Abstract

We consider the symmetric simple exclusion process on $\mathbb{Z}^d$, for $d \geq 5$, and study the regularity of the quasi-stationary measures of the dynamics conditioned on not occupying the origin. For each $\rho \in ]0,1[$, we establish uniqueness of the density of quasi-stationary measures in $L^2(d\nu_\rho)$, where $\nu_\rho$ is the stationary measure of density $\rho$. This, in turn, permits us to obtain sharp estimates for $P_{\nu_\rho}(\tau > t)$, where $\tau$ is the first time the origin is occupied.

Keywords and phrases: quasi-stationary measures, exchange processes, hitting time, Yaglom limit.

AMS 2000 subject classification numbers: 60K35, 82C22, 60J25.

Running head: Regularity of quasi-stationary measures

1 Introduction

Let $\{\eta_t : t \geq 0\}$ be the symmetric simple exclusion process on $\mathbb{Z}^d$. In this process, there is at most one particle per site (i.e. the state space is $\Omega := \{0,1\}^{\mathbb{Z}^d}$), and at rate one the contents of neighboring sites are interchanged. The homogeneous Bernoulli product measures, say $\nu_\rho$, with density $\rho \in [0,1]$, are invariant and reversible for this process. Let $\tau$ be the first time the origin of $\mathbb{Z}^d$ is occupied by a particle. We are interested in two issues: (i) to estimate the
probability that the origin remains empty for large time when the initial configurations are
drawn from \( \nu \) for each \( \rho \in ]0, 1[ \); (ii) to describe the law of \( \eta_t \), at large time \( t \), conditioned
on \( \{ \tau > t \} \), the event that the origin is empty up to time \( t \).

When the dimension of the lattice is larger than 4, we show that there exists a measure
\( \mu_\rho \), such that for any continuous function \( f \)
\[
\lim_{t \to \infty} E_{\nu_\rho}[f(\eta_t)|\tau > t] = \int f \, d\mu_\rho. \tag{1.1}
\]
This establishes the so-called Yaglom limit \([14]\). Such limiting measures can be intrinsically
characterized as fixed points of the semi-groups \( \{ T_t, t > 0 \} \) defined by
\[
(T_t(\mu), f) := E_\mu[f(\eta_t)|\tau > t], \quad t > 0. \tag{1.2}
\]
Thus, fixed points of \( \{ T_t, t > 0 \} \) are dubbed quasi-stationary measures \([12], [6]\). Here, we
study the regularity of \( \mu_\rho \) and uniqueness when the dimension \( d > 4 \). This, in turn, gives us
sharp asymptotics for the probability of \( P_{\nu_\rho}(\tau > t) \), namely
\[
\lim_{t \to \infty} \frac{\exp(-\lambda(\rho) t)}{P_{\nu_\rho}(\tau > t)} = \int \left( \frac{d\mu_\rho}{d\nu_\rho} \right)^2 \, d\nu_\rho < \infty, \tag{1.3}
\]
where \(-\lambda(\rho) < 0\) is the top of the spectrum in \( L^2(\nu_\rho) \) of \( \bar{L} \), the generator of the simple
exclusion process absorbed when hitting \( \{ \eta : \eta_0 = 1 \} \).

We briefly summarize some relevant results of \([4]\). In dimensions 1 and 2, the Yaglom
limit is \( \delta_0 \), the measure concentrated on the configuration with no particle (and \( \lambda(\rho) = 0 \)). In
dimensions 3 and 4, \( \lambda(\rho) > 0 \) for \( \rho \in ]0, 1[ \), and \( \int_0^t T_s(\nu_\rho) \, ds/t \) converges to a quasi-stationary
measure \( \mu_\rho \). By analogy with the case of independent random walks \([4]\), we conjecture that
the Yaglom limit exists and that \( \mu_\rho \) is singular with respect to \( \nu_\rho \). Thus, it is only for
dimensions larger than 4 that we expect regularity of \( \mu_\rho \) with respect to \( \nu_\rho \).

2 Notations and Results

Henceforth, we consider dimensions larger or equal to 5, and \( \rho \in ]0, 1[ \). The symmetric simple
exclusion process (SSEP) on the lattice \( \mathbb{Z}^d \) can be graphically constructed “à la Harris” \([4]\)
as follows. First, fix the initial configuration by assigning to each site of \( \mathbb{Z}^d \) a value in \( \{ 0, 1 \} \)
which indicates if the site is occupied or empty. Then, to each bond –pairs of adjacent
sites– associate a Poisson processes of intensity 1; Poisson processes of different bonds are
independent and independent of the initial configuration. At the times events (marks) of
each Poisson process, the values of the corresponding sites are interchanged. In this way,
each particle jumps when a mark is present; two particles may jump at the same time in
opposite directions. By labeling particles, we can trace in time their trajectories: they evolve
as the so-called stirring particles. This construction is described in Arratia \([2]\). When the
labels of the stirring particles are disregarded one obtains only the occupation numbers; in
this case the resulting process, called \( \eta_t \), has infinitesimal generator
\[
L f(\eta) = \sum_{i \in \mathbb{Z}^d} \sum_{j : j \sim i} [f(\eta^{i,j}) - f(\eta)], \quad \text{for } \eta \in \{ 0, 1 \}^{\mathbb{Z}^d},
\]
where $\eta_k^{ij} = \eta_k + (\delta_{kj} - \delta_{ki})(\eta_i - \eta_j)$ and $i \sim j$ means that $|i_1 - j_1| + \cdots + |i_d - j_d| = 1$. It is well known that the process is Feller, and the product measures of density $\rho$ in $[0,1]$, say $\nu_{\rho}$, are reversible for $L$ (see Chapter VIII of Liggett [1]). In other words, $L$ is an unbounded self-adjoint operator in $L^2(d\nu_{\rho})$, and local functions form a core for the domain, say $D(L)$. We denote by $P_{\nu_{\rho}}$ the law of the SSEP with initial measure $\nu_{\rho}$. Let $\mathcal{A} = \{\eta : \eta_0 = 1\}$ and denote by $\tau$ the time of first occurrence of $\mathcal{A}$. As we are interested in the Dirichlet problem on $\mathcal{A}^c$, we introduce $\mathcal{H}_\mathcal{A} = \{\varphi \in L^2(\nu_{\rho}) : \varphi(\eta) = 0$ for $\eta \in \mathcal{A}\}$. Let $\bar{L}$ be the operator defined by

$$\bar{L}f = 1_{\mathcal{A}^c}Lf, \quad \text{for } f \in D(L) \cap \mathcal{H}_\mathcal{A}.$$ 

This corresponds to the simple exclusion dynamics absorbed when hitting the event $\mathcal{A}$. $\bar{L}$ is self-adjoint on $\mathcal{H}_\mathcal{A}$ with respect to $\nu_{\rho}$. We call $\{S_t, t > 0\}$ the corresponding sub-Markovian semi-group of bounded operators on $L^2(\mathcal{H}_\mathcal{A}, \nu_{\rho})$. In other words,

$$\forall t > 0, \quad \bar{S}_t f(\eta) = E^n[f(\eta_t)|\tau > t].$$

We denote by $T_t(\nu_{\rho})$ the probability measure defined by duality on $\varphi \in \mathcal{H}_\mathcal{A}$,

$$(T_t(\nu_{\rho}), \varphi) = \int \bar{S}_t \varphi 1_{\mathcal{A}^c} d\nu_{\rho} = \int \varphi \frac{\bar{S}_t 1_{\mathcal{A}^c}}{P_{\nu_{\rho}}(\tau > t)} d\nu_{\rho},$$

where we have used reversibility to obtain the third term. Thus, if $f_t$ is the density of $T_t(\nu_{\rho})$ with respect to $\nu_{\rho}$

$$\forall t > 0, \quad f_t(\eta) = \frac{\bar{S}_t 1_{\mathcal{A}^c}(\eta)}{P_{\nu_{\rho}}(\tau > t)} = \frac{P^n(\tau > t)}{\int P^c(\tau > t) d\nu_{\rho}(\zeta)}. \quad (2.1)$$

It was established in [1] that a non-trivial quasi-stationary measure, say $\mu_{\rho}$, could be obtained as limit along a Cesàro subsequence of $T_t(\nu_{\rho})$. Our main result is the following theorem.

**Theorem 2.1** If the dimension is larger or equal to 5, then $\mu_{\rho}$ is absolutely continuous with respect to $\nu_{\rho}$. Moreover, for any integer $k \geq 1$, $d\mu_{\rho}/d\nu_{\rho} \in L^k(\nu_{\rho})$ and

$$\lim_{t \to \infty} \int \left( \frac{dT_t(\nu_{\rho})}{d\nu_{\rho}} - \frac{d\mu_{\rho}}{d\nu_{\rho}} \right)^2 d\nu_{\rho} = 0. \quad (2.2)$$

**Remark 2.2** This is stronger than establishing the Yaglom limit, i.e. $\lim T_t(\nu_{\rho}) = \mu_{\rho}$. As a consequence, $f := d\mu_{\rho}/d\nu_{\rho}$ belongs to $D(\bar{L})$ and satisfies (in the $L^2(\nu_{\rho})$-sense)

$$\bar{L}f + \lambda(\rho)f = 0, \quad \text{and } \bar{S}_t f = e^{-\lambda(\rho)t}f, \quad (2.3)$$

with (see Theorem 2 of [1])

$$\lambda(\rho) = \inf \left\{ \frac{(f, -\bar{L}f)_{\nu_{\rho}}}{(f, f)_{\nu_{\rho}}} : f \in D(L) \cap \mathcal{H}_\mathcal{A} \right\}. \quad (2.4)$$

Theorem 2.1 is based on the apriori bounds through the following lemma, in which we reformulate a general result essentially contained in [1].
Lemma 2.3 Let \( \{\bar{S}_t\} \) be the semi-group of a process absorbed when hitting a set \( A \). Assume that \( \{\bar{S}_t\} \) is reversible with respect to \( \nu \), and let \( \lambda < \infty \) be given by (2.4). The following two conditions are equivalent

\[
(i) \sup_{t>0} \frac{e^{-\lambda t}}{P_\nu(\tau > t)} < \infty, \quad \text{and} \quad (ii) \sup_{t>0} \int f_i^2 d\nu < \infty. \tag{2.5}
\]

Moreover, if either (i) or (ii) holds, then the Yaglom limit \( \mu \) exists and (2.2) holds.

Now, the apriori bounds is a corollary of the following proposition, interesting on its own.

Proposition 2.4 Let the dimension \( d \geq 3 \). Let \( i \in \mathbb{Z}^d \setminus \{0\} \) and \( \eta \in \Omega \) with \( \eta_i = 0 \). We denote by \( \eta^i \) the configuration identical to \( \eta \) except on \( i \), where its value is 1. There is a constant \( C_d \), independent of \( i \) and \( \eta \), such that for any \( t > 0 \),

\[
0 \leq P^n(\tau > t) - P^{\eta^i}(\tau > t) \leq C_d P^{\eta^i}(\tau > t) \mathbb{P}(H_i < \infty), \tag{2.6}
\]

where \( H_i \) denotes the first time a symmetric random walk starting at \( i \) hits the origin.

The relation (2.6) would be obvious if the particles were independent. Though it is rather intuitive for the symmetric exclusion, our proof is rather long. A sketch of it is as follows. We first write \( P^n(\tau > t) \) in terms of a dual process, say \( \{X(\emptyset, t)\} \), which corresponds to a stirring process on \( \mathbb{Z}^d \setminus \{0\} \) with birth at the nearest neighbors of the origin and with initial condition an empty configuration. Then, \( P^n(\tau > t) - P^{\eta^i}(\tau > t) \) corresponds to the weight of all paths whose end-points \( X(\emptyset, t) = U \cup \{i\} \) with \( \eta_j = 0 \) for all \( j \in U \subset \mathbb{Z}^d \setminus \{0, i\} \). The problem is then to uncouple \( U \) from \( \{i\} \). We then re-express \( P(X(\emptyset, t) = U \cup \{i\}) \) in terms of a dual with finitely many particles, say \( \{\Lambda_t\} \). Note that \( \{\Lambda_t\} \) is not the ‘natural dual’ of \( \{X(\emptyset, t)\} \) and the correspondence is obtained through a Feynman-Kac formula. Then we show a correlation inequality for the expression in terms of \( \{\Lambda_t\} \) by generalizing Andjel’s inequality [1].

The results about apriori bounds is the following.

Corollary 2.5 Let the dimension \( d \geq 5 \). (i) There is a product measure \( \nu_\alpha(\cdot) \) of density \( \alpha(i) \) for \( i \in \mathbb{Z}^d \) such that for any \( t > 0 \)

\[
\nu_\alpha(\cdot) \prec T_t(\nu_\rho) \prec \nu_\rho, \quad \text{and} \quad \sum_{i \in \mathbb{Z}^d} (1 - \frac{\alpha_i}{\rho})^2 < \infty,
\]

where \( \prec \) denotes stochastic domination.

(ii) For any integer \( k \geq 1 \), there is a positive constant \( C \), such that

\[
\sup_{t>0} \int f_i^k(\eta) d\nu_\rho(\eta) \leq C. \tag{2.7}
\]

A consequence of Lemma 2.3 is a sharp asymptotic estimate for the tail of \( \tau \) (compare with [4] Lemma 1).
Corollary 2.6  If the dimension $d \geq 5$, then
\[
\lim_{t \to \infty} e^{-\lambda(\rho)t} P_{\nu_\rho}(\tau > t) = \int f^2 d\nu_\rho.
\] (2.8)

Finally, we have a uniqueness result and some properties of $\mu_\rho$.

Theorem 2.7  (i) The set $\{\mu \ll \nu_\rho : \mu$ is quasi stationary and $d\mu/d\nu_\rho \in L^2(\nu_\rho)\}$ contains only $\mu_\rho$.  (ii) For $i \in \mathbb{Z}^d$, define $\theta_i : \Omega \to \Omega$ with $\theta_i \eta_k = \eta_{k+i}$, then for any $\varphi$ local (i.e. depending on finitely many sites)
\[
\lim_{||i|| \to \infty} \int \varphi(\theta_i \eta)d\mu_\rho(\eta) = \int \varphi d\nu_\rho.
\]
(iii) If $\nu$ is a probability with a continuous density with respect to $\nu_\rho$, then
\[
\lim_{t \to \infty} \frac{1}{t} \int_0^t T_s(\nu)ds = \mu_\rho.
\]
The convergence holds in weak-$L^2(\nu_\rho)$.

Proposition 2.4 is proven in Section 3. Section 4 contains the proofs of Corollary 2.5 and of Theorem 2.7. In section 5, we establish the uniqueness part of Theorem 2.7. In section 6, we show that in $\mu_\rho$ the density at infinity is $\rho$, and we conclude with the result about the basin of attraction of $\mu_\rho$.

3  Proof of Proposition 2.4.

3.1  Duality and Feynman-Kac.

We first express $P^n(\tau > t)$ using the dual process ([1], [2]) based on the fact that the Poisson clocks associated to bonds are invariant by time reflections. The dual process tracing back-in-time the positions of the stirring particles touching the origin can be described using the graphical construction at the beginning of Section 2. Again at each bond, there is an independent mark process corresponding to the realization of a Poisson process of intensity 1. At each bond between 0 and one of its nearest neighbor, say $i$, a particle is born at $i$ unless $i$ is already occupied (in which case nothing happens); the particles born in this way evolve afterwards as stirring particles on $\mathbb{Z}^d \setminus \{0\}$. The only difference with the previous construction is that now it is imposed to the origin to be occupied at all times — so that when it becomes empty, it is immediately occupied with a newly created particle. Assume that at time 0, the lattice is empty and let $X(\emptyset, t)$ be the set of sites occupied by the stirring particles at time $t$; all these particles have been created at the origin. Let $\mathbb{P}$ denote averages over the Poisson realizations. If $\mathcal{P}^*$ is the collection of finite subsets of $\mathbb{Z}^d \setminus \{0\}$, then the duality formula reads for any $t > 0$
\[
P^n(\tau > t) = (1 - \eta_0) \sum_{\Lambda \in \mathcal{P}^*} \mathbb{P}(X(\emptyset, t) = \Lambda) \prod_{j \in \Lambda} (1 - \eta_j).
\] (3.1)
Thus, if $\eta$ is such that $\eta_i = 0$

$$P^n(\tau > t) - P^n(\tau > t) = (1 - \eta_0) \sum_{\Lambda \in \mathcal{P}^*, \Lambda \ni i} \mathbb{P} (X(\emptyset, t) = \Lambda) \prod_{j \in \Lambda} (1 - \eta_j).$$

Assume, for a moment, that for $U \in \mathcal{P}^*$ and $i \not\in U$, we have a constant $C_d$ independent of $i$ and $t$ such that

$$\mathbb{P} (X(\emptyset, t) = U \cup \{i\}) \leq C_d \mathbb{P} (X(\emptyset, t) = U) \mathbb{P} (H_i < \infty),$$

where we denote by $H_i$ the first time a symmetric random walk starting at $i$ hits the origin. Then, for $\eta$ such that $\eta_i = 0$

$$P^n(\tau > t) - P^n(\tau > t) \leq C_d \mathbb{P} (H_i < \infty)(1 - \eta_0) \sum_{U \in \mathcal{P}^*, i \not\in U} \mathbb{P} (X(\emptyset, t) = U) \prod_{j \in U \cup \{i\}} (1 - \eta_j)$$

$$\leq C_d (1 - \eta_i) \mathbb{P} (H_i < \infty) P^n(\tau > t).$$

Thus, it remains to prove (3.2).

Let $\mathcal{L}^+$ be the generator of $\{X(\emptyset, t), t \geq 0\}$, and let $S^+_i$ be the associated semi-group. We first express the dual of $\{X(\emptyset, t), t \geq 0\}$ in terms of a process with finitely many particles. Actually, we are only interested in $S^+_i(1_{\Lambda})(\emptyset) := \mathbb{P}(X(\emptyset, t) = \Lambda)$ for $\Lambda \in \mathcal{P}^*$. Let $\Lambda$ and $A$ be in $\mathcal{P}^*$. We have, using $\Delta$ for the symmetric difference,

$$\mathcal{L}^+(1_{\Lambda})(A) = \sum_{\substack{x \sim y; x, y \not\in \{0\} \\
|A \Delta \{x, y\}| = |A|}} [1_{\Lambda}(A \Delta \{x, y\}) - 1_{\Lambda}(A)] + \sum_{\substack{y \sim 0 \\
y \not\in A}} [1_{\Lambda}(A \cup \{y\}) - 1_{\Lambda}(A)].$$

The first sum corresponds to the stirring process over $\mathbb{Z}^d \setminus \{0\}$, while the second sum corresponds to birth at the origin. We reexpress now the last sum. For simplicity, we omit to write $y \sim 0$. Thus,

$$\sum_{y \not\in A} [1_{\Lambda}(A \cup \{y\}) - 1_{\Lambda}(A)] - \sum_{y \not\in A} [1_{\Lambda}(A \cup \{y\}) - 1_{\Lambda}(A)] - \sum_{y \not\in A} 1_{\Lambda}(A).$$

We claim that this expression is equal to

$$\mathcal{C} := \sum_{y \in \Lambda} [1_{\Lambda}(\Lambda \setminus \{y\}) - 1_{\Lambda}(\Lambda)] - \sum_{y \not\in \Lambda} 1_{\Lambda}(\Lambda) + \sum_{y \in \Lambda} 1_{\Lambda}(\Lambda).$$

Indeed, we expand $\mathcal{C}$

$$\mathcal{C} = \sum_{\substack{y \in \Lambda \\
y \not\in A}} [1_{\Lambda}(\Lambda \setminus \{y\}) - 1_{\Lambda}(\Lambda)] + \sum_{\substack{y \in \Lambda \\
y \not\in A}} [1_{\Lambda}(\Lambda \setminus \{y\}) - 1_{\Lambda}(\Lambda)] - \sum_{y \not\in A} 1_{\Lambda}(\Lambda) + \sum_{y \in \Lambda} 1_{\Lambda}(\Lambda)$$

$$= \sum_{y \not\in A} [1_{\Lambda}(\Lambda \setminus \{y\}) - 1_{\Lambda}(\Lambda)] - \sum_{y \not\in A} 1_{\Lambda}(\Lambda).$$
Thus, calling \( \mathcal{N}_0 := \{ y \in \mathbb{Z}^d : y \sim 0 \} \) and using the self-duality of the stirring part of \( \mathcal{L}^+ \), we obtain
\[
\mathcal{L}^+(1_\Lambda)(A) = \sum_{x \sim y: x, y \neq \emptyset} [1_A(\Lambda \Delta \{x, y\} - 1_A(\Lambda)) + \sum_{y \sim 0} [1_A(\Lambda \setminus \{y\}) - 1_A(\Lambda)] + V(\Lambda)1_A(\Lambda).
\]
where we set \( V(\Lambda) := 2|\mathcal{N}_0 \cap \Lambda| - |\mathcal{N}_0| \). Now, let \( \mathcal{L}^- \) denote the generator of the stirring process on \( \mathbb{Z}^d \setminus \{0\} \) with death when particles jump on the origin. Then, (3.3) can be written like
\[
\mathcal{L}^+(1_\Lambda)(A) = \mathcal{L}^-(1_\Lambda)(A) + V(\Lambda)1_A(\Lambda).
\]
Thus, if \( u(\Lambda, t) := S_t^+(1_\Lambda)(\emptyset) \), we have
\[
\frac{du(\Lambda, t)}{dt} = S_t^\ast(\mathcal{L}^+1_\Lambda)(\emptyset) = \mathcal{L}^-u(\Lambda, t) + V(\Lambda)u(\Lambda, t).
\]
Now, we call \( \{\Lambda(t), t \geq 0\} \) the process generated by \( \mathcal{L}^- \) and we use Feynman-Kac to obtain
\[
\mathbb{P}(X(\emptyset, t) = \Lambda) = \mathbb{E}^\Lambda[\exp(\int_0^t V(\Lambda(s))ds)1_\emptyset(\Lambda(t))] = e^{-\int_0^t |\mathcal{N}_0\cap \Lambda(s)|ds)1_\emptyset(\Lambda(t))}.
\]
Let now \( U \in \mathcal{P}^* \) and \( i \notin U \). We show in section 3.2 that if \( \Lambda \in \mathcal{P}^* \) and
\[
g(\Lambda, t) := \mathbb{E}^\Lambda[\exp(2 \int_0^t |\mathcal{N}_0\cap \Lambda(s)|ds)1_\emptyset(\Lambda(t))], \quad \text{then} \quad g(U \cup \{i\}, t) \leq g(U, t)g(\{i\}, t). \quad (3.4)
\]
Then, in section 3.3 we prove that \( g(\{i\}, t) \leq C_d P(H_i < \infty) \) for \( d \geq 3 \). Inequality (3.2) follows then readily.

### 3.2 A generalized correlation inequality.

To make the notations closer to those of Andjel [1], we set \( p(x, y) = 1 \) when \( x \sim y \), and \( p(x, y) = 0 \) otherwise. Also, we realize our stirring process as an exclusion process: the particles attempt to jump to one of their nearest neighboring sites at the time marks of independent Poisson processes of intensity \( 2d \); if the site chosen (each neighboring site is chosen with the same probability) for the attempt is occupied, the particle stays still. As we are blind to the labeling of particles, the trajectories are, in law, indistinguishable from our initial stirring process.

We proceed by induction on \( n \) to prove that for any sets \( A, B \in \mathcal{P}^* \), with \( A \cap B = \emptyset \), for any \( t > 0 \), \( \alpha \in \mathbb{R} \), and any \( n \)-tuples \( 0 \leq s^1 < s^2 < \cdots < s^n \leq t \), the following inequality holds
\[
\mathbb{E}^{A \cup B}[e^{\alpha \sum_{k=1}^n |\mathcal{N}_0 \cap \Lambda(s^k)|}1_\emptyset(\Lambda(t))] \leq \mathbb{E}^A[e^{\alpha \sum_{k=1}^n |\mathcal{N}_0 \cap \Lambda(s^k)|}1_\emptyset(\Lambda(t))] \mathbb{E}^B[e^{\alpha \sum_{k=1}^n |\mathcal{N}_0 \cap \Lambda(s^k)|}1_\emptyset(\Lambda(t))].
\]
(3.5)
This will be our induction hypothesis at order \( n \). Once (3.3) is proved, inequality (3.4) follows easily as in Proposition 4.1 of [3].
Step n=0. We need to prove that for \( A, B \in \mathcal{P}^* \) with \( A \cap B = \emptyset \)

\[
P^{A \cup B}(\Lambda(t) = \emptyset) \leq P^A(\Lambda(t) = \emptyset)P^B(\Lambda(t) = \emptyset).
\]

(3.6)

Following an idea of Arratia [3], we represent the process \( \Lambda(t) \) as limit of a stirring process with no absorption on an enlarged lattice: we link the origin 0 with \( \hat{0} \) the origin of a three dimensional lattice \( \hat{Z}^3 \) isomorphic to \( Z^3 \) (here we fix \( Z^3 \) for concreteness; any graph supporting the stirring construction, for which the corresponding random walk is transient would fit). On each bond of \( \hat{Z}^3 \) and on the bond \((0, \hat{0})\), the rates of stirring are set equal to \( \kappa \) large. On the enlarged lattice \( \hat{Z}^3 \), the particles perform a conservative stirring process, though with different rates whether they jump across the bonds of \( \hat{Z}^3 \) or across the bonds of \( \hat{Z}^3 \) and \((0, \hat{0})\). When a particle hits the origin 0, it has a probability going to 1 as \( \kappa \to \infty \) to wander in \( \hat{Z}^3 \) up to time \( t \) without using bonds of \( \hat{Z}^3 \). We call \( U(t) \) the stirring process on \( Z^d \cup \hat{Z}^3 \), and \( \mathbb{P}_\kappa \) the law of the Poisson marks on the enlarged lattice. It is not difficult to show that for any \( \Lambda \in \mathcal{P}^* \),

\[
P^A(\Lambda(t) = \emptyset) = \lim_{\kappa \to \infty} \mathbb{P}_\kappa^A(U(t) \subset \hat{Z}^3).
\]

(3.7)

Now, for the stirring process on the enlarged lattice \( Z^d \cup \hat{Z}^3 \), we use a correlation inequality due to Andjel [1]:

\[
P^A_{\kappa^{A \cup B}}(U(t) \subset \hat{Z}^3) \leq \mathbb{P}^A(U(t) \subset \hat{Z}^3) \mathbb{P}^B(U(t) \subset \hat{Z}^3).
\]

(3.8)

Thus, after taking the limit \( \kappa \to \infty \), we obtain (3.6).

Step n. Our proof follows essentially Andjel’s proof. Our induction hypothesis is that (3.3) is valid for \( n-1 \) instants of time. Let \( 0 \leq s^1 < s^2 < \cdots < s^n \leq t \) be \( n \) instants of time, and for each \( \Lambda \in \mathcal{P}^* \) let

\[
g_n(\Lambda, t; s^1, \ldots, s^n) = E^A[\exp(\alpha \sum_{i=1}^{n} |\mathcal{N}_0 \cap \Lambda(s^i)|)1_0(\Lambda(t))].
\]

We set \( \lambda = 2d(|A| + |B|) \) and we let \( \tau_1 \) be the first time a particle of \( A \cup B \) attempts a jump (i.e. \( \tau_1 \) is an exponential time of parameter \( \lambda \)). Note that by the Markov property

\[
E^{A \cup B}[\exp(\alpha \sum_{i=1}^{n} |\mathcal{N}_0 \cap \Lambda(s^i)|)1_0(\Lambda(t))1_{\{\tau_1 > s^1\}}]
\]

\[
= P(\tau_1 > s^1)e^{\alpha(|A \cap \mathcal{N}_0| + |B \cap \mathcal{N}_0|)}E^{A \cup B}[\exp(\alpha \sum_{i=2}^{n} |\mathcal{N}_0 \cap \Lambda(s^i - s^1)|)1_0(\Lambda(t - s^1))]
\]

\[
= P(\tau_1 > s^1)e^{\alpha(|A \cap \mathcal{N}_0| + |B \cap \mathcal{N}_0|)}g_{n-1}(A \cup B, t - s^1, s^2 - s^1, \ldots, s^n - s^1).
\]

Following [1], using the shorthand notation \( s \) for \( s^1, \ldots, s^n \) (and its abuse \( s - u = (s^1 - u, \ldots, s^n - u) \)), and writing \( A\Delta\{x, y\} \) to mean \( A\Delta\{x, y\}\setminus\{0\} \), for we have to account for
deaths of particles when they jump on 0, we have
\[
g_n(A \cup B, t; s) = P(\tau_1 > s^1)e^{\alpha|A|\lambda_0}e^{\alpha|B\cap N_0|}g_{n-1}(A \cup B, t - s^1; s^2 - s^1, \ldots, s^n - s^1) \\
+ \int_0^{s^1} du \lambda e^{-\lambda u} \frac{1}{\lambda} \left\{ \sum_{x,y \in A} p(x, y) + \sum_{x,y \in B} p(x, y) \right\} g_n(A \cup B, t - u; s - u) \\
+ \left[ \sum_{x \in A, y \not\in A \cup B} p(x, y) g_n(A \Delta \{x, y\} \cup B, t - u; s - u) \right] \\
+ \left[ \sum_{x \in B, y \not\in A \cup B} p(x, y) g_n(A \cup B \Delta \{x, y\}, t - u; s - u) \right] \\
+ \left\{ \sum_{x \in A, y \not\in B} p(x, y) + \sum_{x \in B, y \not\in A} p(x, y) \right\} g_n(A \cup B, t - u; s - u) \right\}
\]

Reasoning as if the particles in A were independent from the particles in B, we obtain
\[
g_n(A, t; s)g_n(B, t; s) = \\
P(\tau_1 > s^1)e^{\alpha|A\cap N_0|}e^{\alpha|B\cap N_0|}g_{n-1}(A, t - s^1; s^2 - s^1, \ldots, s^n - s^1, \ldots) \\
+ \int_0^{s^1} du \lambda e^{-\lambda u} \frac{1}{\lambda} \left\{ \sum_{x,y \in A} p(x, y) + \sum_{x,y \in B} p(x, y) \right\} g_n(A, t - u; s - u) g_n(B, t - u; s - u) \\
+ \left[ \sum_{x \in A, y \not\in A \cup B} p(x, y) g_n(A \Delta \{x, y\} \cup B, t - u; s - u) \right] \\
+ \left[ \sum_{x \in B, y \not\in A \cup B} p(x, y) g_n(A \cup B \Delta \{x, y\}, t - u; s - u) \right] \\
+ \left\{ \sum_{x \in A, y \not\in B} p(x, y) + \sum_{x \in B, y \not\in A} p(x, y) \right\} g_n(A \cup B, t - u; s - u) \right\}.
\]

Define
\[
G_n(t) = \sup_{0 \leq s^1 < \ldots < s^n \leq t} \sup_{C \cap D = \emptyset} g_n(C \cup D, t; s) - g_n(C, t; s)g_n(D, t; s),
\]
also set \( F_n(t) = \sup \{ G_n(s) : 0 \leq s \leq t \} \). Now, the key observation of Andjel, in [1] p. 720, is that for \( x \in A \) and \( y \in B \) (so that both \( x, y \neq 0 \))
\[
g_n(A \cup B, t; s) \leq F_n(t) + \frac{1}{2} \left( g_n(A, t; s)g_n(B \Delta \{x, y\}, t; s) + g_n(A \Delta \{x, y\}, t; s)g_n(B, t; s) \right).
\]
Thus, using the induction hypothesis \((F_{n-1} = 0)\) and the symmetry of \(p(.,.)\), we obtain

\[
g_n(A \cup B, t; s) - g_n(A, t; s)g_n(B, t; s)
\leq \int_0^s e^{-\lambda u} \left[ \sum_{x,y \in A} p(x, y) + \sum_{x \in A, y \notin A \cup B} p(x, y) + \sum_{x \in B, y \notin A \cup B} p(x, y) + 2 \sum_{x \in A} p(x, y) \right] F_n(t - u) du
\leq \int_0^s e^{-\lambda u} \lambda F_n(t - u) du \leq F_n(t) \int_0^t \lambda e^{-\lambda u} du.
\]

Thus, by taking the supremum over \(A, B \in \mathcal{P}^*\) with \(A \cap B = \emptyset\), we obtain \(G_n(t) \leq F_n(t) \int_0^t \lambda \exp(-\lambda u) du\). Finally, this implies that \(F_n(t) = 0\), and the proof is completed.

\[\boxrule 0.5em \boxit{\textbf{3.3 Upper bound} } g(\{i\}, t) \leq C_d \mathbb{P}(H_1 < \infty).\]

We first use the classical representation of the trajectories \(\{\Lambda(\{i\}, t), t > 0\}\) as sequences of jump times \(\{\tau_i, i \in \mathbb{N}\}\), which are independent exponential variables of parameter \(2d\), associated with the paths of a simple symmetric random walk killed at the origin, say \(\{\Lambda_i, i \in \mathbb{N}\}\). The processes \(\{\Lambda_i, i \in \mathbb{N}\}\) and \(\{\tau_j, j \in \mathbb{N}\}\) are independent. We use the notation \(E^y\) and \(P^y\) to denote average over paths of \(\{\Lambda_i, i \in \mathbb{N}\}\) starting on \(y\). Let \(T_0 = \inf\{n > 0 : \Lambda_n \in \mathcal{N}_y\}\) with \(\mathcal{N}_0 = \{y : y \sim 0\}\). When \(T_0 < \infty\), let \(T_1\) be the first return time to \(\mathcal{N}_0\), whereas when \(T_0 = \infty\), set \(T_1 = \infty\). Then, the sequence of successive entrance times in \(\mathcal{N}_0\), \(\{T_2, T_3, \ldots\}\) is defined inductively. The number of return to \(\mathcal{N}_0\) is called \(R\), i.e. if \(T_i = \infty\) but \(T_{i-1} < \infty\) then \(R = i\). Our walk on \(\mathbb{Z}_d^d\) being transient, we have \(R < \infty\), a.s. We note also, that by symmetry, for any \(y, y' \in \mathcal{N}_0\)

\[P^y(T_0 < \infty) = P^y(T_0 < \infty) \quad \text{and} \quad \forall k \in \mathbb{N}, \quad P^y(R = k) = P^{y'}(R = k).\]

For convenience, we call \(P^{\mathcal{N}_0}(T_0 < \infty) := P^y(T_0 < \infty)\) and \(P^{\mathcal{N}_0}(R = k) = P^y(R = k)\) for \(y \in \mathcal{N}_0\). Now,

\[
g(\{i\}, t) \leq E^i \left[ 1\{T_0 < \infty\} \exp(2 \sum_{i=0}^R \tau_{T_i}) \right] = \sum_{k=0}^\infty E^i \left[ 1\{T_0 < \infty\} 1\{R=k\} \exp(2 \sum_{i=0}^k \tau_{T_i}) \right]
\]

\[= P^i(T_0 < \infty) \sum_{k=0}^\infty P^{\mathcal{N}_0}(R = k) (E[e^{2\tau_1}])^k. \quad (3.9)\]

where we used the Markov property and induction. Now, by the same arguments

\[P^{\mathcal{N}_0}(R = k) \leq (P^{\mathcal{N}_0}(T_0 < \infty))^k.\]

On the other hand, the evaluation of \(E[\exp(2\tau_1)]\) is easy

\[E[e^{2\tau_1}] = \int_0^\infty e^{2t} 2de^{-2dt} dt = \frac{d}{d+1}. \quad (3.10)\]
Thus, with (3.9) and (3.10), our upper bound follows easily as soon as
\[ P^{N_0}(T_0 < \infty) < \frac{d-1}{d}, \tag{3.11} \]
We want to formulate (3.11) in terms of hitting probabilities for the standard random walk, say \( \{S_n, n \geq 0\} \). We will denote the averages over the standard walk with a tilde. Let \( \kappa = \inf\{n > 0 : S_n = 0\} \), and note first that
\[ \tilde{P}^{N_0}(T_0 < \infty, \kappa > T_0) = \tilde{P}^{N_0}(T_0 < \infty). \]
By conditioning on the first move, we obtain
\[ \tilde{P}^{N_0}(T_0 < \infty) = \frac{1}{2d} + \tilde{P}^{N_0}(T_0 < \infty, \kappa > T_0). \]
Thus, (3.11) is equivalent to
\[ \tilde{P}^{N_0}(T_0 < \infty) < \frac{2d-1}{2d}. \tag{3.12} \]

Thus, in dimension 3, \( \tilde{E}[R] \leq 6(0.52) < 5 \) and our condition (3.11) holds. Thus, in dimension 3, \( \tilde{E}[R] \leq 6(0.52) < 5 \) and our condition (3.11) holds. We conclude that (3.11) holds for any dimension larger or equal to 3 because the right hand side of \( \tilde{E}[R] < 2d-1 \) increases and the average number of visits to 0 decreases with dimensions. As we have not found a reference of this latter fact, we present a short proof due to Andjel. The number of visits to 0 is a geometric random variable of parameter \( P_0(T_0 < \infty) \), so it suffices to show monotonicity for this quantity. Let \( i \) be any neighbor of 0; by symmetry \( a(d) := P_0(T_0 < \infty) = P_i(T_0 < \infty) \).
for dimension \( d \geq 3 \). Project the \( d \)-dimensional walk on a hyperplane orthogonal to \( i' \), a neighbor of the origin different from \( i \). The projected walk on \( \mathbb{Z}^{d-1} \) has transition probabilities \( 1/2d \) to go to each of its \( 2(d - 1) \) neighbors and \( 1/d \) not to move. It is clear that \( a(d) \) is not larger than the probability of visiting the origin starting at (the projection of) \( i \) for the projected walk. This latter probability is actually equal to \( a(d - 1) \). Indeed, the projected process goes along the same trajectories as the \((d - 1)\)-dimensional standard walk and the waiting times at each point are geometric random variables with parameter \((d - 1)/d\): thus, if the trajectory of the standard walk is such that \( \{ T < \infty \} \), then the same holds for the projected walk and vice-versa.

4 Apriori Bounds.

4.1 Proof of Corollary 2.5

(i) The proof proceeds along the same lines as the proof of Theorem 3c) of [4], once the measure \( \nu_{\alpha(\cdot)} \) is defined. We set \( \alpha_0 = 0 \), and for \( i \neq 0 \), let \( \alpha_i \) be defined by

\[
\frac{\alpha_i}{1 - \alpha_i} \frac{1 - \rho}{\rho} = \frac{1}{1 + C_d \mathbb{P}(H_i < \infty)},
\]

where the constant \( C_d \) is that of (2.4). Note that \( 0 < \alpha_i < \rho \). Now, in the proof of Theorem 3c) of [4], we showed that \( \nu_{\alpha(\cdot)} \ll \nu_\rho \) and \( d\nu_{\alpha(\cdot)}/d\nu_\rho \in L^p(\nu_\rho) \) for \( p > 1 \) as soon as

\[
\sum_{i \in \mathbb{Z}^d} (1 - \frac{\alpha_i}{\rho})^2 < \infty, \quad \text{or equivalently in } d \geq 3 \sum_{i \in \mathbb{Z}^d} \mathbb{P}(H_i < \infty)^2 < \infty,
\]

which holds as soon as \( d \geq 5 \).

We rewrite (2.4) on \( \{ \eta : \eta_i = 0 \} \) with \( i \neq 0 \), denoting by \( \sigma_i \) the action of spin flip at site \( i \) (i.e. \( \sigma_i \eta_k = \eta_k \) if \( k \neq i \) and \( \sigma_i \eta_i = 1 - \eta_i \))

\[
\sigma_i f_t \geq \frac{\alpha_i}{1 - \alpha_i} \frac{1 - \rho}{\rho} f_t \quad \text{or equivalently} \quad \sigma_i f_t \frac{d\nu_{\alpha(\cdot)}}{d\nu_\rho} \geq \sigma_i \frac{d\nu_{\alpha(\cdot)}}{d\nu_\rho} f_t. \tag{4.1}
\]

Now, on \( \mathcal{A} \), we form \( \varphi = dT_t(\nu_\rho)/d\nu_{\alpha(\cdot)} \) and we note that \( \varphi \) is increasing. Indeed, if \( i \neq 0 \) and \( \eta_i = 0 \), then (4.1) is nothing but \( \sigma_i \varphi \geq \varphi \). Now, as a product measure \( \nu_{\alpha(\cdot)} \) satisfies FKG. Thus, for \( \psi \) increasing

\[
\int \psi dT_t(\nu_\rho) = \int \psi \frac{dT_t(\nu_\rho)}{d\nu_{\alpha(\cdot)}} d\nu_{\alpha(\cdot)} \geq \int \psi d\nu_{\alpha(\cdot)} \int \frac{dT_t(\nu_\rho)}{d\nu_{\alpha(\cdot)}} d\nu_{\alpha(\cdot)} = \int \psi d\nu_{\alpha(\cdot)}.
\]

Thus, \( \nu_{\alpha(\cdot)} \prec T_t(\nu_\rho) \). The fact that \( T_t(\nu_\rho) \prec \nu_\rho \) comes from the fact that \( f_t \) is decreasing and \( \nu_\rho \) satisfies FKG. Now, (ii) of Corollary 2.5 follows as in the proof of Theorem 3c) of [4]. Using that \( f_t \) and \( d\nu_{\alpha(\cdot)}/d\nu_\rho \) are decreasing, for \( i \geq 1 \) and \( j \geq 0 \),

\[
\int f_t^i \left( \frac{d\nu_{\alpha(\cdot)}}{d\nu_\rho} \right)^j \rho = \int f_t^{i-1} \left( \frac{d\nu_{\alpha(\cdot)}}{d\nu_\rho} \right)^j dT_t(\nu_\rho) \leq \int f_t^{i-1} \left( \frac{d\nu_{\alpha(\cdot)}}{d\nu_\rho} \right)^j d\nu_{\alpha(\cdot)} = \int f_t^{i-1} \left( \frac{d\nu_{\alpha(\cdot)}}{d\nu_\rho} \right)^j d\nu_\rho.
\]
Thus, we obtain by induction, for each $n \geq 1$
\[ \int f^n d\nu_\rho \leq \left( \frac{d\nu_\rho}{d\mu} \right)^n \int d\nu_\rho. \tag{4.2} \]
Since the right hand side of (4.2) is bounded for $d \geq 5$, the corollary follows.

### 4.2 Proof of Lemma 2.3

In [4] section 4, we have that $t \mapsto R(t) := e^{-\lambda t}/P_\nu(\tau > t)$ is increasing and $R(0) > 0$. Suppose (i) and let $\lim_{t \to \infty} R(t) = R < \infty$. Now, (ii) follows from
\[ \int f^2 d\nu = \int \frac{\tilde{S}_t(1_{A^c})\tilde{S}_t(1_{A^c})}{P_\nu(\tau > t)^2} d\nu = \int \frac{\tilde{S}_{2t}(1_{A^c})}{P_\nu(\tau > t)^2} d\nu = \frac{P_\nu(\tau > 2t)}{P_\nu(\tau > t)^2} = \frac{R(2t)}{R(t)^2} \leq \frac{R}{(R(t))^2}. \tag{4.3} \]

Conversely, Let $\mu$ be a limit point of $\{1/t \int_{0}^{t} T_s(\nu) ds\}$ along the subsequence $\{t_n\}$ in weak-$L^2(d\nu)$. By Theorem 1 of [4], $\mu$ is a quasi-stationary measure with $P_\mu(\tau > t) = \exp(-\lambda t)$. Thus, (i) follows from
\[ \lim_{t \to \infty} R(t) = \lim_{n \to +\infty} \frac{1}{t_n} \int_{0}^{t_n} P_\nu(\tau > s) ds = \lim_{n \to +\infty} \int_{0}^{t_n} f_s \frac{d\mu}{d\nu_\rho} d\nu_\rho = \int \left( \frac{d\mu}{d\nu_\rho} \right)^2 d\nu_\rho < \infty. \tag{4.4} \]
Now, if either (i) or (ii) holds, by remark 3 of [4], we have that the Yaglom limit exists. Now, to show that $\int (f_t - f)^2 d\nu$ converges to 0, we only need to show that $\int f_t^2 d\nu$ converges to $\int f^2 d\nu$. It is easy to see from (4.3) and (4.4), that $\lim \int f_t^2 d\nu = \lim R(t) = \int (d\mu/d\nu)^2 d\nu$, and the proof of Lemma 2.3 is concluded.

### 5 Proof of Theorem 2.7 (i): Uniqueness

#### 5.1 Positivity of $f$

We first show that $\nu_\rho$-a.s., $f > 0$ on $\{\eta_0 = 0\}$. We introduce a symmetric simple exclusion process on $\mathbb{Z}^d \setminus \{0\}$: there is no site 0, and its adjacent bonds are suppressed. Let $\nu_\rho^*$ be the product Bernoulli measure on $\mathbb{Z}^d \setminus \{0\}$ of density $\rho$. Let $\{S_t^*, t \geq 0\}$ be the Markov semi-group of this process. It is known that the process $\{S_t^*, t \geq 0\}$, with initial measure $\nu_\rho^*$, is reversible and ergodic: indeed, by Theorem 1.44 on page 377 of [10], $\nu_\rho^*$ is an extremal invariant measure and by Theorem B.52, on page 23 of [11], all extremal invariant measures are ergodic. In other words, if for any $t > 0$, $S_t^* g = g$, $\nu_\rho^*$-a.s., then $g$ is constant $\nu_\rho^*$-a.s.

Let $\mathcal{B} := \{\eta : \eta_0 = 0, f(\eta) = 0\}$, and note that $\nu_\rho$-a.s.
\[ \tilde{S}_t 1_\mathcal{B} = \exp(-\lambda t) f 1_\mathcal{B} = 0. \]

Now, because $f \geq 0$, we have that for any $\varepsilon > 0$, $\varepsilon 1_{\{f > \varepsilon\}} \leq f$. Thus, for $\eta \in \mathcal{B}$, $\nu_\rho$-a.s.
\[ \forall \varepsilon > 0, \quad P^n(\{f(\eta_t) > \varepsilon\}, \tau > t) = 0 \implies P^n(\{f(\eta_t) > 0\}, \tau > t) = 0. \]
Now, if the bonds linking 0 to its neighbors are not marked, up to time \( t \), then \( \bar{S}_t \) acts like \( S_t^* \). So, if \( \tau_0 \) is the first time a Poisson mark appears in one of these bonds, for \( \eta \in \mathcal{B} \), \( \nu_{\rho} \)-a.s.

\[
P^n(f(\eta_0) > 0, \tau_0 > t) = 0,
\]

because \( \tau_0 \leq \tau \). Now, \( \tau_0 \) is independent from the Poisson processes on bonds of \( \mathbb{Z}^d \setminus \{0\} \), so

\[
P^n(f(\eta_0) > 0, \tau_0 > t) = S_t^*1_{\{f(\cdot) > 0\}} P(\tau_0 > t) = 0.
\]

Now, for any \( t > 0 \), \( P(\tau_0 > t) > 0 \). Thus, for \( \eta \in \mathcal{B} \), \( \nu_{\rho}^* \)-a.s.

\[
S_t^*1_{\{f(\cdot) > 0\}}(\eta) = 0.
\]

In other words, for any \( t > 0 \), we have \( \nu_{\rho}^* \)-a.s.

\[
S_t^*1_{\mathcal{B}} \geq 1_{\mathcal{B}}.
\]

Now, \( \nu_{\rho}^* \) is reversible for \( S_t^* \), so both expressions have the same mean, and we conclude that \( \nu_{\rho}^* \)-a.s., for any \( t > 0 \), \( S_t^*1_{\mathcal{B}} = 1_{\mathcal{B}} \). By the ergodicity of \( \nu_{\rho}^* \), we conclude that \( 1_{\mathcal{B}} \) is \( \nu_{\rho}^* \) constant, so that necessarily \( \nu_{\rho}(\mathcal{B}) = 0 \).

5.2 One eigenvalue with a positive eigenvector.

Suppose that \( f, f' \in \mathcal{H}_A \) are the densities of two quasi-stationary measures. There are two real numbers \( \lambda(\rho) \) and \( \lambda' \) such that \( f, f' \) satisfy in an \( L^2(\nu_{\rho}) \) sense

\[
\bar{S}_t f = e^{-\lambda(\rho)t} f, \quad \text{and} \quad \bar{S}_t f' = e^{-\lambda' t} f'. \tag{5.1}
\]

First, we show that \( \lambda(\rho) = \lambda' \). We assume that \( d\mu_{\rho} = f d\nu_{\rho} \) corresponds to the Yaglom limit. Thus,

\[
\lim_{t \to \infty} \int f' f d\nu_{\rho} = \int f' f d\nu_{\rho}, \quad \text{and} \quad \lim_{t \to \infty} \int f f d\nu_{\rho} = \int f^2 d\nu_{\rho}. \tag{5.2}
\]

However, as \( f > 0 \) on \( \{\eta_0 = 0\} \), \( \nu_{\rho} \)-a.s.,

\[
\frac{e^{-\lambda t} \int f' d\nu_{\rho}}{P_{\nu_{\rho}}(\tau > t)} = \frac{1_{\mathcal{A}^c} \bar{S}_t f' d\nu_{\rho}}{P_{\nu_{\rho}}(\tau > t)} = \int f' f d\nu_{\rho} \longrightarrow \int f' f d\nu_{\rho} > 0. \tag{5.3}
\]

Similarly,

\[
\int f f d\nu_{\rho} = \frac{e^{-\lambda(\rho)t} \int f d\nu_{\rho}}{P_{\nu_{\rho}}(\tau > t)} \longrightarrow \int f^2 d\nu_{\rho}. \tag{5.4}
\]

Thus, \( \lambda(\rho) = \lambda' \).
5.3 Dual expansion.

We expand $f$ on the countable basis of $L^2(\nu_\rho)$, say \( \{ H_A, \ A \in \mathcal{P} \} \), where $\mathcal{P}$ is the collection of finite subsets of $\mathbb{Z}^d$ and

\[
H_\emptyset = 1, \quad \text{and} \quad H_A(\eta) = \prod_{i \in A} \frac{(\eta_i - \rho)}{\sqrt{\rho(1 - \rho)}}.
\] (5.5)

Thus, there are real numbers \( \{ C_A, \ A \in \mathcal{P} \} \) with

\[
f = \sum_{A \in \mathcal{P}} C_A H_A, \quad \text{and} \quad \int f^2 d\nu_\rho = \sum_{A \in \mathcal{P}} C_A^2.
\] (5.6)

The constraint that $f \in H_A$, i.e. $\eta_0 f(\eta) = 0$, is equivalent to

\[
\forall A \not\ni 0, \quad \int H_A \eta_0 f d\nu_\rho = 0.
\] (5.7)

Thus,

\[
\sqrt{\rho(1 - \rho)} \int H_{A \cup \{0\}} f d\nu_\rho + \rho \int H_A f d\nu_\rho = 0.
\] (5.8)

So, for $A \not\ni 0$,

\[
\sqrt{\rho(1 - \rho)} C_{A \cup \{0\}} + \rho C_A = 0.
\] (5.9)

We define for all $A \in \mathcal{P}^*$

\[
\psi(A) = \left( -\sqrt{\frac{1 - \rho}{\rho}} \right)^{|A|} C_A.
\] (5.10)

Now, condition (5.9) reads $\psi(A \cup \{0\}) = \psi(A)$ for $A \not\ni 0$. Now, we express $(-L f, f)$ in terms of the $\{C_A\}$.

\[
(-L f, f) = \sum_{A \in \mathcal{P}} \sum_{B \sim A} (C_B - C_A)^2,
\] (5.11)

where $B \sim A$ if there is $i \in A \setminus B$ and $j \in B \setminus A$ with $A \Delta B = \{i, j\}$. We replace the $C_A$’s by the $\psi(A)$’s and distinguish $0$ to eliminate (5.9)

\[
(-L f, f) = \sum_{A \not\ni 0} \left( \sum_{B \not\ni 0, B \sim A} \gamma^{|A|}(\psi(B) - \psi(A))^2 + \sum_{B \ni 0, B \sim A} \gamma^{|A|}(\psi(B \setminus \{0\}) - \psi(A))^2 \right)
\]

\[
+ \sum_{A \not\ni 0} \left( \sum_{B \ni 0, B \sim A} \gamma^{|A|}(\psi(B \setminus \{0\}) - \psi(A \setminus \{0\}))^2 + \sum_{B \not\ni 0, B \sim A} \gamma^{|A|}(\psi(B) - \psi(A \setminus \{0\}))^2 \right)
\]

\[
= \sum_{A \not\ni 0} \left[ \sum_{B \in \mathcal{N}_A} \gamma^{|A|}(1 + \gamma)(\psi(B) - \psi(A))^2 + \sum_{B \in \mathcal{N}^+_A} \gamma^{|A|}(\psi(B) - \psi(A))^2 \right.
\]

\[
+ \sum_{B \in \mathcal{N}^-_A} \gamma^{|A|+1}(\psi(B) - \psi(A))^2 \right],
\] (5.12)

where $\gamma = (1 - \rho)/\rho$, $B \in \mathcal{N}_A$ means $B \sim A$ and $B \not\ni 0$, $B \in \mathcal{N}_A^+$ means $B \sim A \cup \{0\}$ and $B \not\ni 0$, and $B \in \mathcal{N}_A^-$ means $B \cup \{0\} \sim A$ and $B \not\ni 0$. With this rewriting, $(-\bar{L} f, f)$ can be
thought of as the Dirichlet form, $\mathcal{E}(\psi, \psi)$, of a dynamics with finitely many particles, with creation and annihilation at site 0, with respect to a measure $m(A) = \gamma^{|A|}$. The advantages of this rewriting are threefold: (i) the constraint (5.9) has vanished, (ii) the new dynamics is clearly irreducible and (iii) in studying the minimizers of $\mathcal{E}(\psi, \psi)$, we can assume the $\{\psi(A)\}$ to be nonnegatives. Indeed, note that $\mathcal{E}(\psi, \psi) \geq \mathcal{E}(|\psi|, |\psi|)$ and equality holds only if $\psi(A) \geq 0$ for each $A \in \mathcal{P}^*$. Also, we rewrite the $L^2(\mu)$ norm of $f$ in terms of the $\{\psi(A), A \in \mathcal{P}^*\}$

$$|f|^2 = \sum_{A \neq 0} C_A^2 + C_{A \cup \{0\}}^2 = (1 + \gamma) \sum_{A \neq 0} \psi(A)^2 \gamma^{|A|} = (1 + \gamma) ||\psi||_m^2. \quad (5.13)$$

Now, $Lf + \lambda f = 0$ implies that for $A \in \mathcal{P}^*$

$$(1 + \gamma) \sum_{B \in N_A} (\psi(B) - \psi(A)) + \gamma \sum_{B \in N_A^{-}} (\psi(B) - \psi(A)) + \sum_{B \in N_A^{+}} (\psi(B) - \psi(A)) = -\lambda \psi(A). \quad (5.14)$$

Thus, $\psi(A) > 0$ for all $A \in \mathcal{P}^*$. Now, let $\phi = \psi^2$ and note that for any $A$ and $B \in \mathcal{P}^*$, the functional $\phi \mapsto (\sqrt{\phi(B)} - \sqrt{\phi(A)})^2$ is convex. Assume that $\psi$ and $\psi'$ are two positive normalized minimizers, and let $\phi$ and $\phi'$ be their respective squares. Then, for any $\lambda \in [0, 1]$

$$\psi_\lambda := \sqrt{\lambda \phi + (1 - \lambda) \phi'} \text{ has } ||\psi_\lambda||_m = 1 \quad \text{ and } \quad \mathcal{E}(\psi_\lambda, \psi_\lambda) \leq \lambda \mathcal{E}(\psi, \psi) + (1 - \lambda) \mathcal{E}(\psi', \psi').$$

Thus, the convex inequality is an equality, so that for any $A \in \mathcal{P}^*$ and any $B \in N_A \cup N_A^{-} \cup N_A^{+}$

$$(\psi_\lambda(B) - \psi_\lambda(A))^2 = \lambda (\psi(B) - \psi(A))^2 + (1 - \lambda) (\psi'(B) - \psi'(A))^2,$$

which implies, after expanding, that $\phi(A) \phi'(B) = \phi(B) \phi'(A)$. Now, as $\phi(A) > 0$ and the dynamics is irreducible, we conclude that $\phi \equiv \phi'$ and so are the positive square-roots $\psi \equiv \psi'$.

6 Proof of Theorem 2.7 (ii) and (iii)

6.1 Proof of Theorem 2.7 (ii): Density at infinity

The facts that for any $t > 0$, $\nu_{\alpha(i)} \prec T_i(\nu_\rho) \prec \nu_\rho$ with $\alpha(i) \to \rho$ when $||i|| \to \infty$ implies that for any $A \in \mathcal{P}$

$$\int \prod_{j \in A} \eta_{i+j} d\mu_\rho(\eta) \quad \lim_{||i|| \to \infty} \rho^{|A|},$$

for $\prod_{j \in A} \eta_{i+j}$ is an increasing function. Now any local function $\varphi$ can be written as a linear combination of local increasing functions, and the property follows by linearity.

6.2 Proof of Theorem 2.7 (iii): Basin of Attraction

We show that for any measure $\nu$, any subsequence of the Cesàro limit of $\{T_i(\nu)\}$ contains a further subsequence converging to a quasi-stationary measure, say $\mu$. When the density of $\nu$ with respect to $\nu_\rho$, say $\phi$, is continuous, we show that $\mu = \mu_\rho$. As in the proof of existence of
a quasi-stationary measure (see [4] Lemma 1), we establish first the existence, for any $s > 0$, of the following limit
\[
\lim_{t \to \infty} \frac{P_\nu(\tau > t + s)}{P_\nu(\tau > t)} = \exp(-\lambda(\rho)s).
\]
(6.1)

Indeed, recall that
\[
P_\nu(\tau > t) = \int \tilde{S}_t(1_{A^c})1_{A^c}\phi d\nu_\rho = \int \tilde{S}_t(1_{A^c}\phi) d\nu_\rho,
\]
so that by the existence of the Yaglom limit
\[
\lim_{t \to \infty} P_\nu(\tau > t) = \int \phi d\mu_\rho > 0.
\]
(6.2)

Thus,
\[
\lim_{t \to \infty} \frac{P_\nu(\tau > t)}{P_\nu(\tau > t)} = \lim_{t \to \infty} \frac{P_\nu(\tau > t + s)}{P_\nu(\tau > t)} = \exp(-\lambda(\rho)s).
\]
(6.3)

By the weak* compactness, for any sequence $\{t_n\}$, there is a further subsequence (still named $\{t_n\}$ for convenience), and a probability measure $\mu$, such that for any continuous function $\varphi$
\[
\frac{1}{t_n} \int_0^{t_n} (T_t(\nu), \varphi) dt \to \int \varphi d\mu.
\]
(6.5)

The same argument as in the proof of Theorem 1 of [4] implies that $\mu$ is quasi-stationary. Now, we establish apriori estimates
\[
\int \left( \frac{dT_t(\nu)}{d\nu_\rho} \right)^2 d\nu_\rho = \int \left( \frac{E^\eta[\phi(\eta_t)1_{\{\tau > t\}}]}{P_\nu(\tau > t)} \right)^2 d\nu_\rho \\
\leq \left| \phi \right|^2 \int \left( \frac{P_\nu(\tau > t)}{P_\nu(\tau > t)} \right)^2 d\nu_\rho = \left| \phi \right|^2 \int f^2 d\nu_\rho \left( \frac{P_\nu(\tau > t)}{P_\nu(\tau > t)} \right)^2.
\]
(6.6)

This quantity is bounded by Corollary 2.5 and (5.3). By standard arguments, this implies that $\mu \in L^2(\nu_\rho)$ which by the uniqueness result establish that $\mu = \mu_\rho$, so that the Cesàro limit exists and is $\mu_\rho$.

Acknowledgements. A.A. thanks for their warmth, the faculty and staff of the mathematics department of São Paulo University, where part of this research was conducted. Also, we would like to thank Fabienne Castell and Enrique Andjel for suggestions and Paolo Dai Pra for pointing out an error in the first version.
