib}} \in TS^c(C_R^*(x_\bullet))$.

Here is a simple fact.

**Proposition 2.3.** For every $P \in C(x_\bullet)$ we have $\lim_{N \rightarrow \infty} E[\tau_{\Xi_{\text{lib}}(N)}(P)] = \sigma_0^{\text{lib}}(P)$, that is, $\lim_{N \rightarrow \infty} E[\tau_{\Xi_{\text{lib}}(N)}(\cdot)] = \sigma_0^{\text{lib}}$ in the weak$^*$-topology.

**Proof.** The proof of [2, Theorem 1(2)] works well without essential change. \hfill $\square$

This essentially known fact should be understood as a counterpart of the convergence of finite dimensional distributions, and will be strengthened to the convergence as continuous processes in subsection 5.3. Namely, we will prove that the empirical distribution $\tau_{\Xi_{\text{lib}}(N)}$ itself converges to $\sigma_0^{\text{lib}}$ in the metric $d$ almost surely. Here, we briefly mention the known facts concerning the above proposition. The almost-sure version (i.e., without taking the expectation $E$) of the above proposition has also been known so far (see e.g., the introduction of [5]); in fact, one can see it in the same way as in [2, Theorem 1(2)] with the use of more recent results, for example, [12, Proposition 6.9] and (the proof of) [9, Theorem 4.3.5] (see the comment just before Example 4.3.7 there). Moreover, its almost-sure, strong convergence (i.e., the convergence of operator norms) version was recently established by Collins, Dahlqvist and Kemp [5]. In those results, the event of convergence (whose probability is of course 1) depends on the choice of time indices $t_1, \ldots, t_k$, unlike the fact that we will prove in subsection 5.3.

3. Computation of Exponential Martingale

It is easy to see that, as long as $i \neq n + 1$,

$$\langle \xi_{ij}^{\text{lib}}(N)(t), C_{\alpha\beta} \rangle_{\text{HS}} = \langle \xi_{ij}(N), C_{\alpha\beta} \rangle_{\text{HS}}$$

$$+ \sum_{\alpha', \beta' = 1}^N \int_0^t \left\langle i \left[ \frac{1}{\sqrt{N}} C_{\alpha' \beta'}, \xi_{ij}^{\text{lib}}(N)(s) \right], C_{\alpha\beta} \right\rangle_{\text{HS}} dB_{\alpha' \beta'}^{(ij)}(s)$$

$$+ \int_0^t \langle \text{tr}_N(\xi_{ij}^{\text{lib}}(N)(s))I_N - \xi_{ij}^{\text{lib}}(N)(s), C_{\alpha\beta} \rangle_{\text{HS}} ds$$

(2)

in the Euclidian coordinates on $M_N(\mathbb{C})^{\text{sa}}$ with respect to the basis $C_{\alpha\beta}$.

For a given $P = P^* \in C(x_\bullet)$ the matrix liberation process $t \mapsto \Xi_{\text{lib}}(N)(t)$ gives the (real-valued) bounded martingale $M_N$ in (1), that is,

$$M_N(t) = E[\tau_{\Xi_{\text{lib}}(N)}(P) \mid \mathcal{F}_t] - E[\tau_{\Xi_{\text{lib}}(N)}(P)].$$
The Clark–Ocone formula (see e.g., [10, Proposition 6.11] for any dimension and [16, subsection 1.3.4] for 1-dimension) asserts that

\[ M_N(t) = \sum_{k=1}^{n} \sum_{\alpha', \beta'=1}^{N} \int_{0}^{t} E[D_s^{(k; \alpha', \beta')} tr_N\left( P(\xi_{0}^{lib}(N)(\cdot)) \right) | \mathcal{F}_s] \, dB_{\alpha' \beta'}^{(k)}(s), \]

where \( D_s^{(k; \alpha', \beta')} \) denotes the Malliavin derivative in the Brownian motion \( B_{\alpha' \beta'}^{(k)} \) explained in [16, p.119]. The aim of this section is to compute this integrand explicitly by introducing a suitable non-commutative derivative.

Observe that all the coefficients of SDE (2) are independent of the time parameter and linear in the space variable. Thus, \( D_s^{(k; \alpha', \beta')} \langle \xi_{ij}^{lib}(N)(t), C_{\alpha \beta} \rangle_{HS} \) is well-defined. See e.g., [16, Theorem 2.2.1] for details. The function \( \xi \mapsto U_N^{(i)}(t)\xi U_N^{(i)}(t)^* \) is linear, and hence the matrix-valued process \( Y(t) \) in [16, p.126] is given by \( Y^{(\alpha, \beta)}(t) = \langle U_N^{(i)}(t)C_{\alpha \beta} U_N^{(i)}(t)^*, C_{\alpha \beta} \rangle_{HS} \). By (2), the formula [16, Eq.(2.59)] enables us to obtain that

\[
D_s^{(k; \alpha', \beta')} \langle \xi_{ij}^{lib}(N)(t), C_{\alpha \beta} \rangle_{HS} = \frac{1}{\sqrt{N}} \sum_{P=Q_k^{(i)}(t)Q_{2 \alpha \beta}} \sum_{s \leq t} \text{Re}(\xi_{ij}^{lib}(N)(s) U_N^{(i)}(s) U_N^{(i)}(t)^* C_{\alpha \beta} \langle Q_1 Q_2 \rangle_{HS}),
\]

where we used the convention of summation over repeated indices \( (\alpha_1, \beta_1), (\alpha_2, \beta_2) \) as in [16, section 2.2]. For a while, we assume that \( P \) is a monomial in the \( \xi_{ij}^{lib}(N)(t) \). By the Leibniz formula of \( D_s^{(k; \alpha', \beta')} \) we have, for any \( \zeta \in \mathbb{C} \),

\[
D_s^{(k; \alpha', \beta')} \text{Re}(\text{tr}_N(\zeta P(\xi_{0}^{lib}(N)(\cdot)))) = \frac{1}{\sqrt{N}} \sum_{P=Q_k^{(i)}(t)Q_{2 \alpha \beta}} \text{Re}(\text{tr}_N(Q_1 C_{\alpha \beta} Q_2) D_s^{(k; \alpha', \beta')} \langle \xi_{ij}^{lib}(N)(t), C_{\alpha \beta} \rangle_{HS})
\]

\[
= \frac{1}{\sqrt{N}} \sum_{P=Q_k^{(i)}(t)Q_2} \text{Re}(\text{tr}_N(Q_1 U_N^{(i)}(t) U_N^{(i)}(s)^* \xi_{ij}^{lib}(N)(s) U_N^{(i)}(s) U_N^{(i)}(t)^* Q_2))
\]

\[
= \text{Re}(\frac{\zeta i}{\sqrt{N}} \sum_{P=Q_k^{(i)}(t)Q_2} \text{tr}_N(U_N^{(i)}(s) \xi_{ij}(N), U_N^{(i)}(t)^* Q_2 Q_1 U_N^{(i)}(t))) \text{Re}(\zeta P(\xi_{0}^{lib}(N)(\cdot))))
\]

where we identify \( Q_l, l = 1, 2 \), with \( Q_l(\xi_{0}^{lib}(N)(\cdot)) \) for short. Here and below we used the convention that the summation \( \sum_{P=Q_k^{(i)}(t)Q_{2 \alpha \beta}} \) above means that the resulting sum becomes 0 if no \( P = Q_k^{(i)}(t) \) occurs. Therefore, we conclude that

\[
\sum_{k=1}^{n} \sum_{\alpha', \beta'=1}^{N} \int_{0}^{t} \frac{1}{\sqrt{N}} E[D_s^{(k; \alpha', \beta')} \text{Re}(\text{tr}_N(\zeta P(\xi_{0}^{lib}(N)(\cdot)))) | \mathcal{F}_s] \, dB_{\alpha' \beta'}^{(k)}(s)
\]

\[
= \sum_{k=1}^{n} \sum_{\alpha', \beta'=1}^{N} \int_{0}^{t} \frac{1}{\sqrt{N}} dB_{\alpha' \beta'}^{(k)}(s)
\]
Re(\text{tr}_N (\zeta U_N^{(k)}(s)E \left[ i \sum_{P=Q_1x_{ij}(t)Q_2}^{P \leq \lambda_{ij}(t)Q_2} [\xi_{kj}(N), U_N^{(k)}(t)^*Q_1U_N^{(k)}(t)] | \mathcal{F}_s \right] U_N^{(k)}(s)^*C_{\alpha\beta})).

Here, we have used the notation \(E[Y|\mathcal{F}_s] = [E[Y_s]|\mathcal{F}_s]\) for a matrix-valued random variable \(Y = [Y_{ij}]\), where we naturally extend \(E[-|\mathcal{F}_s]\) to complex-valued random variables. In the rest of this paper we also write \(E[Y] = [E[Y_s]]\).

We are now going back to a general \(P = P^* \in \mathbb{C}(\xi_{ij}(\cdot))\). Write \(P = \sum_i \zeta_i P_i\) with \(\zeta_i \in \mathbb{C}\) and monomials \(P_i\) in the \(\xi^{lib}_i(N)(t)\). Then we set

\[
Z_N^{(k)}(s) := \sum_i \zeta_i U_N^{(k)}(s)E \left[ i \sum_{P=Q_1x_{ij}(t)Q_2}^{P \leq \lambda_{ij}(t)Q_2} [\xi_{kj}(N), U_N^{(k)}(t)^*Q_1U_N^{(k)}(t)] | \mathcal{F}_s \right] U_N^{(k)}(s)^*
\]

which can be confirmed to be a self-adjoint matrix valued random variable thanks to \(P = P^*\). Since \(P = P^*\), that is, \(\text{tr}_N(P(\xi^{lib}_i(N)(\cdot)))\) is real-valued, we have

\[
M_N(t) = \sum_{k=1}^{n} \sum_{\alpha', \beta'=1}^{N} \int_0^t E[D_{\alpha'}^{(k;\alpha',\beta')} \text{Re}(\text{tr}_N(P(\xi^{(k;\alpha',\beta')(\cdot)))) | \mathcal{F}_s)] dB_{\alpha', \beta'}^{(k)}(s)
\]

and the quadratic variation \(\langle M_N \rangle\) of \(M_N(t)\) becomes

\[
\langle M_N \rangle(t) = \sum_{k=1}^{n} \sum_{\alpha', \beta'=1}^{N} \int_0^t \frac{1}{N} \text{tr}_N(Z_N^{(k)}(s)C_{\alpha', \beta'})^2 ds
\]

where we used a well-known formula on stochastic integrals (see e.g., [11, Proposition 3.2.17, Eq.(3.2.26)]) as well as \(\langle B_{\alpha\beta}^{(k)}(t), B_{\alpha', \beta'}^{(k)}(t) \rangle = \delta_{(k,\alpha,\beta),(k',\alpha',\beta')} t\) (see e.g., [11, Problem 2.5.5]).

Here we introduce suitable non-commutative derivations to describe \(Z_N^{(k)}(s)\).

**Definition 3.1.** We expand \(\mathbb{C}(\xi_{ij}(\cdot))\) into the universal \(*\)-algebra

\[
\mathbb{C}(\xi_{ij}(\cdot), v_*(\cdot)) := \mathbb{C}\{x_{ij}(t) \}_{1 \leq j \leq r(t), 1 \leq i \leq n+1, t \geq 0} \cup \{v_1(t) \}_{1 \leq i \leq n, t \geq 0}
\]

with subject to \(x_{ij}(t) = x_{ij}(t)^*\) and \(v_1(t)v_1(t)^* = 1 = v_1(t)^*v_1(t)\), and define the derivations

\[
\delta_{s}^{(k)} : \mathbb{C}(\xi_{ij}(\cdot), v_*(\cdot)) \rightarrow \mathbb{C}(\xi_{ij}(\cdot), v_*(\cdot)) \otimes \text{alg} \mathbb{C}(\xi_{ij}(\cdot), v_*(\cdot))
\]
by
\[
\delta_s^{(k)}_{x_{ij}}(t) = \delta_{k,i}1_{[0,t]}(s)(x_{kj}(t)v_k(t-s) \otimes v_k(t-s)^* - v_k(t-s) \otimes v_k(t-s)^* x_{kj}(t))
\]
for \(1 \leq k \leq n\). Let \(\theta : \mathbb{C}\langle x_{\bullet \circ} (\cdot), v_\bullet (\cdot) \rangle \otimes \mathbb{C}[x_{\circ \bullet} (\cdot), v_\bullet (\cdot) \rangle \rightarrow \mathbb{C}[x_{\bullet \circ} (\cdot), v_\bullet (\cdot) \rangle \) be a linear map defined by \(\theta(Q \otimes R) = RQ\), and define
\[
\mathcal{D}_s^{(k)} := \theta \circ \delta_s^{(k)} : \mathbb{C}[x_{\bullet \circ} (\cdot)] \rightarrow \mathbb{C}[x_{\bullet \circ} (\cdot), v_\bullet (\cdot) \rangle
\]
for \(1 \leq k \leq n\).

Although it is natural to define \(\mathcal{D}_s^{(k)}\) to be \(-i \theta \circ \delta_s^{(k)}\), we drop the scalar multiple \(-i\) in the definition for simplicity. It is easy to confirm that \(Z_N^{(k)}(s)\) admits the following formula
\[
Z_N^{(k)}(s) = \mathbb{E}\left[-i(\mathcal{D}_s^{(k)})P(\xi_{\bullet \circ}(N)(\cdot), U_N^{(\bullet)}(\cdot + s)U_N^{(\bullet)}(s)^*) \mid \mathcal{F}_s\right],
\]
and hence we have the next proposition thanks to [11, Corollary 3.5.13].

**Proposition 3.2.** For any \(P = P^* \in \mathbb{C}[x_{ij}(\cdot)]\), we have
\[
M_N(t) := \mathbb{E}\left[\tau_{\Xi \text{inh}(N)}(P) \mid \mathcal{F}_t\right] - \mathbb{E}\left[\tau_{\Xi \text{inh}(N)}(P)\right]
\]
\[
= \sum_{k=1}^n \sum_{\alpha', \beta' = 1}^N \int_0^t \text{tr}_N \mathbb{E}\left[-i(\mathcal{D}_s^{(k)})P(\xi_{\bullet \circ}(N)(\cdot), U_N^{(\bullet)}(\cdot + s)U_N^{(\bullet)}(s)^*) \mid \mathcal{F}_s\right] \, d\mathcal{B}_{\alpha' \beta'}(s) \frac{d\mathcal{B}_{\alpha' \beta'}(s)}{\sqrt{N}},
\]
\[
\langle M_N \rangle(t) = \frac{1}{N^2} \sum_{k=1}^n \int_0^t \left\| \mathbb{E}\left[(\mathcal{D}_s^{(k)})P(\xi_{\bullet \circ}(N)(\cdot), U_N^{(\bullet)}(\cdot + s)U_N^{(\bullet)}(s)^*) \mid \mathcal{F}_s\right] \right\|^2_{\text{tr}_N,2} \, ds.
\]

Therefore,
\[
\text{Exp}_N(t) := \exp \left(N^2 \left(\mathbb{E}\left[\tau_{\Xi \text{inh}(N)}(P) \mid \mathcal{F}_t\right] - \mathbb{E}\left[\tau_{\Xi \text{inh}(N)}(P)\right]\right) - \frac{1}{2} \sum_{k=1}^n \int_0^t \left\| \mathbb{E}\left[(\mathcal{D}_s^{(k)})P(\xi_{\bullet \circ}(N)(\cdot), U_N^{(\bullet)}(\cdot + s)U_N^{(\bullet)}(s)^*) \mid \mathcal{F}_s\right] \right\|^2_{\text{tr}_N,2} \, ds \right)
\]
becomes a martingale; hence \(\mathbb{E}[\text{Exp}_N(t)] = \mathbb{E}[\text{Exp}_N(0)] = 1\).

For the later use we remark that \(-i \mathcal{D}_s^{(k)} P\) is self-adjoint (since so is \(P\)), and hence
\[
\left| \mathbb{E}\left[(\mathcal{D}_s^{(k)})P(\xi_{\bullet \circ}(N)(\cdot), U_N^{(\bullet)}(\cdot + s)U_N^{(\bullet)}(s)^*) \mid \mathcal{F}_s\right] \right|^2_{\text{tr}_N,2}
\]
\[
= -\text{tr}_N \left( \mathbb{E}\left[(\mathcal{D}_s^{(k)})P(\xi_{\bullet \circ}(N)(\cdot), U_N^{(\bullet)}(\cdot + s)U_N^{(\bullet)}(s)^*) \mid \mathcal{F}_s\right] \right)^2.
\]

### 4. Convergence of Conditional Expectation

#### 4.1. Statement

For any given \(\tau \in TS^c(C_R^*(x_{\bullet \circ}(\cdot)))\) and any \(s \geq 0\) we will construct \(\tau^* \in TS^c(C_R^*(x_{\bullet \circ}(\cdot)))\) as follows. Taking a suitable free product, we expand \((\pi_\tau(C_R^*(x_{\bullet \circ}(\cdot))))\) to a sufficiently larger tracial W*-probability space, in which we can find \(n\) freely independent, left unitary free Brownian motions \(v_i^\tau, 1 \leq i \leq n\), that are freely independent of the \(x_{ij}^\tau(t), 1 \leq j \leq r(i), 1 \leq i \leq n + 1, 0 \leq t \leq s\) \((s \leq t\) if \(i \neq n + 1\)). Then we define new strong-operator continuous processes
\[
x_{ij}^\tau(t) := \begin{cases} v_i^\tau((t-s) \lor 0)x_{ij}^\tau(t \land s)v_i^\tau((t-s) \lor 0)^* & (1 \leq i \leq n), \\ x_{n+1}^\tau(t) & (i = n + 1). \end{cases}
\]
It is known that there exists a unique \(\tau\)-preserving conditional expectation \(E^*_\tau\) onto the von Neumann subalgebra generated by the \(x_{ij}^\tau(t) := x_{ij}^\tau(t)\), \(1 \leq i \leq n, 1 \leq j \leq r(i), 0 \leq t \leq s\),
and the $x_{n+1,j}^\tau(t) = x_{n+1,j}^\tau(t)$, $1 \leq j \leq r(n + 1)$, $t \geq 0$, in the ambient tracial $W^*$-probability space. Via the $*$-homomorphism sending $x_{ij}(t)$ to $x_{ij}^\tau(t)$, we obtain the desired tracial state $\tau^* \in TS^*(C_R(x_\bullet(\cdot)))$.

To each event $\mathcal{E}$, we associate the essential-supremum norm relative to $\mathcal{E}$:

$$\|X\|_\mathcal{E} := \inf \{ L > 0 \mid P(\mathcal{E} \cap \{|X| > L\}) = 0 \}$$

for every random variable $X$. Here is the main assertion of this section.

**Theorem 4.1.** For any $\tau \in TS^*(C_R(x_\bullet(\cdot)))$ and $P_1, \ldots, P_m \in \mathbb{C}(x_\bullet(\cdot), v_\bullet(\cdot))$ we have

$$\lim_{\varepsilon \downarrow 0} \lim_{N \to \infty} \sup_{s \geq 0} \| \text{tr}_N(\mathbb{E}[P_{1,N}^\tau | \mathcal{F}_s] \cdots \mathbb{E}[P_{m,N}^\tau | \mathcal{F}_s]) - \tau(E_{\tau^*}(P_{1,N}^\tau) \cdots E_{\tau^*}(P_{m,N}^\tau)) \|_{\mathcal{O}_\tau(\tau)} = 0$$

with

$$P_{k,N}^\tau := P_k(x^{\text{lib}}_\bullet(N)(), U_N^{(\bullet)}(\cdot) \vee s)U_N^{(\bullet)}(s)^*, \quad P_{k,N}^\tau^* := P_k(x^{\tau*}_\bullet(\cdot), v^{\tau*}_\bullet((\cdot - s) \vee 0))$$

for $1 \leq k \leq m$ and with $\mathcal{O}_\tau(\tau) := \{ d(\tau^{\text{lib}}(N), \tau) < \varepsilon \}$, an event. Here we use the same convention such as $\mathbb{E}[P_{k,N} | \mathcal{F}_s]$ as in section 2.

By definition, $\mathcal{D}_s^{(k)} P$ with $P \in \mathbb{C}(x_\bullet(\cdot))$ is a linear combination of monomials of the form $1_{[0,1]}(s) v_k(t - s)^* Q v_k(t - s)$ with fixed $Q \in \mathbb{C}(x_\bullet(\cdot))$ and $t \geq 0$. Hence the next corollary immediately follows from Theorem 4.1.

**Corollary 4.2.** For any $\tau \in TS^*(C^*(x_\bullet(\cdot)))$ and $P \in \mathbb{C}(x_\bullet(\cdot))$ we have

$$\lim_{\varepsilon \downarrow 0} \lim_{N \to \infty} \sup_{s \geq 0} \| \text{tr}_N(\mathbb{E}[\mathcal{D}_s^{(k)} P(x^{\text{lib}}_\bullet(N)(), U_N^{(\bullet)}(\cdot) \vee s)U_N^{(\bullet)}(s)^*) | \mathcal{F}_s]) - \tau(E_{\tau^*}((\mathcal{D}_s^{(k)} P(x^{\tau*}_\bullet(\cdot), v^{\tau*}_\bullet((\cdot - s) \vee 0)))^2) \|_{\mathcal{O}_\tau(\tau)} = 0$$

for every $1 \leq k \leq n$.

### 4.2. Proof of Theorem 4.1.

The proof is divided into two steps; we first prove in subsection 4.2.1 that

$$\lim_{\varepsilon \downarrow 0} \lim_{N \to \infty} \| \text{tr}_N(\mathbb{E}[P_{1,N}^\tau | \mathcal{F}_s] \cdots \mathbb{E}[P_{m,N}^\tau | \mathcal{F}_s]) - \tau(E_{\tau^*}(P_{1,N}^\tau) \cdots E_{\tau^*}(P_{m,N}^\tau)) \|_{\mathcal{O}_\tau(\tau)} = 0$$

for each fixed $s \geq 0$, and then in subsection 4.2.2 that the convergence is actually uniform in time $s$. This strategy is motivated by Lévy’s work [13], and indeed his method is crucial in subsection 4.2.2. A slight generalization of what Lévy established in [13] is necessary, and thus we will explain it in subsection 4.3 for the reader’s convenience.

Note that all the $P_k$ is ‘supported’ in a finite time interval $[0, T]$, that is, the letters appearing in those $P_k$ are from the $x_{ij}(t)$ and $v_i(t)$ with $t \leq T$. Note also that we may and do assume that all the given $P_k$ are monomials.

#### 4.2.1. Convergence at each time $s$.

Choose another independent $n$-tuple $V_{N}^{(i)}$ of $N \times N$ left unitary Brownian motions that are independent of the original $n$-tuple $U_{N}^{(i)}$. Denote by $\mathbb{E}_V$ the expectation only in the stochastic processes $V_{N}^{(i)}$. Define

$$\xi^{\text{lib}}_{ij}(N)^V_s(t) := \begin{cases} V_{N}^{(i)}((t - s) \vee 0) \xi^{\text{lib}}_{ij}(N)((t - s) \wedge N) \xi^{(i)}_{N}((t - s) \vee 0)^* & (1 \leq i \leq n), \\ \xi^{\text{lib}}_{n+1,j}(N)^V(t) = \xi^{\text{lib}}_{n+1,j}(N) & (i = n + 1). \end{cases}$$

Then it is not hard to see that

$$\mathbb{E}[P_{k,N}^\tau | \mathcal{F}_s] = \mathbb{E}_V[P_k(x^{\text{lib}}_\bullet(N)^V(\cdot), V_{N}^{(i)}((\cdot - s) \vee 0))]$$
due to the left increment property of left unitary Brownian motions.

Note that $P_{k,s,N}^t := P_k(\xi_{ij}^l(N)(t), V_N^*(l - s) \lor 0)$ depends only on a finite number of $V_N^{(i)}(t)$ because we have fixed $s$. Each of those $V_N^{(i)}(t)$ is written as

$$V_N^{(i)}(t) = W_N^{(i,k)}(t - (k/3))W_N^{(i,k-1)}(1/3) \cdots W_N^{(i,0)}(1/3) \lor W_N^{(i,0)}(t)$$

with $W_N^{(i,0)}(t) := V_N^{(i)}(t + (l/3))V_N^{(i)}(l/3)^*$, $0 \leq t \leq 1/3$. Note that those $W_N^{(i,0)}(t)$ ($0 \leq t \leq 1/3$) become independent, $N \times N$ left unitary Brownian motions. In this way, we may think of $P_{k,s,N}^t$ as a monomial in some $\xi_{ij}^l(N)(t)$ (with $t \leq s$ as long as $i \neq n + 1$) and some $W_N^{(i,0)}(t), W_N^{(i,0)}(t)^*$ with $0 \leq t \leq 1/3$. Accordingly, we write $w_{i,l}(t) := v_{i,l}(t + (l/3))v_{i,l}(l/3)^*$, $0 \leq l \leq 1/3$, $l \in \mathbb{N}$, which become left free unitary Brownian motions. Then $P_k^* = P_k(x_t^l(\cdot), v_{i,l}^*((\cdot - s) \lor 0))$ is also the same monomial as $P_{k,s,N}^t$ with the substitution of $x_{i,l}^*(t)$ and $w_{i,l}(t)$ for $\xi_{ij}^l(N)(t)$ and $W_N^{(i,0)}(t)$, respectively. Consequently, it suffices, for the purpose here, to prove that

$$\lim_{\epsilon \searrow 0} \lim_{N \to \infty} \left\| \text{tr}_N \left( \mathbb{E}_W[Q_{1,N}] \cdots \mathbb{E}_W[Q_{m,N}] \right) - \tau(E_1^*(Q_1^t) \cdots E_m^*(Q_m^t)) \right\|_{\mathcal{O}(\tau)} = 0 \quad (4)$$

with

$$Q_{k,N} := Q_k(\xi_{ij}^l(N)(\cdot), W_N^{(i,o)}(\cdot)), \quad Q_k^t := Q_k(x_{t,l}^l(\cdot), w_{i,l}^*(\cdot)), \quad 1 \leq k \leq m$$

for any given monomials $Q_{1,N}, \ldots, Q_{m,N}$ in indeterminates $x_{i,j}(t)$ (with $0 \leq t \leq s$ as long as $i \neq n + 1$, $w_{i,l}(t), w_{i,l}(t)^*$ with $0 < t \leq 1/3$, where $\mathbb{E}_W$ denotes the expectation only in the stochastic processes $W_N^{(i,0)}$ and also $Q_{k,N}$ and $Q_k^t$ are defined similarly as above.

Note that the given monomials $Q_{1,N}, \ldots, Q_{m,N}$ depend only on a finite number of indeterminates $x_{i,j}(t_1), \ldots, x_{i,j}(t_p), x_{i,j}(t_{p+1}), \ldots, x_{i,j}(t_{p'})$ (with $1 \leq t_1, \ldots, t_p \leq n$, $0 \leq t_1, \ldots, t_p \leq s$) and $w_{i,l}(t_1), \ldots, w_{i,l}(t_q)$ (with $0 \leq t_1, \ldots, t_q \leq 1/3$). As in [5, section 4] we may and do write $w_{i,l}(t_k) = f_k(g_{i,l}(k))$, where $f_k$ is a continuous function from the real line $\mathbb{R}$ to the 1-dimensional torus $\mathbb{T}$ (depending only on the time $t_k$) and a standard semicircular system $g_{i,l,k}, \ldots, g_{i,l,q}$, which is freely independent of $x_{i,j}(t_1), \ldots, x_{i,j}(t_p)$ and $x_{i,j}(t_{p+1}), \ldots, x_{i,j}(t_{p'})$. Accordingly, by [5, Proposition 4.3] we can choose an independent family of $N \times N$ standard Gaussian self-adjoint random matrices $G_{i,j}^{(1)}, \ldots, G_{i,j}^{(1)}$ in such a way that they are independent of the $U^{(i)}(t_1), \ldots, U^{(i)}(t_p)$ (corresponding to indeterminates $x_{i,j}(t_1), \ldots, x_{i,j}(t_p)$) and the operator norm $\|W_N^{(i,0)}(t_k) - f_k(G_{i,j}(t_k))\|_{\mathcal{O}(\tau)} \to 0$ almost surely as $N \to \infty$. For any $x, y \in \mathbb{C}^N$ with $\|x\|_{\mathbb{C}^N} \leq 1$, $\|y\|_{\mathbb{C}^N} \leq 1$, we have

$$\left\| \left( \mathbb{E}_W[Q_k(\xi_{ij}^l(N)(\cdot), W_N^{(i,o)}(\cdot))] - \mathbb{E}_G[Q_k(\xi_{ij}^l(N)(\cdot), f(\cdot)(G_N^{(i,o)}(\cdot)))] \right) x, y \right\|_{\mathbb{C}^N}$$

$$= \left\| \mathbb{E}_{W \cup G}[\xi_{ij}^l(N)(\cdot), W_N^{(i,o)}(\cdot)] - \mathbb{E}_{W \cup G}[\xi_{ij}^l(N)(\cdot), f(\cdot)(G_N^{(i,o)}(\cdot))] \right\|_{\mathbb{C}^N}$$

$$\leq \mathbb{E}_{W \cup G}[\left\| (\mathbb{E}_W[\xi_{ij}^l(N)(\cdot), W_N^{(i,o)}(\cdot)] - \mathbb{E}_G[\xi_{ij}^l(N)(\cdot), f(\cdot)(G_N^{(i,o)}(\cdot))] \right\|_{\mathbb{C}^N}]$$

$$\leq \mathbb{E}_{W \cup G}[\left\| Q_k(\xi_{ij}^l(N)(\cdot), W_N^{(i,o)}(\cdot)) - Q_k(\xi_{ij}^l(\cdot), f(\cdot)(G^{(i,o)}(\cdot))) \right\|_{\mathbb{C}^N}]$$

with the expectations $\mathbb{E}_G$ and $\mathbb{E}_{W \cup G}$ only in the variables $G_N^{(i,1)}$ and the $W_N^{(i,0)}(t), G_N^{(i,1)}$, respectively. Hence we conclude that

$$\left\| \mathbb{E}_W[Q_k(\xi_{ij}^l(N)(\cdot), W_N^{(i,o)}(\cdot))] - \mathbb{E}_G[Q_k(\xi_{ij}^l(N)(\cdot), f(\cdot)(G_N^{(i,o)}(\cdot)))] \right\|_{\mathbb{C}^N}$$

$$\leq \mathbb{E}_{W \cup G}[\left\| Q_k(\xi_{ij}^l(N)(\cdot), W_N^{(i,o)}(\cdot)) - Q_k(\xi_{ij}^l(\cdot), f(\cdot)(G^{(i,o)}(\cdot))) \right\|_{\mathbb{C}^N}]$$

$$\to 0$$

as $N \to \infty$. Therefore, we complete the proof of (4).
where \(\|\xi(t)\|_{\infty} \leq R\) and since all the \(W_N^{(t_i, t_k)}(t)\) and \(f_t(G_N^{(t_i, t_k)}(t))\) are unitary matrices. Since \(\max_{1 \leq k \leq p} \|W_N^{(t_i, t_k)}(t) - f_{t_k}(G_N^{(t_i, t_k)}(t))\|_{M_N(\mathbb{C})} \to 0\) almost surely as \(N \to \infty\), we conclude that

\[
\lim_{N \to \infty} \left\| \text{tr}_N \left[ E_W[Q_1, N] \cdots E_W[Q_m, N] \right] - \text{tr}_N \left[ E_W[G_N^{(t_i, t_k)}(t)] \cdots E_W[G_N^{(t_i, t_k)}(t)] \right] \right\| = 0
\]

with

\[
Q_k^{(t_i, t_k)} := Q_k(\xi(t_i, t_k)), \quad 1 \leq k \leq m.
\]

Consider the event

\[
\mathcal{E}_N := \bigcap_{k=1}^q \left\{ \|G_N^{(t_i, t_k)}(t)\|_{M_N(\mathbb{C})} \leq 3 \right\},
\]

whose probability \(\mathbb{P}(\mathcal{E}_N)\) is known to converge to 1 as \(N \to \infty\) (see e.g., [1, subsection 5.5] and references therein). Similarly as above we can find a universal constant \(C' > 0\) so that

\[
\left| \text{tr}_N \left[ E_G \left[ 1_{\mathcal{E}_N} Q_1^{(t_i, t_k)}(t) \right] \cdots E_G \left[ 1_{\mathcal{E}_N} Q_m^{(t_i, t_k)}(t) \right] \right] - \text{tr}_N \left[ E_G \left[ 1_{\mathcal{E}_N} Q_{p_1}^{(p_1)}(t) \right] \cdots E_G \left[ 1_{\mathcal{E}_N} Q_{p_m}^{(p_m)}(t) \right] \right] \right| \leq C' \delta
\]

with

\[
Q_k^{(p_1, p_m)} := Q_k(\xi(p_1, p_m)(t_i, t_k)), \quad 1 \leq k \leq m.
\]

since \(\|f_{t_k}(G_N^{(t_i, t_k)}) - p_{t_k}(G_N^{(t_i, t_k)})\|_{M_N(\mathbb{C})} \leq \delta\) on the event \(\mathcal{E}_N\). By the 'Cauchy–Schwarz inequality' for matricial expectations (see Remark 4.5 below), we have

\[
\left\| E_G \left[ 1_{\Omega \subset \mathcal{E}_N} Q_k^{(p_1, p_m)}(t) \right] \right\|_{M_N(\mathbb{C})} \leq \left( 1 - \mathbb{P}(\mathcal{E}_N) \right)^{1/2} \left\| E_G \left[ (Q_k^{(p_1, p_m)}(t))^* Q_k^{(p_1, p_m)}(t) \right] \right\|_{M_N(\mathbb{C})}^{1/2}
\]

where \(\| - \|_{\infty}\) denotes the essential-supremum norm.

For a given \(0 < \delta \leq 1\), the Weierstrass theorem enables us to choose a polynomial \(p_{t_k}\) so that the supremum norm \(\|p_{t_k} - f_{t_k}\|_{-3, 3}\) over the interval \([-3, 3]\) is not greater than \(\delta\). For a while, we fix such polynomials \(p_{t_k}\), \(1 \leq k \leq q\). Since \(w_k^{(t_i, t_k)}(t_k) = f_{t_k}(g_k(t_k))\) and \(\|g_k(t_k)\| \leq 2\), it immediately follows that there exists a positive constant \(C > 0\) such that

\[
\left| \tau(E^{(t_i, t_k)}_1 \cdots E^{(t_i, t_k)}_m) - \tau(E^{(p_1, p_1)}_1 \cdots E^{(p_1, p_1)}_m) \right| \leq C \delta
\]

with

\[
Q_k^{(p_1, p_1)} := Q_k(\xi(\cdot, \cdot)(p_1, p_1)(t_i, t_k)), \quad 1 \leq k \leq m.
\]
with some constant $C'_k > 0$ depending only on $k$, since the $f_k(G_N^{(i_k,l_k)})$ are unitary matrices and $\|e_{ij}^{(\text{le})}((N)/(t))\|_{M_N(\mathbb{C})} \leq R$. Since $\mathbb{P}(E_N) \to 1$ as $N \to \infty$ as remarked before, we need to prove that

$$\sup_{N \in \mathbb{N}} \max_{1 \leq k \leq m} \left\| E_G \left[ (Q_{k,N}^{(p_1(G_1^\ast)))^\ast Q_{k,N}^{(p_2(G_2^\ast)))} \right] \right\|_{M_N(\mathbb{C})} < +\infty \quad (10)$$

and

$$\lim_{\epsilon \to 0} \lim_{N \to \infty} \left\| tr_N \left( tr_N \left( E_G \left[ Q_{1,N}^{(p_1(G_1^\ast))) \ast} \cdots \ast E_G \left[ Q_{m,N}^{(p_m(G_m^\ast)))} \right] \right) \right) \right\|_{Q_{\epsilon}(\tau)} = 0, \quad (11)$$

both of which are similar to what Biane, Capitaine and Guionnet proved in [3, section 4]. However, we will give more 'exact' proofs to them later for the sake of completeness. In fact, (8) and (10) imply that

$$\lim_{N \to \infty} \left\| E_G \left[ 1_{\Omega} \chi_N \right] Q_{k,N}^{(p_1(G_1^\ast)))^\ast Q_{k,N}^{(p_2(G_2^\ast)))} \right\|_{M_N(\mathbb{C})} = 0, \quad 1 \leq k \leq m, \quad (12)$$

and moreover, by (9)

$$\lim_{N \to \infty} \left\| E_G \left[ 1_{\Omega} \chi_N \right] Q_{k,N}^{(f_k(G_k^\ast)))^\ast Q_{k,N}^{(f_k(G_k^\ast)))} \right\|_{M_N(\mathbb{C})} = 0, \quad 1 \leq k \leq m. \quad (13)$$

Remark that $\| 1_{\chi_N} P_{t_k}(G_N^{(i_k,l_k)}) \|_{M_N(\mathbb{C})} \leq \| P_{t_k} \|_{[-3,3]} \leq 1 + \delta \leq 2$. By (5)–(7) and (11)–(13), we have

$$\lim_{\epsilon \to 0} \lim_{N \to \infty} \left\| tr_N \left( E_{W} \left[ Q_{1,N} \right] \cdots \ast E_{W} \left[ Q_{m,N} \right] \right) \right\|_{Q_{\epsilon}(\tau)} \leq (C' + C)\delta.$$

Hence (4) follows because $\delta > 0$ can arbitrarily be small and both $C, C'$ are independent of the choice of $\delta > 0$. Hence we have completed the first step expect showing (10) and (11).

Here, we prove (10) and (11). We need two simple lemmas, which are of independent interest because they are very explicit.

**Lemma 4.3.** Let $G^{(i)}$ be an independent sequence of $N \times N$ standard Gaussian self-adjoint random matrices, and $A^{(i)}$ be an sequence of $N \times N$ deterministic matrices. Then we have

$$E \left[ G^{(p_1)} \ast A^{(q_1)} \cdots \ast A^{(q_{(\ell-1)})} \ast G^{(p_{\ell})} \right] = \sum_{\pi \in \mathcal{P}_\pi^\ell} N^{\sharp(\gamma_{\pi^-})-1/2} \left( tr_{\gamma_{\pi}} \left[ A^{(q_1)}, \ldots, A^{(q_{(\ell-1)})} \right] \right),$$

Here, $\mathcal{P}_\pi^\ell(\ell)$ is the set of all permutations $\pi$ with $p \circ \pi = p$ whose cycle decompositions consist only of transpositions, $\gamma_{\ell}$ denotes $(1,2,\ldots,\ell)$, $\sharp(\pi_{\gamma_{\ell}})$ is the number of cycles in $\pi_{\gamma_{\ell}}$, and finally
\[
\text{tr}_\sigma[A^{(q(1))}, \ldots, A^{(q(\ell-1))}, *], \quad \sigma \in \mathcal{G}_\ell, \text{ is defined as follows. If } \sigma \text{ is a cycle } (i_1, \ldots, i_k), \text{ then it becomes}
\]
\[
\begin{cases}
\text{tr}_N(A^{(q(i_1))}, \ldots, A^{(q(i_k))})I_N & (i_1, \ldots, i_k \leq \ell - 1), \\
A^{(q(i_{j+1}))} \ldots A^{(q(i_k))}A^{(q(i_1))} \ldots A^{(q(i_{j-1}))} & (i_j = \ell), \\
I_N & (k = 1, i_1 = \ell),
\end{cases}
\]
and generally it is to be
\[
\text{tr}_{\sigma_1}[A^{(q(1))}, \ldots, A^{(q(\ell-1))}, *] \cdots \text{tr}_{\sigma_m}[A^{(q(1))}, \ldots, A^{(q(\ell-1))}, *]
\]
with cycle decomposition \(\sigma = \sigma_1 \cdots \sigma_m\) (n.b., only one cycle \(\sigma_k\) contains \(\ell\); hence no ambiguity occurs in the above product because its factors commute with each other).

Note that \(\text{tr}_N(\text{tr}_\sigma[A_1, \ldots, A_{\ell-1}, *]A_\ell) = \text{tr}_\sigma[A_1, \ldots, A_{\ell-1}, A_\ell]\) with the notation of [15, Proposition 22.32] on the right-hand side. This is the key of the proof below.

**Proof.** Remark that \(\text{tr}_N(XA) = \text{tr}_N(\mathbb{E}[G^{(p(1))} A^{(q(1))} \cdots A^{(q(\ell-1))} G^{(p(\ell))})A]\) for all \(A\) forces \(X = \mathbb{E}[G^{(p(1))} A^{(q(1))} \cdots A^{(q(\ell-1))} G^{(p(\ell))}]\). This together with [15, Proposition 22.32] (see the above remark) implies the desired result. \(\square\)

This lemma immediately implies (10), because \(\|\xi_{ij}^{\text{lib}}(N)(t)\|_{M_\mathbb{C}} \leq R\) and \(\sharp(\gamma_{\ell_k} - 1 - \ell_k/2) \leq 0\), see e.g., [15, Exercise 22.15].

Similarly as above we derive the next lemma from [15, Proposition 22.33] and its discussion there.

**Lemma 4.4.** Let \((\mathcal{M}, \tau)\) be a tracial \(W^\ast\)-probability space. Let \(g_i\) be an freely independent sequence of standard semicircular elements in \((\mathcal{M}, \tau)\), and \(a_i\) be an sequence of elements in \(\mathcal{M}\) which are freely independent of the \(g_i\). Let \(E\) be a unique \(\tau\)-preserving conditional expectation onto the von Neumann subalgebra generated by the \(a_i\). Then we have
\[
E(g_{p(1)}a_{q(1)} \cdots a_{q(\ell-1)}g_{p(\ell)}) = \sum_{\pi \in NC_2^p(\ell)} \tau_{\pi \gamma_\ell}[a_{q(1)}, \ldots, a_{q(\ell-1)}, *],
\]
where \(NC_2^p(\ell)\) is the subset of all \(\pi \in P_2^p(\ell)\) that are non-crossing as partitions. The other undefined symbol \(\tau_{\pi \gamma_\ell}[a_{q(1)}, \ldots, a_{q(\ell-1)}, *]\) is similarly defined as in the previous lemma.

It is not so hard to derive (11) from Lemmas 4.3, 4.4 in the following way: For simplicity we write
\[
Q_k^{G_{i,j}}(\tau_{\pi \gamma_\ell}) = A_k^{(q(0))}G_k^{(p(1))}A_k^{(q(1))} \cdots A_k^{(q(\ell_k - 1))}G_k^{(p(\ell_k))}A_k^{(q(\ell_k))},
\]
where each \(G_k^{(p(i))}\) (or \(A_k^{(q(i))}\)) is some of the \(G_N^{(i,j)}\) (resp. a product of some \(\xi_{ij}^{\text{lib}}(N)(t)\) (t \(\leq s\) as long as \(i \neq n + 1\) or \(I_N\)) and accordingly, each \(g_{p(i)}^{(k)}\) (or \(a_{q(i)}^{(k)}\)) is some of the \(g_i\) (resp. a product of some \(x_i\) (t \(\leq s\) as long as \(i \neq n + 1\) or 1). Remark that \(\sharp(\gamma_{\ell_k} - 1 - \ell_k/2)\) is always non-positive and equals 0 if and only if \(\pi\) is non-crossing, see e.g., [15, Exercise 22.15]. Hence, by Lemmas 4.3 and 4.4 we have
\[
\mathbb{E}_G[Q_k^{G_{i,j}}] = \sum_{\pi \in NC_2^p(\ell_k)} A_k^{(q(0))}\text{tr}_{\pi \gamma_\ell}[A_k^{(q(1))}, \ldots, A_k^{(q(\ell_k - 1))}, *] A_k^{(q(\ell_k))} + \sum_{\pi \in P_2^p(\ell_k) \backslash NC_2^p(\ell_k)} \mathbb{E}_G[A_k^{(q(0))}, \text{tr}_{\pi \gamma_\ell}[A_k^{(q(1))}, \ldots, A_k^{(q(\ell_k - 1))}, *] A_k^{(q(\ell_k))}].
\]
The convergence is uniform in time $s$.

For a while, we are dealing with an arbitrarily fixed monomial $P$ whose letters are supported in $[0, T]$, that is, the letters are from the $x_{ij}(t)$ and the $v_i(t)$ with $t \leq T$, and so is $\Pi_s P$. As before we have
\[
E\left[ P\left( \xi^{lib}_N(\cdot), U_N(\cdot \vee s)U_N(\cdot)\right) \mid \mathcal{F}_s \right] = E_V \left[ \langle \Pi_s P(\xi^{lib}_N(\cdot), V_N(\cdot)) \rangle \right].
\]
where $V^{(i)}_N$, $1 \leq i \leq n$, are $n$ independent left unitary Brownian motions that are independent of the $U^{(i)}_N(t)$ with $t \leq s$. Denote by $L(P)$ the number of letters in the given monomial $P$ (we call it the length of $P$). Observe that $L(\Pi_s P) \leq 3L(P)$.

In what follows, we fix $s$, but will give our desired estimate in such a way that it is independent of the choice of $s$.

Let us introduce the following algorithm: If $v_i(t_1), v_i(t_2), \ldots, v_i(t_{\ell_i})$ with $t_1 < t_2 < \cdots < t_{\ell_i}$ (n.b., $\ell_i \leq \sum_{i=1}^n \ell_i = L(\Pi_s P) \leq 3L(P)$) are all the $v_i(\cdot)$ letters appearing in $\Pi_s P$, we replace these with

$$w_{i1}, w_{i2}w_{i1}, w_{i3}w_{i2}w_{i1}, \ldots, w_{i\ell_i} \cdots w_{i2}w_{i1}$$

with new indeterminates $w_{ij}$ ($1 \leq i \leq n$, $1 \leq j \leq \ell_i$ ($\leq 3L(P)$)), and set $t_{ij} := t_j - t_{j-1}$ with $t_0 := 0$. Applying this algorithm to the monomial $\Pi_s P$, we get a new monomial $\hat{\Pi}_s P$ whose letters are in the $x_{ij}(t)$ ($0 \leq t \leq s$) and the $w_{ij}$. Observe the following rather rough estimates

$$L(\hat{\Pi}_s P) \leq L(\Pi_s P)^2 \leq 9L(P)^2, \quad t_{ij} \leq T. \quad (14)$$

Let $W^{(i,j)}_N$ be independent left unitary Brownian motions that are independent of the $U^{(i)}_N(t)$ with $t \leq s$ and denote by $E_W$ the expectation only in the stochastic processes $W^{(i,j)}_N$. By the left increment property of left unitary Brownian motions we have

$$E\left[P(\xi^{lib}_N(\cdot), U^{(i)}_N(\cdot) \vee s)U^{(i)}_N(s) \right | F_s] = E_W \left[(\Pi_s P)(\xi^{lib}_N(\cdot), V^{(i)}_N(\cdot)) \right]$$

$$= E_W \left[(\hat{\Pi}_s P)(\xi^{lib}_N(\cdot), W^{(i)}_N(t_{ij})) \right],$$

where $(\hat{\Pi}_s P)(\xi^{lib}_N(\cdot), W^{(i)}_N(t_{ij}))$ denotes the substitution of $\xi^{lib}_N(t)$ and $W^{(i,j)}_N(t_{ij})$ for $x_{ij}(t)$ and $w_{ij}$, respectively, into $\hat{\Pi}_s P$.

For simplicity, let us denote $X := \hat{\Pi}_s P$, and write $X = X(1) \cdots X(\ell)$ with $\ell := L(X)$ whose letters $X(k)$ are from $\{x_{ij}(t) \mid 1 \leq i \leq n, 1 \leq j \leq r(i), 0 \leq t \leq s\}$ as long as $i \neq n + 1\}$) and $\{w_{ij}, w_x^{\sigma} \mid 1 \leq i \leq n, 1 \leq j \leq 3L(P)\}$. The substitution of $\xi^{lib}_N(t)$ and $W^{(i,j)}_N(t_{ij})$ for $x_{ij}(t)$ and $w_{ij}$, respectively, into the monomial $X$ is denoted by $X_N := X_N(1) \cdots X_N(\ell)$.

Let $X_N(\ell + 1) := A \in M_N(\mathbb{C})$ be arbitrarily chosen. Let $\rho : \mathbb{C}[S_{\ell+1}] \ni (C^N)^{\otimes (\ell + 1)}$, on which $M_N(\mathbb{C})^{\otimes (\ell + 1)}$ acts naturally, be the permutation representation of $S_{\ell+1}$ over the tensor product components; in fact, $\rho(\sigma)(e_1 \otimes \cdots \otimes e_{\ell+1}) = e_{\sigma^{-1}(1)} \otimes \cdots \otimes e_{\sigma^{-1}(\ell+1)}$ for $\sigma \in S_{\ell+1}$. For each $\sigma \in S_{\ell+1}$ we define, following [13, section 3] (rather than Lemma 4.3),

$$\text{tr}_\sigma(X_N(1), \ldots, X_N(\ell), X_N(\ell + 1))$$

$$= \frac{1}{N!} \text{Tr}_N^{(\ell + 1)}(\rho(\sigma)(X_N(1) \otimes \cdots \otimes X_N(\ell) \otimes X_N(\ell + 1)))$$

$$= \prod_{(k_1, \ldots, k_s) \in \sigma} \text{tr}_N(X_N(k_1) \cdots X_N(k_s)),$$

where $(k_1, \ldots, k_s) \leq \sigma$ means that $(k_1, \ldots, k_s)$ is a cycle component of the cycle decomposition of $\sigma \in S_{\ell+1}$, and $\sharp(\sigma)$ denotes the number of cycles in $\sigma$ as in the previous subsection. Note that $\text{tr}_\sigma(\cdots)$ here is not consistent with $\text{tr}_\sigma(\cdots)$ in Lemma 4.3, but $\text{tr}_{\sigma^{-1}}(\cdots) = \text{tr}_\sigma(\cdots)$ holds. In particular, for the cycle $\gamma_{\ell+1} = (1, \ldots, \ell, \ell + 1)$ we have

$$E_W[\text{tr}_{\ell+1}(X_N(1), \ldots, X_N(\ell), A)] = \text{tr}_N(E_W[X_N]A).$$

Then by a slight generalization of [13, Proposition 3.5] (see the next subsection for its precise statement with a detailed proof) there exist universal coefficients $c_\sigma$, $\sigma \in S_{\ell+1}$, depending on
the $t_{ij}$ and $X$, and a universal constant $C > 1$, depending only on $T$ and $L(P)$ due to (14) (and hence only on $P$), such that

$$\left| \text{tr}_N(\mathbb{E}[X_N]A) - \sum_{\sigma \in \mathcal{S}_{\ell+1}} c_\sigma \text{tr}_\sigma(X_N^{(0)}(1), \ldots, X_N^{(0)}(\ell), A) \right| \leq \frac{C}{N^2} \|A\|_{\text{tr}_N, 1}$$

and

$$|c_\sigma| \leq C, \quad \sigma \in \mathcal{S}_{\ell+1}$$

with

$$X_N^{(0)}(k) := \begin{cases} I_N & (X(k) = w_{ij} \text{ or } w_{ij}^*), \\ X_N(k) & \text{(otherwise)}, \end{cases}$$

since $|\text{tr}_\sigma(X_N^{(0)}(1), \ldots, X_N^{(0)}(\ell), A)| \leq (R \lor 1)^L(P) \|A\|_{1, \text{tr}_N}$ (n.b., the procedure from $P$ to $X[P] = \prod_x P$ does not make the number of $x_{ij}(t)$ increase), where $\| - \|_{1, \text{tr}_N}$ denotes the trace norm with respect to the normalized trace $\text{tr}_N$. Since

$$\sum_{\sigma \in \mathcal{S}_{\ell+1}} c_\sigma \text{tr}_\sigma(X_N^{(0)}(1), \ldots, X_N^{(0)}(\ell), A) = \text{tr}_N \left( \sum_{\sigma \in \mathcal{S}_{\ell+1}} c_\sigma \text{tr}_{\sigma^{-1}}[X_N^{(0)}(1), \ldots, X_N^{(0)}(\ell), \ast] A \right)$$

with the notation in Lemma 4.3 and since $A \in M_N(\mathbb{C})$ is arbitrary, we conclude that

$$\left\| \mathbb{E}[X_N] - \sum_{\sigma \in \mathcal{S}_{\ell+1}} c_\sigma \text{tr}_{\sigma^{-1}}[X_N^{(0)}(1), \ldots, X_N^{(0)}(\ell), \ast] \right\|_{M_N(\mathbb{C})} \leq \frac{C}{N^2}. \quad (16)$$

Notice that $\text{tr}_{\sigma^{-1}}[X_N^{(0)}(1), \ldots, X_N^{(0)}(\ell), \ast]$ depends only on the traces $\text{tr}_N$ of monomials in the $\xi_{ij}^{lib}(N)(t)$ (with $0 \leq t \leq s$ as long as $i \neq n + 1$), or other words, the $\tau_{\Xi^{lib}(N)}$ of monomials in the $x_{ij}(t)$ (with $0 \leq t \leq s$ as long as $i \neq n + 1$).

Observe that (16) holds for any monomial $P$ and $s \geq 0$, and we should write $X = X[P] := \prod_x P$, $\ell = \ell_P (= L(X[P]))$, $c_\sigma = c_\sigma(P)$ and $C = C_P$ for clarifying the dependency in what follows. Set

$$X[P]^{(0)}(k) := \begin{cases} 1 & (X[P](k) = w_{ij} \text{ or } w_{ij}^*), \\ X[P](k) & \text{(otherwise)} \end{cases}$$

and for simplicity we write

$$\tau_{\Xi^{\Xi^{\Xi}(N)}}(\sigma; P) := \text{tr}_{\sigma^{-1}}[X[P]^{(0)}(1), \ldots, X[P]^{(0)}(\ell_P), \ast],$$

$$\tau(\sigma; P) := \tau_{\sigma^{-1}}[X[P]^{(0)}(1), \ldots, X[P]^{(0)}(\ell_P), \ast],$$

$$\mathcal{E}(P; \tau_{\Xi^{\Xi^{\Xi}(N)}}) := \sum_{\sigma \in \mathcal{S}_{\ell_P+1}} c_\sigma(P) \tau_{\Xi^{\Xi^{\Xi}(N)}}(\sigma; P),$$

$$\mathcal{E}(P; \tau) := \sum_{\sigma \in \mathcal{S}_{\ell_P+1}} c_\sigma(P) \tau(\sigma; P).$$

We are now finalizing the proof by using what we have prepared so far. Let $P_1, \ldots, P_m$ be any monomials such as the above $P$, that is, all the letters appearing in those are supported in a finite time interval $[0, T]$, and rewrite $\ell_k := \ell_{P_k} = L(X[P_k])$ and set $L := \max\{L(P_k) \mid 1 \leq k \leq m\}$
and $C_0 := \max \{ C_{P_k} \mid 1 \leq k \leq m \}$ for simplicity. We have

$$\left| \text{tr}_N \left( \mathcal{E}(P_1; \tau_{\Xi_{\text{ibh}}(N)}) \cdots \mathcal{E}(P_m; \tau_{\Xi_{\text{ibh}}(N)}) \right) - \tau \left( \mathcal{E}(P_1; \tau) \cdots \mathcal{E}(P_m; \tau) \right) \right|$$

$$\leq \sum_{\sigma_k \in \Theta_{\ell_k+1} (1 \leq k \leq m)} C_{\sigma_1} (P_1) \cdots e_{\sigma_m} (P_m) \times$$

$$\left| \text{tr}_N \left( \tau_{\Xi_{\text{ibh}}(N)} (\sigma_1; P_1) \cdots \tau_{\Xi_{\text{ibh}}(N)} (\sigma_m; P_m) \right) - \tau (\tau(\sigma_1; P_1) \cdots \tau(\sigma_m; P_m)) \right|$$

$$\leq C_0^m \sum_{\sigma_k \in \Theta_{\ell_k+1} (1 \leq k \leq m)} \left| \text{tr}_N \left( \tau_{\Xi_{\text{ibh}}(N)} (\sigma_1; P_1) \cdots \tau_{\Xi_{\text{ibh}}(N)} (\sigma_m; P_m) \right) - \tau (\tau(\sigma_1; P_1) \cdots \tau(\sigma_m; P_m)) \right|$$

by (15). Let $\sigma_k = \sigma_k^{(1)} \cdots \sigma_k^{(l_k)}$ be the cycle decomposition such that the rightmost cycle $\sigma_k^{(l_k)}$ contains $\ell_k + 1$. Then we may and do write

$$\tau_{\Xi_{\text{ibh}}(N)} (\sigma_k; P_k) = \tau_{\Xi_{\text{ibh}}(N)} (Q_k^{(1)} \cdots \tau_{\Xi_{\text{ibh}}(N)} (Q_k^{(l_k)} ) Q_{k,N}^{(1)}),$$

$$\tau(\sigma_k; P_k) = \tau (Q_k^{(1)} \cdots \tau(\sigma_k^{(l_k)}) Q_{k,N}^{(1)}),$$

with some monomials $Q_k^{(i)}$ in the $x_{ij}(t)$, $i \neq n + 1$, $0 \leq t \leq T$, and the $x_{n+1,j}(t)$, whose total length is at most $L(P_k) \leq L$ by construction, possibly with $Q_k^{(1)} = 1$, where $Q_{k,N}^{(1)}$ denotes the substitution of $x_{ij}(N)(t)$ for $x_{ij}(t)$ into $Q_k^{(1)}$. It follows that

$$\left| \text{tr}_N \left( \tau_{\Xi_{\text{ibh}}(N)} (\sigma_1; P_1) \cdots \tau_{\Xi_{\text{ibh}}(N)} (\sigma_m; P_m) \right) - \tau (\tau(\sigma_1; P_1) \cdots \tau(\sigma_m; P_m)) \right|$$

$$\leq \left( \prod_{k=1}^m \left( \tau_{\Xi_{\text{ibh}}(N)} (Q_k^{(1)} \cdots \tau_{\Xi_{\text{ibh}}(N)} (Q_k^{(l_k)} ) Q_{k,N}^{(1)} \cdots Q_k^{(l_k)}) \right) \tau_{\Xi_{\text{ibh}}(N)} (Q_{k,N}^{(1)} \cdots Q_{k,N}^{(l_k)}) \right)$$

$$- \left( \prod_{k=1}^m \tau(Q_k^{(1)} \cdots \tau(\sigma_k^{(l_k)}) \tau(\sigma_k^{(l_k)} \cdots Q_{k,N}^{(1)} \cdots Q_{k,N}^{(l_k)}) \right) \right)$$

$$\leq (1 + \sum_{k=1}^m (\tau(\sigma_k) - 1) \times (R \lor 1)^{L_m} \times 2^{T+1} (2(R \lor 1)^L)^{L_m} d(\tau_{\Xi_{\text{ibh}}(N)}, \tau)$$

$$\leq (9L^2 m + 1) \cdot (R \lor 1)^{L_m} \cdot 2^{T+1} (2(R \lor 1)^L)^{L_m} d(\tau_{\Xi_{\text{ibh}}(N)}, \tau).$$

Remark that $\| \mathbb{E}_W[X[P_k]_N] \|_{M_N(C)} \leq \| X[P_k]_N \|_{M_N(C)} \leq (R \lor 1)^L$ by construction, since the matricial expectation $\mathbb{E}_W[\cdot]$ is a unital positive map, see Remark 4.5. Therefore, (16)–(18) altogether imply that

$$\left| \text{tr}_N \left( \mathbb{E}_W[X[P_1]_N] \cdots \mathbb{E}_W[X[P_m]_N] \right) - \tau \left( \mathcal{E}(P_1; \tau) \cdots \mathcal{E}(P_m; \tau) \right) \right| \leq \frac{C_1}{N^2} + C_2 d(\tau_{\Xi_{\text{ibh}}(N)}, \tau)$$

with constants $C_1, C_2 > 0$ that are independent of the choice of $s$. Then, what we established in the previous subsection, the estimate obtained just above and

$$\mathbb{E}_W[X[P_k]_N] = \mathbb{E}[P_k(\xi_{\text{ibh}}(N)(\cdot), U_N^{(s)}((\cdot) \lor s)U_N^{(s)}(s^*) \mid \mathcal{F}_s) = \mathbb{E}[P_k^{(s)}(\cdot) \mid \mathcal{F}_s], \quad 1 \leq k \leq m$$
altogether force \( \tau \left( \mathcal{E}(P_1; \tau) \cdots \mathcal{E}(P_m; \tau) \right) \) to be \( \tau \left( E_s^*(P_1^{\tau}) \cdots E_s^*(P_m^{\tau}) \right) \), and we finally obtain that

\[
\left| \operatorname{tr} \left( \mathbb{E} \left[ P_{1,N}^{(s)} | F_s \right] \cdots \mathbb{E} \left[ P_{m,N}^{(s)} | F_s \right] \right) - \tau \left( E_s^*(P_1^{\tau}) \cdots E_s^*(P_m^{\tau}) \right) \right| \leq \frac{C_1}{N^2} + C_2 d(\mathbb{E}^{u_{\mathbb{E}N}(N)}, \tau).
\]

Since the right-hand side is independent of the choice of \( s \), the desired uniform (in time \( s \)) convergence follows. \( \square \)

4.3. A slight generalization of [13, Proposition 3.5]. Let \( w = w(1) \cdots w(r) \) be a word in the letters \( d_1, \ldots, d_r \) and \( u^{-1}_1, \ldots, u^{-1}_r \). Define

\[
\varepsilon_k := \begin{cases} +1 & (w(k) = d_s \text{ or } w(k) = u_s^{+1}), \\ -1 & (w(k) = u_s^{-1}) \end{cases}
\]

for \( 1 \leq k \leq r \). In what follows, we may regard \( k \mapsto w(k) \) as a function from \( \{1, \ldots, r\} \) to the letters \( d_i, u_i^{\pm 1} \). Let \( U_N^{(i)}, i = 1, 2, \ldots, \) be independent left unitary Brownian motions as before, and \( D_i \in M_N(\mathbb{C}) \), \( i = 1, 2, \ldots, \), be given matrices. The substitution of \( D_i \) and \( U_N^{(i)}(t_i) \) for \( d_i \) and \( u_i \), respectively, into \( w \) is denoted by

\[
w(D_*, U_N^{(\bullet)}(t*)) = W_N = W_N(1) \cdots W_N(r)
\]

(whose values are taken in \( M_N(\mathbb{C}) \)) with \( W_N(k) = D_i \) or \( W_N(k) = U_N^{(i)}(t_i) \pm 1 \). Moreover, we set

\[
w_\otimes(D_*, U_N^{(\bullet)}(t*)) = W_N^{\otimes} = W_N(1) \otimes \cdots \otimes W_N(r)
\]

(whose values are taken in \( M_N(\mathbb{C})^{\otimes r} \)).

With the permutation representation \( \rho : \mathbb{C} [\mathcal{G}_r] \rightarrow (\mathbb{C}^N)^{\otimes r} \) (see subsection 4.2.2) we write

\[
p_N(t; \sigma) := \mathbb{E} \left[ \frac{1}{N!^r} \operatorname{Tr}^{\otimes r}(\rho(\sigma)W_N^{\otimes}) \right]
\]

with \( t = (t_1, \ldots, t_r) \). (\( n.b. \#(\sigma) \) denotes the number of cycles in \( \sigma \) as before.) The family \( p_N(t; \sigma), \sigma \in \mathcal{G}_r, \) forms an \( r! \) dimension column vector \( p_N(t) \) with indices \( \mathcal{G}_r \). We introduce the operation \( \Pi_{l,m}^{\varepsilon,\delta} \) on \( \mathcal{G}_r, 1 \leq l, m \leq r, \varepsilon, \delta \in \{ \pm 1 \} \), defined by

\[
\Pi_{l,m}^{\varepsilon,\delta}(\sigma) := \begin{cases} \sigma(l,m) & (\varepsilon = \delta = +1), \\ (l,m)\sigma & (\varepsilon = \delta = -1), \\ (\sigma(l),m)\sigma & (\varepsilon = +1, \delta = -1), \\ (\sigma(m),l)\sigma & (\varepsilon = -1, \delta = +1). \end{cases}
\]

A tedious calculation confirms that

\[
\Pi_{l,m}^{\varepsilon,\delta} \circ \Pi_{l',m'}^{\varepsilon',\delta'} = \Pi_{l',m'}^{\varepsilon',\delta'} \circ \Pi_{l,m}^{\varepsilon,\delta} \quad \text{as long as } \{l,m\} \cap \{l',m'\} = \emptyset
\]

for any choice of \( \varepsilon, \varepsilon', \delta, \delta' \). We also define the \( r! \times r! \) matrices \( A_i(w) \) (with indices \( \mathcal{G}_r \)) by setting the \((\sigma,\sigma')\)-entry as

\[
A_i(w)_{\sigma,\sigma'} := -\frac{1}{2} |w^{-1}(\{u_i^{\pm}\})| \delta_{\sigma,\sigma'} - \sum_{l,m \in w^{-1}(\{u_i^{\pm}\})} \varepsilon \varepsilon_m \delta \Pi_{l,m}^{\varepsilon,\varepsilon_m(\sigma),\sigma'}.
\]

where \(|w^{-1}(\{u_i^{\pm}\})|\) denotes the number of elements of \( w^{-1}(\{u_i^{\pm}\}) \) and \( l \sim m \) means that both \( l, m \) are in a common cycle of \( \sigma \). Then the matrices \( A_i(w) \) mutually commute, since the \( w^{-1}(\{u_i^{\pm}\}) \) are disjoint. In what follows, \( \| - \|_{\infty} \) means the \( \ell_\infty \)-norm on the \( r! \)-dimensional
Lemma 3.7]) that for different Brownian motions with constant matrices in the fashion that the convergence as

\[ p_N(t) - \exp \left( \sum_{i=1}^{r} t_i A_i(w) \right) \leq \left\| p_N(t) - \exp \left( \sum_{i=1}^{r} t_i A_i(w) \right) p_N(0) \right\|_{\infty} \]

\[ \leq \frac{1}{2N^2} \left( \sum_{i=1}^{r} t_i \right) \leq \left\| p_N(0) \right\|_{\infty} \leq \frac{1}{\lambda} \right\| p_N(t) \right\|_{\infty} \]

with \( 0 = (0, \ldots, 0) \) and \( T := \max \{ \leq 1 \} \), and furthermore

\[ \left( \exp \left( \sum_{i=1}^{r} t_i A_i(w) \right) \right)_{\sigma, \sigma'} \leq e^{\frac{1}{2} \sum_{i=1}^{r} t_i \left| w^{-1}(\{u_i^{\pm 1}\}) \right|^2} \leq e^{\frac{NT}{2}}. \]

Remark that \( \frac{1}{\lambda} \text{Tr} \left( \rho(\sigma) w_{\otimes} (D_1, I_N) \right) \) is a product of moments in the \( D_i \) with respect to \( \text{tr} \) of degree less than \( r \). Hence the above proposition (together with the method in the previous subsection) strengthens \( \text{Biane's asymptotic freeness result \cite[Theorem 1(2)]{2}} \) for left unitary Brownian motions with constant matrices in the fashion that the convergence as \( N \to \infty \) is uniform on finite time intervals.

**Proof.** (A reproduction of the proof of \cite[Proposition 3.5]{13}.) The algebra \( M_N(\mathbb{C})^{\otimes r} \) has \( r \) different \( M_N(\mathbb{C}) \)-bimodule structures

\[ M_N(\mathbb{C})^{\otimes r} \triangleright M_N(\mathbb{C})^{\otimes r} \triangleright M_N(\mathbb{C}) \]

defined by

\[ \theta^{(+)}_k(X)(Y_1 \otimes \cdots \otimes Y_r) := Y_1 \otimes \cdots \otimes X Y_k \otimes \cdots Y_r, \]

\[ \theta^{(-)}_k(X)(Y_1 \otimes \cdots \otimes Y_r) := Y_1 \otimes \cdots \otimes Y_k X \otimes \cdots Y_r \]

for \( X \in M_N(\mathbb{C}) \) and \( Y_1 \otimes \cdots \otimes Y_r \in M_N(\mathbb{C})^{\otimes r} \). The Itô formula enables us to obtain (see \cite[Lemma 3.7]{13}) that

\[ \frac{\partial}{\partial t_i} p_N(t; \sigma) = -\frac{1}{2} \left| w^{-1}(\{u_i^{\pm 1}\}) \right|^2 p_N(t; \sigma) \]

\[ + \sum_{l,m \in \left( \left\{ u_i^{\pm 1} \right\} \right)} \varepsilon_{l \varepsilon_{m}} \frac{1}{\lambda} \text{Tr} \left( \left( \theta^{(-)}_l \otimes \theta^{(-)}_m \right)(C_{\varepsilon_{U}}(\sigma) \rho(\sigma) W_{\otimes}^2) \right) \left( \text{Tr} \left( \left( \theta^{(+)}_l \otimes \theta^{(-)}_m \right)(C_{\varepsilon_{U}}(\sigma) \rho(\sigma) W_{\otimes}^2) \right) \right) \]

\[ \text{where } C_{\varepsilon_{U}}(\sigma) = \frac{1}{\lambda} \sum_{\alpha, \beta = 1}^{N} E_{\alpha \beta} \otimes E_{\beta \alpha} \text{ with matrix units } E_{\alpha \beta} \text{ for } M_N(\mathbb{C}) \text{.} \]

Then, by \cite[Lemma 3.8 and 3.9]{13} we have

\[ \frac{1}{\lambda} \text{Tr} \left( \left( \theta^{(-)}_l \otimes \theta^{(-)}_m \right)(C_{\varepsilon_{U}}(\sigma) \rho(\sigma) W_{\otimes}^2) \right) \]

\[ \text{where } C_{\varepsilon_{U}}(\sigma) = \frac{1}{\lambda} \sum_{\alpha, \beta = 1}^{N} E_{\alpha \beta} \otimes E_{\beta \alpha} \text{ with matrix units } E_{\alpha \beta} \text{ for } M_N(\mathbb{C}) \text{.} \]

Therefore, with the \( r! \times r! \) matrices \( C_{\varepsilon_{U}}(\sigma) \) (with indices \( \mathcal{S}_r \)):

\[ C_{\varepsilon_{U}}(\sigma)_{\sigma, \sigma'} := - \sum_{l,m \in \left( \left\{ u_i^{\pm 1} \right\} \right)} \varepsilon_{l \varepsilon_{m}} \beta_{\Pi^{(-)}_l, \beta^{(-)}_m}(\sigma, \sigma'), \]
we can rewrite (20) as
\[
\frac{\partial}{\partial t} p_N(t) = (A_i(w) + \frac{1}{N^2} C_i(w))p_N(t) \quad (i = 1, \ldots, r),
\]
which implies that
\[
p_N(t) = \exp \left( \sum_i t_i A_i(w) + \frac{1}{N^2} \sum_i t_i C_i(w) \right) p_N(0),
\]
since the $A_i(w)$ and the $C_i(w)$ mutually commute due to (19).

Let $\| - \|$ denote the operator norm with respect to $\| - \|_\infty$ on the $r!$-dimensional vector space of column vectors. Observe that
\[
\|C_i(w)\| \leq \frac{|w^{-1}(\{u_i^{\pm 1}\})|}{2} \leq \frac{1}{2} |w^{-1}(\{u_i^{\pm 1}\})|^2,
\]
\[
\|A_i(w)\| \leq \frac{1}{2} |w^{-1}(\{u_i^{\pm 1}\})|^2.
\]

Write $A := \sum_i t_i A_i(w)$ and $C := \sum_i t_i C_i(w)$ for simplicity. Then we have
\[
\left\| p_N(t) - (\exp A) p_N(0) \right\|_\infty
\leq \left\| \exp (A + \frac{1}{N^2} C) - \exp A \right\|_\infty \left\| p_N(0) \right\|_\infty
= \left\| \int_0^1 \frac{d}{ds} \left( \exp (s(A + \frac{1}{N^2} C)) \exp((1-s)A) \right) ds \right\| \left\| p_N(0) \right\|_\infty
\leq \left( \int_0^1 \left\| \exp (s(A + \frac{1}{N^2} C)) \left\| \| C \| \left\| \exp((1-s)A) \right\| ds \right\| \left\| p_N(0) \right\|_\infty
\leq \left( \frac{1}{N^2} \| C \| e^\| A \| + \| C \| \int_0^1 e^\| C \| ds \right) \left\| p_N(0) \right\|_\infty
\leq \frac{1}{N^2} \| C \| e^\| A \| + \| C \| \left\| p_N(0) \right\|_\infty
\leq \frac{1}{2N^2} \left( \sum_{i=1}^r t_i |w^{-1}(\{u_i^{\pm 1}\})|^2 \right) \exp \left( \sum_{i=1}^r t_i |w^{-1}(\{u_i^{\pm 1}\})|^2 \right) \left\| p_N(0) \right\|_\infty.
\]

Hence we are done. \qed

5. Large Deviation Upper Bound

This section is concerned with the proof of the desired large deviation upper bound for $\tau_{\Xi_{ub}(N)}$. To this end, we prove in subsection 5.1 the exponential tightness of the sequence of probability measures $\mathbb{P}(\tau_{\Xi_{ub}(N)} \in \cdot)$, and then, in subsection 5.2, introduce and investigate an appropriate rate function by looking at Proposition 3.2. In subsection 5.3, with these preparations, we finalize the proof by using Theorem 4.1 (with Proposition 2.3).

5.1. Exponential tightness. Let us start with the next exponential estimate for left unitary Brownian motions. This lemma is inspired by the proof of [4, Lemma 2.5].

**Proposition 5.1.** Let $U_N$ be an $N \times N$ left unitary Brownian motion as in the introduction. Then
\[
\mathbb{P} \left( \sup_{s \leq t \leq s + \delta} \| U_N(s) - U_N(t) \|_{\text{tr} N, 2} \geq \varepsilon \right) \leq 2\sqrt{2} e^{-N^2 L(e^2 - (8L + 1)\delta)}
\]
holds for every \( s \geq 0, \varepsilon > 0, \delta > 0 \) and \( L > 0 \).

**Proof.** With \( Z_N(t) := \text{tr}_N(2\text{Re}(I_N - U_N(t))) \) we observe that

\[
P\left( \sup_{0 \leq t \leq \delta} \|U_N(s) - U_N(t)\|_{\text{tr}_N,2} \geq \varepsilon \right) = P\left( \sup_{0 \leq t \leq \delta} \|U_N(s) - U_N(s + t)\|_{\text{tr}_N,2}^2 \geq \varepsilon^2 \right)
\]

by the left increment property of left unitary Brownian motions. Thus it suffices to estimate

\[P(\sup_{0 \leq t \leq \delta} Z_N(t) \geq \varepsilon^2)\]

from the above.

One has

\[2\text{Re}(I_N - U_N(t)) = -\int_0^t i(dH_N(s)U_N(s) - U_N(s)^*dH_N(s)) + \int_0^t \text{Re}(U_N(s))ds,\]

since \( dU_N(t) = i dH_N(t)U_N(t) - \frac{1}{2}U_N(t)dt \) with \( N \times N \) self-adjoint Brownian motion \( H_N \). Set

\[
\tilde{M}_N(t) := -\int_0^t i(dH(s)U_N(s) - U_N(s)^*dH(s)) = 2\text{Re}(I_N - U_N(t)) - \int_0^t \text{Re}(U_N(s))ds,
\]

and observe that \( M_N(t) := \text{tr}_N(\tilde{M}_N(t)) = Z_N(t) - \int_0^t \text{Re}(\text{tr}_N(U_N(s)))ds \) defines a martingale. Let \( C_{\alpha\beta} \) be the standard orthogonal basis of \( M_N(\mathbb{C})^{\alpha\alpha} \) as in the introduction. Then \( H_N(t) = \sum_{\alpha, \beta = 1}^N B_{\alpha\beta}(t)C_{\alpha\beta} \) with an \( N^2 \)-dimensional standard Brownian motion \( B_{\alpha\beta} \). This expression enables us to compute the quadratic variation

\[
\langle M_N \rangle(t) = \frac{1}{N^2} \sum_{\alpha, \beta = 1}^N \int_0^t \text{Tr}_N(\text{i}(C_{\alpha\beta}U_N(s) - U_N(s)^*C_{\alpha\beta}))^2 dt = \frac{1}{N^2} \sum_{\alpha, \beta = 1}^N \int_0^t \text{Tr}_N(\text{i}(U_N(s) - U_N(s)^*)C_{\alpha\beta})^2 dt = \frac{1}{N^2} \int_0^t \|i(U_N(s) - U_N(s)^*)\|_{\text{tr}_N,2}^2 dt \leq \frac{4t}{N^2}
\]

as in section 3.

Note that \( Z_N(t) = M_N(t) + \int_0^t \text{Re}(\text{tr}_N(U_N(s)))ds \leq |M_N(t)| + t \). Hence, if \( \sup_{0 \leq t \leq \delta} Z_N(t) \geq \varepsilon^2 \), then we have both \( \sup_{0 \leq t \leq \delta} |M_N(t)| \geq \varepsilon^2 - \delta \) and

\[
\sup_{0 \leq t \leq \delta} \exp(-N^2LM_N(t)) + \sup_{0 \leq t \leq \delta} \exp(N^2LM_N(t)) \geq \sup_{0 \leq t \leq \delta} \left( \exp(-N^2LM_N(t)) + \exp(N^2LM_N(t)) \right) \geq \sup_{0 \leq t \leq \delta} \exp(N^2L|M_N(t)|) \geq e^{N^2L(\varepsilon^2 - \delta)}
\]

for any fixed \( L > 0 \). Thus we get

\[P\left( \sup_{0 \leq t \leq \delta} Z_N(t) \geq \varepsilon^2 \right) \leq P\left( \sup_{0 \leq t \leq \delta} |M_N(t)| \geq \varepsilon^2 - \delta \right)\]
\[ \leq e^{-N^2 L(\varepsilon^2 - \delta)} \left\{ E \left[ \sup_{0 \leq t \leq \delta} \exp(-N^2 L M_N(t)) \right] + E \left[ \sup_{0 \leq t \leq \delta} \exp(N^2 L M_N(t)) \right] \right\} \]

by Chebyshev’s inequality. We have

\[ E \left[ \sup_{0 \leq t \leq \delta} \exp(\pm N^2 L M_N(t)) \right] = E \left[ \sup_{0 \leq t \leq \delta} \left( \exp \left( \pm N^2 L M_N(t) - \frac{1}{2} \langle \pm N^2 L M_N(t) \rangle \right) \exp \left( \frac{1}{2} \langle \pm N^2 L M_N(t) \rangle \right) \right) \right] \leq E \left[ \sup_{0 \leq t \leq \delta} \exp \left( \pm N^2 L M_N(t) - \frac{1}{2} \langle \pm N^2 L M_N(t) \rangle \right) \right] \]

\[ \leq E \left[ \sup_{0 \leq t \leq \delta} \exp \left( \pm N^2 L M_N(t) - \frac{1}{2} \langle \pm N^2 L M_N(t) \rangle \right) \right] ^{1/2} \left[ \exp \left( \frac{1}{2} \langle \pm N^2 L M_N(t) \rangle \right) \right] ^{1/2} \]

by the Cauchy–Schwarz inequality. Since \( t \mapsto \exp \left( \pm N^2 L M_N(t) - \frac{1}{2} \langle \pm N^2 L M_N(t) \rangle \right) \) and \( t \mapsto \exp \left( \pm 4N^2 L M_N(t) - \frac{1}{2} \langle \pm 4N^2 L M_N(t) \rangle \right) \) are martingales thanks to [11, Corollary 3.5.13], Doob’s maximal inequality with \( p = 2 \) (see e.g., [11, Theorem 1.3.8(iv)] with the help of Jensen’s inequality) shows that

\[ E \left[ \sup_{0 \leq t \leq \delta} \exp \left( \pm N^2 L M_N(t) - \frac{1}{2} \langle \pm N^2 L M_N(t) \rangle \right) \right] \leq 2 E \left[ \exp \left( \pm N^2 L M_N(\delta) - \frac{1}{2} \langle \pm N^2 L M_N(\delta) \rangle \right) \right] ^{1/2} \left[ \exp \left( \frac{1}{2} \langle \pm N^2 L M_N(\delta) \rangle \right) \right] ^{1/2} \]

\[ \leq 2 E \left[ \exp \left( \pm 2N^2 L M_N(\delta) - 4\langle \pm N^2 L M_N(\delta) \rangle \right) \right] ^{1/2} \left[ \exp \left( 3\langle \pm N^2 L M_N(\delta) \rangle \right) \right] ^{1/2} \]

\[ = 2 E \left[ \exp \left( \pm 4N^2 L M_N(\delta) - \frac{1}{2} \langle \pm 4N^2 L M_N(\delta) \rangle \right) \right] ^{1/2} \left[ \exp \left( \frac{6}{2} \langle \pm N^2 L M_N(\delta) \rangle \right) \right] ^{1/2} \]

\[ = 2 E \left[ \exp \left( 6N^2 L^2 \langle M_N(\delta) \rangle \right) \right] ^{1/2} . \]

Therefore, we have

\[ E \left[ \sup_{0 \leq t \leq \delta} \exp(\pm N^2 L M_N(t)) \right] \leq \sqrt{2} E \left[ \exp \left( 6N^4 L^2 \langle M_N(\delta) \rangle \right) \right] ^{1/4} E \left[ \exp \left( N^4 L^2 \langle M_N(\delta) \rangle \right) \right] \sqrt{2} e^{8N^2 L^2 \delta} . \]

Hence we get

\[ P \left( \sup_{0 \leq t \leq \delta} Z_N(t) \geq \varepsilon^2 \right) \leq e^{-N^2 L(\varepsilon^2 - \delta)} \times 2 \times \sqrt{2} e^{8N^2 L^2 \delta} = 2\sqrt{2} e^{-N^2 L(\varepsilon^2 - (8L+1)\delta)} \]

for every \( L > 0. \)

\[ \square \]

**Corollary 5.2.** The sequence of probability measures \( P(\tau_{\Xi_{\text{mix}}(N)} \in \cdot) \) on \( TS^c(C^*_R(x \circ \cdot)) \) is exponentially tight.
Proof. Observe that
\[
\sup_{0 \leq s, t \leq k} \max_{1 \leq i \leq n+1} \tau \Xi_{ib}(N) \left( (x_{ij}(s) - x_{ij}(t))^2 \right)^{1/2} 
\leq \sup_{0 \leq t \leq [k/\delta]} \max_{1 \leq j \leq r(i)} \sum_{1 \leq i \leq n+1} \tau \Xi_{ib}(N) \left( (x_{ij}(s) - x_{ij}(t))^2 \right)^{1/2} 
\leq \sup_{0 \leq t \leq [k/\delta]} \max_{1 \leq j \leq r(i)} \sum_{1 \leq i \leq n+1} \left( \tau \Xi_{ib}(N) \left( (x_{ij}(s) - x_{ij}(t))^2 \right)^{1/2} + \tau \Xi_{ib}(N) \left( (x_{ij}(s) - x_{ij}(t))^2 \right)^{1/2} \right) 
\leq 2 \sup_{0 \leq t \leq [k/\delta]} \max_{1 \leq j \leq r(i)} \sum_{1 \leq i \leq n+1} \left( \tau \Xi_{ib}(N) (x_{ij}(s) - x_{ij}(t))^2 \right)^{1/2} 
\leq 4R \max_{1 \leq i \leq n+1} \sup_{0 \leq t \leq [k/\delta]} \sup_{(t+\delta) \leq \ell \leq (t+2\delta)} \left\| U_N^{(i)}(N\ell) - U_N^{(i)}(t) \right\|_{trN,2}.
\]
where \( \ell \) is a parameter of non-negative integers and \( [k/\delta] \) denotes the greatest non-negative integer that is not greater than \( k/\delta \). Hence, for each \( k \in \mathbb{N} \) and for any \( \delta > 0 \) and \( L > 0 \), we have
\[
P \left( \sup_{0 \leq s, t \leq k} \max_{1 \leq i \leq n+1} \tau \Xi_{ib}(N) \left( (x_{ij}(s) - x_{ij}(t))^2 \right)^{1/2} > 1/k \right) 
\leq P \left( \max_{1 \leq i \leq n+1} \sup_{0 \leq t \leq [k/\delta]} \left\| U_N^{(i)}(N\ell) - U_N^{(i)}(t) \right\|_{trN,2} \geq \frac{1}{4Rk} \right) 
\leq \sum_{\ell=0}^{[k/\delta]} \sum_{i=1}^{n} \left( \sup_{0 \leq t \leq [k/\delta]} \left\| U_N^{(i)}(N\ell) - U_N^{(i)}(t) \right\|_{trN,2} \geq \frac{1}{4Rk} \right) 
\leq 2\sqrt{n} \left( \frac{[k/\delta] + 1}{e} \right) e^{-N^2L(16R^2k^2)^{-1} - (8L+1)2\delta}
\]
by Proposition 5.1. Therefore, for a given \( C > 0 \), letting
\[
L := 32R^2k^3C \quad \text{and} \quad \delta_k := \frac{1}{64R^2k^2(256R^2k^3C + 1)},
\]
we obtain the following estimate:
\[
P \left( \tau \Xi_{ib}(N) \notin \Gamma \right) 
\leq \sum_{k=1}^{\infty} P \left( \sup_{0 \leq s, t \leq k} \max_{1 \leq i \leq n+1} \tau \Xi_{ib}(N) \left( (x_{ij}(s) - x_{ij}(t))^2 \right)^{1/2} > \frac{1}{k} \right) 
\leq C'(k^6 e^{-N^2Ck/2}) e^{-N^2Ck/2},
\]
where \( C' > 0 \) depends only on \( n, R, C \) and is independent of \( k, N \). If \( C > 12 \), then \( k^6 e^{-N^2Ck/2} \leq e^{-N^2C/2} \). With the sequence \( \delta_k \), it follows that
\[
P \left( \tau \Xi_{ib}(N) \notin \Gamma \right) 
\leq \sum_{k=1}^{\infty} P \left( \sup_{0 \leq s, t \leq k} \max_{1 \leq i \leq n+1} \tau \Xi_{ib}(N) \left( (x_{ij}(s) - x_{ij}(t))^2 \right)^{1/2} > \frac{1}{k} \right) 
\leq C' e^{-N^2C} \frac{1}{1 - e^{-N^2C/2}},
\]
implying that \( \lim_{n \to \infty} \frac{1}{n} \log P \left( \tau \Xi_{ib}(N) \notin \Gamma \right) \leq -C \) whenever \( C > 12 \). This together with Lemma 2.2(2) shows the exponential tightness of the measures \( P(\tau \Xi_{ib}(N) \in \cdot) \), since \( C > 0 \) can arbitrarily be large. \( \square \)
5.2. Rate function. We define a map $I^\text{lib}_{\sigma_0} : TS^+(C^*_R(x_{\text{lib}}(\cdot))) \to [0, +\infty]$ to be
\[
\sup_{T \geq 0 \atop P = P^* \in C(x_{\text{lib}}(\cdot))} \left\{ \tau^T(P) - \sigma^\text{lib}_0(P) - \frac{1}{2} \sum_{k=1}^n \int_0^T \left\| E^\tau_s((\mathbf{D}^k_s(P))(x_{\text{lib}}^\tau(\cdot), v^\tau(\cdot))) \right\|^2_{_{\tau,2}} ds \right\}.  \tag{21}
\]
That the integrand is piece-wisely continuous in $s$ follows from Lemma 5.5 below together with (22): Note that $i \mathbf{D}^k_s(P)$ is self-adjoint if $P = P^*$, and then
\[
\left\| E^\tau_s((\mathbf{D}^k_s(P))(x_{\text{lib}}^\tau(\cdot), v^\tau(\cdot))) \right\|^2_{_{\tau,2}} = \left\| E^\tau_s((i \mathbf{D}^k_s(P))(x_{\text{lib}}^\tau(\cdot), v^\tau(\cdot))) \right\|^2_{_{\tau,2}}
\]
\[
= -\tau \left( E^\tau_s((\mathbf{D}^k_s(P))(v^\tau(\cdot - s) \vee 0) x_{\text{lib}}^\tau(\cdot \wedge s) v^\tau(\cdot - s) \vee 0)^2 \right)^2
\]  \tag{22}
holds for every $P = P^* \in C(x_{\text{lib}}(\cdot))$.

Lemma 5.3. If $I^\text{lib}_{\sigma_0}(\tau) < +\infty$, then $\tau^0 = \sigma^\text{lib}_0$, that is, $\pi^0_0(\tau) = \sigma_0$, and
\[
I^\text{lib}_{\sigma_0}(\tau) = \frac{1}{2} \sup_{T \geq 0 \atop P = P^* \in C(x_{\text{lib}}(\cdot))} \left\{ \frac{(\tau^T(P) - \sigma^\text{lib}_0(P))^2}{\sum_{k=1}^n \int_0^T E^\tau_s((\mathbf{D}^k_s(P))(x_{\text{lib}}^\tau(\cdot), v^\tau(\cdot)))^2_{_{\tau,2}} ds} \right\}
\]
holds (and the right-hand side is well-defined with convention $0/0 = 0$, that is, if the denominator is zero, then the numerator must be zero).

Proof. For each fixed $P = P^* \in C(x_{\text{lib}}(\cdot))$, let $\alpha_T(P) := \tau^T(P) - \sigma^\text{lib}_0(P)$ and $\beta_T(P) := \sum_{k=1}^n \int_0^T \left\| E_s^\tau((\mathbf{D}^k_s(P))(x_{\text{lib}}^\tau(\cdot), v^\tau(\cdot))) \right\|^2_{_{\tau,2}} ds$, and consider the function
\[
f_{P,T}(r) := \alpha_T(P) - \frac{\beta_T(P)}{2} = \alpha_T(P) r - \frac{\beta_T(P)}{2} \frac{r^2}{\alpha_T(P)} - \frac{\beta_T(P)}{2} r^2
\]
on the real line. If $\beta_T(P) \not\geq 0$, then $\max_r f_{P,T}(r) = f_{P,T}(\alpha_T(P)/\beta_T(P)) = \alpha_T(P)^2/2\beta_T(P)$; otherwise
\[
\sup_r f_{P,T}(r) = \sup_r \alpha_T(P)r = \begin{cases} 0 & (\alpha_T(P) = 0), \\ +\infty & (\alpha_T(P) \neq 0). \end{cases}
\]
Trivially $\beta_0(P) = 0$ always holds, and hence the above discussion shows that $\alpha_0(P)$ must be 0 for every $P$, from $I^\text{lib}_{\sigma_0}(\tau) < +\infty$. Therefore, we have proved the former assertion $\tau^0 = \sigma^\text{lib}_0$.

For any $\varepsilon > 0$, there exist $P_\varepsilon = P^*_\varepsilon \in C(x_{\text{lib}}(\cdot))$ and $T_\varepsilon \geq 0$ so that $I^\text{lib}_{\sigma_0}(\tau) - \varepsilon < f_{P_\varepsilon,T_\varepsilon}(1) \leq \max_r f_{P_\varepsilon,T_\varepsilon}(r) \leq I^\text{lib}_{\sigma_0}(\tau) + \varepsilon$. Then, the first paragraph shows that
\[
I^\text{lib}_{\sigma_0}(\tau) - \varepsilon \leq \frac{\alpha_T(P_\varepsilon)^2}{2\beta_T(P_\varepsilon)} \leq \sup_{P,T} \frac{\alpha_T(P)^2}{2\beta_T(P)} = \sup_{P,T} \max_r f_{P,T}(r) \leq I^\text{lib}_{\sigma_0}(\tau)
\]
with convention $0/0 = 0$. Hence the latter assertion holds.

Here is a simple lemma.

Lemma 5.4. Let $(\mathcal{M}, \tau)$ be a tracial $W^*$-probability space with $\tau$ faithful, and $u \in \mathcal{M}$ be a unitary, and $\mathcal{N}$ be a (unital) $W^*$-subalgebra of $\mathcal{M}$. Let $E : \mathcal{M} \to \mathcal{N}$ be the unique $\tau$-preserving conditional expectation. If $u$ is $*$-freely independent of $\mathcal{N}$ we have $E(u x u^*) = \tau(x)1 + |\tau(u)|^2 x^0$ for every $x \in \mathcal{N}$ with $x^0 := x - \tau(x)1$.

Proof. For every $y \in \mathcal{N}$, we have $\tau(u x u^* y) = \tau(x)\tau(y) + |\tau(u)|^2 \tau(x^2) y$ by the $*$-free independ-ence between $u$ and $\mathcal{N}$. Since $E(u x u^*) \in \mathcal{N}$ is uniquely determined by the relation $\tau(u x u^* y) = \tau(E(u x u^*) y)$ for every $y \in \mathcal{N}$, the desired assertion immediately follows.

The same idea as above shows the next lemma.
Lemma 5.5. Let $(\mathcal{M}, \tau)$ be a tracial $W^*$-probability space with $\tau$ faithful. Let $\mathcal{L}$ and $\mathcal{N}$ be freely independent (unital) $W^*$-subalgebras of $\mathcal{M}$, and $E : \mathcal{M} \to \mathcal{N}$ be the unique $\tau$-preserving conditional expectation. Then $(a_1, \ldots, a_{n-1}, a_n), (b_1, \ldots, b_n) \in \mathcal{L}^n \times \mathcal{N}^m \mapsto E(a_1 b_1 \cdots a_{n-1} b_n a_n) \in \mathcal{N}$ is written as a universal polynomial in moments of the $a_i$, moments of the $b_i$ and words in the $b_i$.

Proof. Let us calculate the map

$$(a_1, \ldots, a_{n-1}, a_n), (b_1, \ldots, b_n) \in \mathcal{L}^n \times \mathcal{N}^m \mapsto \tau(a_1 b_1 \cdots a_{n-1} b_n a_n).$$

By [15, Proposition 11.4, Theorem 11.16] $\tau(a_1 b_1 \cdots a_{n-1} b_n a_n)$ is a universal polynomial in moments of the $a_i$ and moments of the $b_i$. Since the map

$$(a_1, \ldots, a_{n-1}, a_n), (b_1, \ldots, b_n) \mapsto \tau(a_1 b_1 \cdots a_{n-1} b_n a_n)$$

is multilinear, each term of the polynomial includes some joint moments of the $b_i$, where $b_n$ appears only once in a unique joint moment. Then we can obtain the desired assertion in the same way as in the proof of Lemma 5.4. □

We remark that the universal polynomial whose existence we have established admits an explicit formula based on the notation in [15, Lecture 11].

Here is a main result of this subsection.

Proposition 5.6. $I^{\text{lib}}_{\sigma_0} : TS^c(C^*_R(\mathfrak{x}_0(\cdot))) \to [0, +\infty]$ is a good rate function.

Proof. By (22) together with Lemma 5.5 we observe that

$$\tau \mapsto \|E^\tau_s((\mathcal{D}_s^{(k)} P)(\mathfrak{x}_0^\tau(\cdot), \nu_s^\tau(\cdot)))\|^2_{\tau^2}$$

is a continuous function for every $s$. Hence

$$\tau \mapsto I_{\rho_1^T}(\tau) := \tau^T(P) - \sigma_0^\text{lib}(P) - \frac{1}{2} \sum_{k=1}^n \int_0^T \|E^\tau_s((\mathcal{D}_s^{(k)} P)(\mathfrak{x}_0^\tau(\cdot), \nu_s^\tau(\cdot)))\|^2_{\tau^2} \, ds$$

is continuous, and consequently, $I^{\text{lib}}_{\sigma_0}$ is lower semicontinuous. Therefore, it suffices to prove that the level set $\{I^{\text{lib}}_{\sigma_0} \leq \lambda\}$ sits in a compact subset for every non-negative real number $\lambda \geq 0$.

Assume that $I^{\text{lib}}_{\sigma_0}(\tau) \leq \lambda$. By Lemma 5.3 we have

$$\tau^T(P) \leq \sigma_0^\text{lib}(P) + \sqrt{2\lambda \sum_{k=1}^n \int_0^T \|E^\tau_s((\mathcal{D}_s^{(k)} P)(\mathfrak{x}_0^\tau(\cdot), \nu_s^\tau(\cdot)))\|^2_{\tau^2} \, ds}$$

(23)

for every $P = P^* \in \mathcal{C}(\mathfrak{x}_0(\cdot))$ and $T \geq 0$.

For $0 \leq t_1 < t_2$ we have

$$\mathcal{D}^{(k)}_s((x_{ij}(t_1) - x_{ij}(t_2))^2) = 2\delta_{k,i} \{1_{[0,t_1]}(s)v_i(t_1 - s)^* [x_{ij}(t_1), x_{ij}(t_2)]v_i(t_1 - s)$$

$$+ 1_{[0,t_2]}(s)v_i(t_2 - s)^* [x_{ij}(t_2), x_{ij}(t_1)]v_i(t_2 - s)\},$$

and hence

$$\mathcal{D}^{(k)}_s((x_{ij}(t_1) - x_{ij}(t_2))^2)(x_{ij}^\tau(\cdot), \nu_s^\tau(\cdot))$$

$$= \left\{ \begin{array}{ll}
2\delta_{k,i} \{[x_{ij}^\tau(s), v_i^\tau(t_1 - s)^* v_i^\tau(t_2) - s)x_{ij}^\tau(s)v_i^\tau(t_2 - s)^* v_i^\tau(t_1 - s)]
+ [x_{ij}^\tau(s), v_i^\tau(t_2 - s)^* v_i^\tau(t_1 - s)]x_{ij}^\tau(s)v_i^\tau(t_1 - s)^* v_i^\tau(t_2 - s)]
\} (s \leq t_1),

2\delta_{k,i}[x_{ij}^\tau(s), v_i^\tau(t_2 - s)^* x_{ij}^\tau(t_1)v_i^\tau(t_2 - s)]
\} (t_1 < s \leq t_2),

0 (t_2 < s),
\end{array} \right.$$
When $s \leq t_1$, Lemma 5.4 enables us to compute
\[
E_s^T \left( \left( x_{ij}(t_1) - x_{ij}(t_2) \right)^2 \right) (x_{ij}^T (.), v_1^T (.) )
\]
\[
= 2\delta_{k,i} \left\{ x_{ij}^T (s), E_s^T \left( v_1^T (t_1 - s)^* v_1^T (t_2 - s) x_{ij}^T (s) v_1^T (t_2 - s)^* v_1^T (t_1 - s) \right) \right\}
+ \left[ x_{ij}^T (s), E_s^T \left( v_1^T (t_2 - s)^* v_1^T (t_1 - s) x_{ij}^T (s) v_1^T (t_1 - s)^* v_1^T (t_2 - s) \right) \right]
\]
\[
= 2\delta_{k,i} \left\{ x_{ij}^T (s), (\tau(x_{ij}^T (s)) 1 + |\tau(v_1^T (t_1 - s)^* v_1^T (t_2 - s))|^2 x_{ij}^T (s)^2) \right\}
+ \left[ x_{ij}^T (s), (\tau(x_{ij}^T (s)) 1 + |\tau(v_1^T (t_2 - s)^* v_1^T (t_1 - s))|^2 x_{ij}^T (s)^2) \right]
\]
\[
= 0.
\]
In this way, we obtain the formula:
\[
E_s^T \left( \left( x_{ij}^T (t_1) - x_{ij}^T (t_2) \right)^2 \right) (x_{ij}^T (.), v_1^T (.) )
= 2\delta_{k,i} \mathbf{1}_{(t_1, t_2)} (s) |\tau(v_1^T (t_2 - s))|^2 [x_{ij}^T (s), x_{ij}^T (t_1)]^0.
\]
(24)
Then, (23) with $P := (x_{ij}(t_1) - x_{ij}(t_2))^2$ and $T$ large enough, and (24) altogether show that
\[
\tau((x_{ij}(t_1) - x_{ij}(t_2))^2) \leq \sigma^{lib}_0((x_{ij}(t_1) - x_{ij}(t_2))^2) + 8R^2 \sqrt{2\lambda} |t_1 - t_2|.
\]
By the construction of $\sigma^{lib}_0$ (see section 2), we see that $\sigma^{lib}_0((x_{n+1,j}(t_1) - x_{n+1,j}(t_2))^2) = 0$ and moreover that, if $1 \leq i \leq n$, then
\[
\sigma^{lib}_0((x_{ij}(t_1) - x_{ij}(t_2))^2) = \|v_i(t_1)x_{ij}^{\sigma_0}v_i(t_1)^* - v_i(t_2)x_{ij}^{\sigma_0}v_i(t_2)^*\|^2_{\sigma_0^2}
\]
\[
\leq (2R\|v_i(t_1) - v_i(t_2)\|_{\sigma_0^2})^2
\]
\[
= 4R^2 \|v_i(t_1 - t_2) - 1\|^2_{\sigma_0^2} \to 0
\]
as $|t_1 - t_2| \to 0$. Hence, by Lemma 2.2(2), \{ $I^{lib}_{\sigma_0^2} \leq \lambda$ \} sits inside a compact subset. 

We give a few important properties on the rate function $I^{lib}_{\sigma_0^2}$.

**Proposition 5.7.** For any $\tau \in TS^c(C^*_R (x_\bullet (\cdot )))$ we have:

1. $I^{lib}_{\sigma_0^2} \tau < +\infty$ implies that $t \mapsto x_{n+1,j}(t)$ is a constant process for every $1 \leq j \leq r(n+1)$.
2. $I^{lib}_{\sigma_0^2} \tau < +\infty$ implies that for each fixed $1 \leq i \leq n$ and $t \geq 0$, we have $\pi_t^\tau (P) = \sigma_0^2(P)$ for every non-commutative polynomial $P$ in indeterminates $x_{ij}$, $1 \leq j \leq r(i)$.
3. $I^{lib}_{\sigma_0^2} \tau = 0$ if and only if $\tau = \sigma_0^2$. Hence $\sigma^{lib}_0$ is a unique minimizer of $I_{\sigma_0^2}$.

**Proof.** (1) By (23) and (24) we have $\|x_{n+1,j}^\tau(t) - x_{n+1,j}^\tau(0)\|^2_{\sigma_0^2} \leq \|x_{n+1,j}^{\sigma_0^2}(t) - x_{n+1,j}^{\sigma_0^2}(0)\|^2_{\sigma_0^2} = \|x_{n+1,j}^\tau(t) - x_{n+1,j}^\tau(0)\|^2_{\sigma_0^2} = 0$. Hence $x_{n+1,j}^\tau(t) = x_{n+1,j}^\tau(0)$ holds for every $t \geq 0$.

(2) Let $P$ be an arbitrary, non-commutative polynomial in indeterminates $x_{ij}$, $1 \leq j \leq r(i)$, with a fixed $1 \leq i \leq n$. It is easy to see that $D^{\sigma_0^2} P(x_{\bullet^i}^\tau) = 0$. Hence we have
\[
\left( \tau^T(P) - \pi_t^\tau(\sigma_0^2(P)) \right) = \tau^T(R_{\pi_t^\tau}(P) - \sigma_0^2(P)) \leq I_{\sigma_0^2}(\tau) < +\infty
\]
for every $r \in \mathbb{R}$ and $T \geq 0$, and thus $\pi_t^\tau(P) = \pi_t^\tau(\tau^T(P)) = \pi_t^\tau(\sigma_0^2(P)) = \sigma_0^2(P)$ with $T$ large enough.

(3) By the left increment property of left free unitary Brownian motions (see [2, Definition 2]), it is easy to see that $(\sigma_0^2)^T = \sigma_0^2$ holds for every $T \geq 0$. Thus, we trivially obtain that
\[
I_{\sigma_0^2}(\sigma_0^2) = \lim_{T \to 0} \sup_{P = P^* \in C(x_{\bullet^i}(\cdot ))} \left\{ - \int_0^T \sum_{k=1}^n \|D_{\tau_s^T} \left( \left( x_{\bullet^i}^T(\cdot) , v_1^T(\cdot) \right) \right) \|^2_{\sigma_0^2} ds \right\} = 0.
\]
Lemma 5.3 with its proof actually shows that \( I_{\sigma_0}^{\text{lib}}(\tau) = 0 \) implies that
\[
0 \leq \frac{\left( \tau^T(P) - \sigma_0^{\text{lib}}(P) \right)^2}{2 \sum_{k=1}^n \int_0^T \| E_s^k((D_s^k P)(x_{\nu}(\cdot), \nu_{\nu}(\cdot))) \|_{\tau,s}^2 \, ds} \leq I_{\sigma_0}^{\text{lib}}(\tau) = 0
\]
(with convention \( 0/0 = 0 \)) for all \( P = P^* \in C(x_{\nu}(\cdot)) \) and \( T \geq 0 \). This (with the proviso in Lemma 5.3) actually shows that \( \tau^T(P) = \sigma_0^{\text{lib}}(P) \) holds for every \( P = P^* \in C(x_{\nu}(\cdot)) \) and \( T \geq 0 \). This immediately implies that \( \tau = \sigma_0^{\text{lib}} \).

These properties actually show that \( I_{\sigma_0}^{\text{lib}} \) is indeed a ‘right’ rate function for our purpose. Further analysis of this rate function \( I_{\sigma_0}^{\text{lib}} \) will be given in a sequel to this article.

5.3. Main results. We are ready to prove the next main result of this article.

**Theorem 5.8.** For every closed subset \( \Lambda \) of \( TS^c(C^*_R(x_{\nu}(\cdot))) \) we have
\[
\lim_{N \to \infty} \frac{1}{N^2} \log \mathbb{P}(\tau_{\Xi}^{\text{lib}}(N) \in \Lambda) \leq - \inf \{ I_{\sigma_0}^{\text{lib}}(\tau) \mid \tau \in \Lambda \}.
\]

**Proof.** Since the \( \mathbb{P}(\tau_{\Xi}^{\text{lib}}(N) \in \cdot) \) form an exponentially tight sequence of probability measures and \( I_{\sigma_0}^{\text{lib}} \) is a good rate function, it suffices to prove the following weak large deviation upper bound:
\[
\lim_{\varepsilon \downarrow 0} \lim_{N \to \infty} \frac{1}{N^2} \log \mathbb{P}(d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon) \leq - I_{\sigma_0}^{\text{lib}}(\tau)
\]
for every \( \tau \in TS^c(C^*_R(x_{\nu}(\cdot))) \). (This is a standard fact in large deviation theory; see the proofs of [6, Theorem 4.1.11, Lemma 1.2.18].)

Consider the random variable
\[
I_{P,T,N} := \mathbb{E}[\tau_{\Xi}^{\text{lib}}(N) \mid \mathcal{F}_T] - \mathbb{E}[\tau_{\Xi}^{\text{lib}}(N)] - \frac{1}{2} \sum_{k=1}^n \int_0^T \| E_s^k((D_s^k P)(x_{\nu}(\cdot), \nu_{\nu}(\cdot)), U_N^k(\cdot + s)U_N^k(s)^*) \|_{\tau,s}^2 \, ds.
\]

By Proposition 3.2 we have
\[
\mathbb{E}[\exp(N^2 I_{P,T,N})] = \mathbb{E}[\exp(N^2 I_{P,0,N})] = 1.
\]

Let \( I_{P,T}(\tau) \) be as in the proof of Proposition 5.6. We have
\[
\mathbb{P}(d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon) \leq \mathbb{E} \left[ \mathbb{1}_{\{ d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon \}} \exp(N^2 I_{P,T,N} - N^2 I_{P,T,N}) \right] \\
\leq \mathbb{E} \left[ \mathbb{1}_{\{ d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon \}} \exp(N^2 I_{P,T,N}) \right] \\
\times \text{esssup} \left\{ \exp(-N^2 I_{P,T,N}) \mid d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon \right\} \\
\leq \text{esssup} \left\{ \exp(-N^2 I_{P,T,N}) \mid d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon \right\} \text{ (use (25))} \\
= \exp \left( -N^2 \text{essinf} \{ I_{P,T,N} \mid d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon \} \right).
\]

Observe that
\[
I_{P,T,N} \geq I_{P,T}(\tau) - I_{P,T,N} - I_{P,T}(\tau) \geq I_{P,T}(\tau) - \text{esssup} \{ I_{P,T,N} - I_{P,T}(\tau) \mid d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon \}
\]
holds almost surely on \( \{ d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon \} \). Therefore, we conclude that
\[
\frac{1}{N^2} \log \mathbb{P}(d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon) \leq - I_{P,T}(\tau) + \text{esssup} \{ I_{P,T,N} - I_{P,T}(\tau) \mid d(\tau_{\Xi}^{\text{lib}}(N), \tau) < \varepsilon \}.
\]
Then Proposition 2.3 and Corollary 4.2 (together with (3) and (22)) show that
\[
\lim_{\varepsilon \searrow 0} \lim_{N \to \infty} \text{esssup}\left\{|I_{P,T,N} - I_{P,T}(\tau)| \left| d(\tau_{\Xi(N)}, \tau) < \varepsilon \right\} = 0,
\]
and hence
\[
\lim_{\varepsilon \searrow 0} \lim_{N \to \infty} \frac{1}{N^2} \log \mathbb{P}\left(d(\tau_{\Xi(N)}, \tau) < \varepsilon \right) \leq -I_{P,T}(\tau)
\]
for every \(P = P^* \in \mathbb{C}(x_{\infty}(\cdot))\) and \(T \geq 0\). Hence we are done. \(\square\)

Here is a standard application of the above large deviation upper bound and Proposition 5.7(3).

**Corollary 5.9.** We have \(\lim_{N \to \infty} d(\tau_{\Xi(N)}, \sigma^\text{lib}_0) = 0\) almost surely.

**Proof.** Let \(\varepsilon > 0\) be arbitrarily chosen. By Proposition 5.6 and Proposition 5.7(3) we observe that \(\inf \{I^\text{lib}_{\sigma_0}(\tau) \mid d(\tau, \sigma^\text{lib}_0) \geq \varepsilon\} \geq 0\). Then, Theorem 5.8 implies that
\[
\lim_{N \to \infty} \frac{1}{N^2} \log \mathbb{P}(d(\tau_{\Xi(N)}, \sigma^\text{lib}_0) \geq \varepsilon) \leq -\inf \{I^\text{lib}_{\sigma_0}(\tau) \mid d(\tau, \sigma^\text{lib}_0) \geq \varepsilon\} \leq 0.
\]
Thus we obtain that \(\sum_{N=1}^{\infty} \mathbb{P}(d(\tau_{\Xi(N)}, \sigma^\text{lib}_0) \geq \varepsilon) < +\infty\). Hence the desired assertion follows by the Borel–Cantelli lemma. \(\square\)

### 6. Discussions

One of the motivations in mind is to provide a common basis for the study of Voiculescu’s approach ([22]) and our orbital approach ([8],[19]) to the concept of mutual information in free probability. In fact, the key ingredient of Voiculescu’s approach is the liberation process, while the orbital approach involves ‘orbital microstates’ by unitary matrices. Thus, a serious lack was a random matrix counterpart of liberation process, whose candidate we introduced in this article. Here we are not going to any detailed discussions about such a study, but only give some comments on it.

We may apply the contraction principle in large deviation theory to our large deviation upper bound obtained in section 5.

**Corollary 6.1.** Let \(\nu_{N,T}\) be the marginal probability distribution on \(U(N)\) of the \(N \times N\) left unitary Brownian motion at time \(T > 0\). Define
\[
I^\text{lib}_{\sigma_0,T}(\sigma) := \inf \{I^\text{lib}_{\sigma_0}(\tau) \mid \pi^*_T(\tau) = \sigma\}, \quad \sigma \in TS(C^*_R(x_{\infty})).
\]
Then for any closed subset \(A\) of \(TS(C^*_R(x_{\infty}))\) we have
\[
\lim_{N \to \infty} \frac{1}{N^2} \log \nu_{N,T}^{\otimes n}\left(\{U \in U(N)^n \mid \text{tr}_{U}^{\Xi(N)} \in A\}\right) \leq -\inf \{I^\text{lib}_{\sigma_0,T}(\sigma) \mid \sigma \in A\}.
\]

Here, \(\text{tr}_{U}^{\Xi(N)} \in TS(C^*_R(x_{\infty}))\) with \(U = (U_i)_{i=1}^{n} \in U(N)^n\) is defined by \(\text{tr}_{U}^{\Xi(N)}(P) := \text{tr}_{N}(\Phi_{U}(P)), P \in \mathbb{C}(x_{\infty})\), where \(\Phi_{U} : \mathbb{C}(x_{\infty}) \to M_N(\mathbb{C})\) is a unique *-homomorphism sending \(x_{ij}\) (1 \(\leq i \leq n\)) to \(U_i x_{ij}(N) U_i^{*}\) and \(x_{n+1,j}\) to \(\xi_{n+1,j}(N)\).

We write
\[
\chi^T_{\text{orb}}(\sigma) := \lim_{\delta \searrow 0} \lim_{N \to \infty} \frac{1}{N^2} \log \nu_{N,T}^{\otimes n}\left(\{U \in U(N)^n \mid \text{tr}_{U}^{\Xi(N)} \in \mathcal{O}_{m,\delta}(\sigma)\}\right),
\]
where \(\mathcal{O}_{m,\delta}(\sigma), m \in \mathbb{N}, \delta > 0\), denotes the (open) subset of \(\sigma' \in TS(C^*_R(x_{\infty}))\) such that \(|\sigma'(x_{i_1,j_1} \cdots x_{i_p,j_p}) - \sigma(x_{i_1,j_1} \cdots x_{i_p,j_p})| < \delta\) whenever 1 \(\leq i_k \leq n+1, 1 \leq j_k \leq r(i_k), 1 \leq k \leq p\) and 1 \(\leq p \leq m\).
A problem in this direction is to show that $\chi_{\text{orb}}(\sigma) \leq \lim_{T \to +\infty} \chi_{\text{orb}}^{T}(\sigma)$ holds, where $\chi_{\text{orb}}(\sigma)$ denotes the orbital free entropy of the random multi-variables $(x_{ij})_{1 \leq j \leq r(i)}$, $1 \leq i \leq n$, under $\sigma$ (see [8],[19]). If this was the case, then we would obtain that $\chi_{\text{orb}}(\sigma) = \lim_{T \to +\infty} \chi_{\text{orb}}^{T}(\sigma)$ (see below) and $\chi_{\text{orb}}(\sigma) \leq -\lim_{T \to +\infty} I_{\sigma_{0},T}^{\text{lib}}(\sigma)$. Remark that, if the families $\{x_{ij}\}_{1 \leq j \leq r(i)}$, $1 \leq i \leq n$, are freely independent under $\sigma_{0}$, then it is easy to see that $\pi_{r}^{T}(\sigma_{0}) = \sigma_{0}$ for all $T \geq 0$, and hence Proposition 5.7(3) shows that $I_{\sigma_{0},T}^{\text{lib}}(\sigma_{0}) = 0$ for all $T \geq 0$ so that $\chi_{\text{orb}}(\sigma_{0}) = -I_{\sigma_{0},T}^{\text{lib}}(\sigma_{0})$ holds as $0 = 0$ for all $T \geq 0$. Thus our conjecture seems plausible.

Here we would like to point out that
\[
\lim_{T \to +\infty} \lim_{N \to \infty} \frac{1}{N^2} \log \max \left\{ \frac{d\nu_{N,T}}{d\nu_{N}}(U) \mid U \in U(N) \right\} = \lim_{T \to +\infty} \lim_{N \to \infty} \frac{1}{N^2} \log \frac{d\nu_{N,T}}{d\nu_{N}}(I_{N}) = 0
\]
with the Haar probability measure $\nu_{N}$ on $U(N)$ follows from the formula obtained precisely by Lévy and Maida [14, Proposition 4.2; Lemma 4.7; Proposition 5.2] with the aid of the fact that
\[
K(k) = \int_{0}^{1} \frac{ds}{\sqrt{(1 - s^2)(1 - k^2s^2)}} = -\frac{1}{2} \log(1 - k) + \frac{3}{2} \log 2 + o(1) \quad (k \nearrow 1).
\]
Thus, for any Borel subset $\Lambda$ of $T S(C_{b}(x_{\bullet}))$ we have
\[
\frac{1}{N^2} \log \nu_{N,T}^{\otimes n}(\left\{ U \in U(N)^{n} \mid \text{tr}_{U}^{\otimes (N)}(U) \in \Lambda \right\}) \leq \frac{1}{N^2} \log \nu_{N,T}^{\otimes n}(\left\{ U \in U(N)^{n} \mid \text{tr}_{U}^{\otimes (N)}(U) \in \Lambda \right\}) + \frac{n}{N^2} \log \frac{d\nu_{N,T}}{d\nu_{N}}(I_{N}),
\]
implying that $\lim_{T \to \infty} \chi_{\text{orb}}^{T}(\sigma) \leq \chi_{\text{orb}}(\sigma)$ (use [20, Remark 3.3] at this point). On the other hand, with
\[
L := \lim_{T \to +\infty} \lim_{N \to \infty} \frac{1}{N^2} \log \min \left\{ \frac{d\nu_{N,T}}{d\nu_{N}}(U) \mid U \in U(N) \right\} (\leq 0),
\]
a similar consideration as above shows that $\lim_{T \to \infty} \chi^{T}_{\text{orb}}(\sigma) \geq \chi_{\text{orb}}(\sigma) + nL$. Hence the problem is whether $L = 0$ or not. We have confirmed this in the affirmative too, and will give a further study on the orbital free entropy in a subsequent paper.

ACKNOWLEDGEMENT

We would like to express our sincere gratitude to the referee for his/her very careful reading of this paper and pointing out a mistake in the original proof of exponential tightness.
