This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
A Study of Dye Anchoring Points in Half-squarylium Dyes for Dye-
Sensitized Solar Cells

Arthur Connell, Peter J. Holliman, Matthew L. Davies, Christopher D. Gwenin, Sophie Weiss, Mateusz B. Pitak, Peter N. Horton, Simon J. Coles and Graeme Cooke

Received (in XXX, XXX) Xth XXXXXXXXX 20XX, Accepted Xth XXXXXXXXX 20XX
DOI: 10.1039/b000000x

This paper reports the synthesis of a series of new half-squaraine dyes (Hf-SQ) based around a common chromophoric unit consisting of linked indoline and squaric acid moieties. Carboxylate groups have been incorporated onto this core structure at four different points to study the influence of the anchoring group position on dye-sensitized solar cell (DSC) device performance. Dyes have been linked to TiO$_2$ directly through the squaric acid moiety, through a modified squaric acid unit where a vinyl dicyano group has replaced one carbonyl, via an alkyl carboxylate attached to the indole N or through a carboxylate attached to the 4 position of a benzyl indole. Contact angle measurements have been studied to investigate the hydrophobic/hydrophilic properties of the dyes and the results have been compared to N719 and Z907.

Full characterization data of all the dyes and synthetic intermediates are reported including single-crystal X-ray structural analysis for dye precursors; the indole (2a) and the half-squarylium esters (3a) and (6b), as well as the dyes (4c), (8) and (12). Dye colours range from yellow to red/brown in solution ($\lambda$ range from 430 to 476 nm) with $\varepsilon$ ranging from 38,000 to 133,100 M$^{-1}$ cm$^{-1}$. The performance of the dyes in DSCs shows the highest efficiency yet reported for a Hf-SQ dye (η = 5.0%) for 1 cm$^2$ devices with a spectral response ranging from 400 to 700 nm depending on the dye substituents. Co-sensitization of half-squarylium dye (7b) with squaraine dye (SQ2) resulted in a broader spectral response and an improved device efficiency (η = 6.1%). Density functional theory (DFT) calculations and cyclic voltammetry have been used to study the influence of linker position on dye HOMO-LUMO levels and the data has been correlated with I-V and EQE data.

O’Regan and Grätzel’s breakthrough in DSC devices used Ru bipyridyl dye N3 to sensitize nanoparticulate TiO$_2$. Since 1991, Ru-bipy dyes have remained a widely used family of DSC dyes. However, these dyes are expensive which is partly due to raw material costs but also due to lengthy purification procedures which hinder scaling and they have relatively low molar extinction coefficients ($\varepsilon$) and generally poor spectral response above 600 nm leading to DSC efficiencies of 11.1% for N719 and 11.4% for C101. This has led to the development of “Ru-free” organic DSC dyes (e.g. triphenylamines, coumarins and indolines) which absorb in the same region as Ru-bipy dyes (450-600 nm) where AM1.5 solar intensity is highest. Generally, these organic dyes are simpler to purify than Ru-bipy complexes and have significantly higher $\varepsilon$. This allows thinner photo-electrodes to be used which can reduce recombination losses and improve device voltages. High $\varepsilon$ is also advantageous when co-sensitizing the TiO$_2$ electrode to broaden spectral response because if fewer dye sorption sites utilized for the dye harvesting light at 400-650 nm, this leaves more space for near infrared (NIR) dyes which absorb at $\lambda > 650$ nm.

Extending DSC spectral response remains key to increasing device efficiency. This has led to the development of panchromatic dyes (e.g. “Black dye”, squaraine). However, the synthetic and purification procedures associated with such dyes make them expensive and ensuring optimized spectral response across 400-900 nm in a single dye has proved very difficult. Co-sensitizing DSC photo-anodes with combinations of two or more dyes is another approach to increasing light harvesting which has led to the first reports of ultra-fast co-sensitization and η > 12% for a combination of porphyrin and triphenylamine dyes.

Co-sensitization requires dyes which can harvest longer wavelength photons. In this context, squaraines have been studied as DSC dyes because of their high $\varepsilon$ and $\lambda_{\text{max}} \geq 650$ nm where Ru-bipy dyes are less effective sensitizers. Half-squarylium (Hf-SQ) dyes are produced as an intermediate during the synthesis of unsymmetrical squaraine dyes. Hf-SQ dyes are known to be fluorescent and have been tested in ZnO giving η = 0.27%.

Table 3 Contact angles for dyes sorbed on TiO₂ photo-electrodes

| Surface | Contact angle/° |
|---------|-----------------|
| N719    | 45.8 ± 3.0      |
| Z907    | 110.1 ± 5.0     |
| (7b)    | 42.3 ± 3.0      |
| (8)     | 25.5 ± 3.0      |
| (10)    | 38.7 ± 3.0      |
| (12)    | 106.2 ± 4.0     |

dicyano-derivatized squaraine unit and on the benzyl of the indole, respectively have been confirmed by, single crystal X-ray analysis (Fig. 1) and (Fig. 6 ESI). Whilst some structurally-related Hf-SQ dyes and their precursors have been reported previously20,30, (5), (6b), (7b) and (8) are variants (see ESI) with a dodecyl chain attached to the nitrogen of the indole. The spectroscopic data for these new compounds are in line with the previously reported data (see ESI for references). Dye (10) is significantly different to previously reported Hf-SQ dyes due to the linker being attached to the nitrogen of the indole. However, the ¹H and ¹³C NMR of (10) show resonances in the expected regions for the various functional groups in the molecule and high resolution mass spectrometry has identified the expected mass for this compound. In addition, the expected functional groups, including the carboxylate moiety, have been identified using infrared spectroscopy and (10) has a λ_max of 440 nm and an extinction coefficient of 116,000 M⁻¹ cm⁻¹ in ethanol measured using UV-visible spectroscopy.

The new dyes in this paper have been designed with bulky side groups to try to minimize inter-molecular interactions which can give rise to dye aggregation and increased recombination processes between adsorbed dye molecules on the TiO₂ surface. This is an established approach to DSC dye design, which has been described previously2,3. However, this can make it more difficult to grow single crystals for X-ray analysis which hinders structural studies of DSC dyes. Using careful purification and slow evaporation, it was possible to grow suitable crystals of several HF-SQ dyes and precursors reported including; (4c), the esterified precursor of (7b) i.e. (6b), (8) and (12). Analysis of the crystal structure obtained from (4c) i.e. the molecule containing the longest and potentially most hydrophobic alkyl unit (Fig. 4, ESI and Table 1) shows a complex structure where the negatively charged squaric acid moiety is balanced by sodium ions but with several molecules H-bonded together through the carbonyl and C-OH of this acylom moiety (ESI, Fig 5 and Table 4). The hydrophobic hexadecyl alkyl chain is then arranged pointing away from the hydrophilic, electrostatically charged squaric acid.

the case for (12) and therefore the position of the linker group and alkyl chains result in a reorientation of the alkyl chain to repel hydrophilic species. Equilibrium dye loading measurements show that 81.7 µg cm\(^{-2}\) of (7b) sorbs to titania whilst (10) and (12) show comparable and much lower dye loadings at 33.9 and 34.0 µg cm\(^{-2}\). It was not possible to measure the dye loading of (8) because this dye bleached rapidly and completely on exposure to alkali. Dye loading correlates with \(J_{sc}\) for (7b), (10) and (12) with the highest dye loading and \(J_{sc}\) for (7b) whilst lower dye loadings and \(J_{sc}\) are observed for (10) and (12). In addition, the broader spectral response of (10) relative to (12) explains the increased \(J_{sc}\) of (10) compared to (12). The dye loading data further suggest that dye orientation is important and appears to be more influential than dye loading when influencing contact angles (assuming dye uptake is complete). Interestingly, very low contact angles were observed for all dyes when measurements were made using the electrolyte solvent methoxypropionitrile instead of water suggesting complete wetting of the surface should occur in DSC devices. This should ensure the redox couple (I\(_3^–\)/I\(_2^-\)) is able to interact with the dye-oxide surface avoiding any dye regeneration limitations on device performance.

The optical properties of the dyes (7b), (8), (10) and (12) have been studied both in solution and adsorbed to translucent TiO\(_2\) films (Fig. 3). (12) has a \(\lambda_{max}\) of 428 nm (133,100 M\(^{-1}\)cm\(^{-1}\)) in solution which red shifts to 444 nm when adsorbed to TiO\(_2\). Bathochromic shifts are observed for (7b) \(\lambda_{max}\) at 442 nm, 38,000 M\(^{-1}\)cm\(^{-1}\) and (10) \(\lambda_{max}\) at 440 nm, 116,000 M\(^{-1}\)cm\(^{-1}\) in solution which are attributed to the increased conjugation from the napthyl indole by comparison to the benzyl indole in (12). (10) also exhibits narrower absorption peaks than (7b) and the solution appears bright orange by comparison to the more diffuse yellow hue of (7b) and (12). Furthermore, a decrease in the extinction coefficient is observed for (7b) compared to (6b) which is similar to observations reported in the literature for other de-esterified HF-SQ molecules\(^{36, 39}\). A relatively large bathochromic shift and significantly broadened absorption peaks are observed for (7b) and (10) when adsorbed to TiO\(_2\) (Fig. 3). To help understand these effects, the HOMO and LUMO maps for molecules (7a), (8), (10) and (12) have been calculated (Fig. 4). All of the dyes show that both the HOMO and LUMO are delocalized throughout the \(\pi\)-framework although there is significantly greater electron density for the LUMO around the squaric acid unit and at the nitrogen of the indole group. This should result in greater electronic interaction between the anchoring unit and TiO\(_2\) surface which contributes to the broader absorption spectra for (7a), (8) and (10) which link via these groups by comparison to (12) which links via a benzyl carboxylate. Interestingly, the HF-SQ/TiO\(_2\) interface has also been investigated using DFT calculations by Cicero et. al\(^{38}\) which also shows that the HOMO is delocalized through the \(\pi\)-framework of the whole structure while the LUMO contains a notable electron density contribution arising from the squaric acid group\(^{38}\). These workers reported that the HOMO-LUMO transition should therefore move electron density to the anchoring group resulting in directional electron transfer to the TiO\(_2\) surface\(^{38}\). A similar phenomenon should also occur in the dyes reported here. Finally, incorporating the vinyl dicyano entity into the HF-SQ central unit in (8) results in the largest peak broadening and bathochromic shift both in solution \(\lambda_{max}\) at 476 nm, 57,700 M\(^{-1}\)cm\(^{-1}\) and when adsorbed to TiO\(_2\) films. Whilst this influence of the electron donating vinyl dicyano group is similar to that reported for squaraines\(^{23, 32}\), to the best of our knowledge, this effect has not yet been reported for half-squaraines.

Table 4 IV data for DSC devices prepared using various half-squaraine dyes. Errors on device efficiencies are ± 0.2%.

| Dye | \(n/\%\) | FF | \(V_{oc}/\text{V}\) | \(J_{sc}/\text{mA cm}^{-2}\) |

DSC device testing

Table 4 shows I-V data for selected Hf-SQ devices. Initially, DSC devices were prepared with and without 5 mM the additive chenodeoxycholic acid (CDCA). However, the power conversion efficiencies of devices without CDCA were always at least 25% lower than those with CDCA; see e.g. (10) or (12) due to slight improvements in \(J_{sc}\), \(V_{oc}\) and FF. This is in line with published reports that CDCA suppresses aggregation\(^{38, 32}\) and affects the position of the conduction band resulting in improved electron injection\(^{32}\).

Table 4 shows device data for TiO\(_2\) devices sensitized with HF-SQs containing either benzyl or napthyl indoles with alkyl chains of varying length (ethyl to octadecyl). Comparing the benzyl indole dyes (4a-e) shows very similar device performance data for all three dyes with \(\eta\) ranging from 3.3-3.8%. The variance was mainly due to differences in \(J_{sc}\) which ranges from 7.9-9.2 mA cm\(^{-2}\) with very similar \(V_{oc}\) values observed for all three dyes (ca. 0.65 V). The slightly lower \(J_{sc}\) value was observed for the indole with the longest alkyl chain (hexadecyl) may reflect slightly poorer electron injection or dye regeneration from the electrolyte but this is only has a relatively small effect on \(\eta\). However, after synthesis, this dye was also the most difficult to purify from the iodohexadecane precursor by comparison to the shorter chain iodoalkane dyes and precursors which may also have had a slight negative effect on \(J_{sc}\) for (4c).
to compare dye oxidation and reduction processes with spectral
and DSC device data along with theoretical DFT calculations to
try to further examine any structure-activity relationships arising
from changes to the dye linker position. The CV data for (7b)
show three anodic waves (Fig. 5) similar to that reported in the
literature.

Table 5 Band-gap ($E_h$) calculated from the absorption onset, cyclic
voltammetry and DFT calculations for dyes (7b), (8), (10) and (12).

| Dye | $\lambda$ onset/ nm | $E_h$ calc. from $\lambda$ onset/ eV | $E_h$ calc. from CV/ eV |
|-----|--------------------|----------------------------------|-------------------------|
| (7b) | 556                | 2.20                             | 2.23                    |
| (8)  | 526                | 2.35                             | 2.40                    |
| (10) | 476                | 2.60                             | 2.60                    |
| (12) | 472                | 2.62                             | 2.5                    |

Shifts in the anodic and cathodic waves were observed for (8) and
(10) which were expected from the changes in the electronic
spectra of these dyes (Fig. 3). The CV data have been used to
calculate the HOMO-LUMO potentials and band gaps versus the
NHE and the band gap energies obtained correlate well with the
onset of the absorption measured from the solution UV-Visible
spectroscopy. For example, the bandgap calculated from the
absorption onset obtained for (7b), (8) and (10) is 2.20, 2.35 and
2.60 (eV) respectively which correlates with the bandgap
energies of 2.23, 2.4 and 2.6 (eV) calculated from the CV data.

By comparison, the anodic and cathodic waves measured for (12)
are not as clear as for the other dyes (see ESI). However, a
sensible estimation of the HOMO-LUMO energy gap i.e. 2.62
(eV) could still be made by using the bandgap of 2.6 (eV)
calculated from absorption onset obtained from solution UV-
visible spectroscopy. Furthermore, both the DFT and CV data
(Figs. 4 and 5) suggest that the LUMO levels of (7b), (8), (10)
and (12) should be at the correct energy for successful electron
injection from the dye into the TiO$_2$ conduction band and that the
energy of the HOMO levels should enable successful
regeneration of the dye using an I$_3$/I$_2$ redox couple in the
electrolyte.

To study the influence of linker position, the performance of
(7b), (8), (10) and (12) were evaluated in DSC devices with and
without CDCA (Table 4). Interestingly, it was not possible to
include CDCA with (8) as this caused desorption of the sensitizer
from the TiO$_2$ surface. However, where CDCA was present,
device efficiency was consistently improved due to increased $V_{oc}$
as has been widely reported in the literature for various dye
systems. Further desorption of (8) was also observed when an
electrolyte was introduced into the device which meant that the I-V
data for (8) was measured immediately after electrolyte
addition. The desorption problems of (8) meant that, despite
having the highest photocurrent of all dyes reported in this study
($J_{oc} > 11$ mA cm$^{-2}$), the overall efficiency was limited to $\eta = 2.8$
\% as a result of much lower $V_{oc}$ and FF which must reflect the
significant changes to the photo-electrode surface during
desorption. These problems are ascribed to the addition of the
vinyl dicyano group to one carbonyl of the squaric acid unit

Studying the effects of alkyl chain length on the naphthyl
indoles of dyes (7a) and (7b) shows two main differences. Firstly,
a significant uplift in $\eta$ is observed for the naphthyl indoles (4.0-
5.0\%) compared to their benzyl indoles which mainly results
from increased $J_{sc}$ (10.2-10.9 mA cm$^{-2}$). This $J_{sc}$ increase is
attributed to a slight broadening of the absorption spectra due to
the extended conjugation of the naphthyl indole. This is in line
with literature data for squaraines which report improved $\eta$ for
the naphthyl indole squaraine, SQ2 versus the benzyl indole,
SQ1. Interestingly, for the naphthyl indoles, increasing the
length of the alkyl chain attached to the indole N from an ethyl
group in (7a) to a dodecyl chain in (7b) increases $V_{oc}$ from 0.61
to 0.71 V respectively. This is the highest $V_{oc}$ observed for the
Hf-SQ dyes reported here which, along with an improved FF,
gives the highest single dye efficiency ($\eta = 5.0\%$). In addition,
the $V_{oc}$ of 0.61 V observed for (7a) is close to the literature value
of 0.64 V reported elsewhere for this dye. We believe this to be
the highest efficiency Hf-SQ reported to date. The improved $V_{oc}$
and FF may be due to decreased dye aggregation on the TiO$_2$
photo-electrode which could be caused by the longer alkyl chain
in (7b) sterically reducing inter-dye interactions. Due to the
improved device performance of (7b) by comparison to (4a-c)
or (7a), the dye (7b) was taken forward for further study using co-
sensitization studies and for comparison with dyes (8), (10) and
(12).

Cyclic voltammetry (CV) measurements of (7b), (8), (10) and
(12) in solution (10 mM in degassed THF) have been carried out

Fig. 6 EQE of (a) (7b) dotted line, (8) long dashes, (10) short dashes and
(12) solid line and (b) (7b) dotted line and (7b) + SQ2.
which in (8) must act as the linker group to the TiO₂ surface. This new group, rich in π-related electron density, presumably increases steric hindrance at the dye sorption site. Whilst this does not prevent the formation of an ester link between the dye and TiO₂ surface, it does appear to weaken this interaction to the extent that dye desorption occurs more easily. Indeed, desorption in the presence of the electrolyte suggests a dye binding energy of the same order as iodide which means the dye and electrolyte anions are competing for surface sorption sites. The instability of (8) is further evidenced by the fact that it bleaches on exposure to alkali (see earlier dye loading discussion).

Fig. 6 shows that the spectral responses of (7b), (8), (10) and (12) are all slightly red shifted by comparison to the corresponding absorption spectra of TiO₂ dyed films (Fig. 3). The narrowest spectral response and absorption data are observed for (12) which correlate with the lowest Jₘ and η of these four dyes. Interestingly, the carboxylate linker in (12) is placed on the benzene ring and so is expected to lie furthest from greatest electron density of the LUMO on the squaraine moiety. In addition, (12) has the least conjugation of the 4 dyes tested here which limits the extent of spectral response. This is despite this dye having the highest ε of the four dyes tested here (133,100 M⁻¹ cm⁻¹) which reflects the importance of electron injection over simply light harvesting. By comparison, the broadest spectral response (out to ca. 650 nm) and absorption data are observed for (8) which reflect the much greater conjugation in this molecule arising from the addition of the napthyl indole and vinyl dicyano moieties. The broader light harvesting gives rise to the highest Jₘ despite this dye having a moderate ε of (57,700 M⁻¹ cm⁻¹). Dye (10) shows a slightly broader spectral response compared to (12) at ca. 400 nm along with a shoulder at ca. 575 nm which is reflected in the higher Jₘ; 8.12 versus 5.44 mA cm⁻². These two dyes have almost identically high ε relative to (7b) and (8) and although Jₘ is improved for (10), it is lower than for (7b) which presumably is related to the fact the linker group is attached to the N of the indole. This means the linker is closer to the LUMO electron density on the squaraine ester but that electron injection must occur through the N of the indole. In squaraine dyes, it has been reported that charge generation occurs around the squaraine moiety during photo-excitation but that electron transfer through the indole nitrogen such as that which occurs in the dye B1 is less efficient than through a pathway composed entirely of carbon and hydrogen atoms as occurs in SQ1. The highest spectral response is observed for (7b) which approaches 75% between ca. 410 and 550 nm. This is despite (7b) having the lowest ε of these 4 dyes (38,000 M⁻¹ cm⁻¹). This is ascribed to the linker group being the squaric acid moiety where DFT calculations (Fig. 4) show that the greatest LUMO electron density is found. Hence, electron injection should be enhanced by the proximity of the LUMO to the TiO₂ surface resulting in increased Jₘ (over 10 mA cm⁻²) despite significantly narrower spectral response than (8). To the best of our knowledge (7b) gives rise to the highest efficiency reported for a Hf-SQ DSC dye to date.

In an attempt to improve device and broaden the spectral response further towards the NIR, (7b) was co-sensitized with squaraine dye SQ2 using a fast pump dyeing method reported elsewhere. The spectral response for a co-dyed (7b)/SQ2 device shows significantly greater light harvesting out to ca. 700 nm leading to a significant increase in Jₘ to 14.61 mA cm⁻² and η = 6.1% (Table 4). By comparison, an efficiency of 6.4% was obtained for a device sensitized using N719. In addition, the performance of this co-dyed device is very similar to many panchromatic SQ dyes reported but has the advantage that a complicated synthesis is not required to incorporate the molecular entities required for higher energy photon harvesting across the solar spectrum. This could encourage research efforts to be directed towards incorporating molecular entities into dye systems that broaden the spectral response further into the near infrared as another approach alongside the development of panchromatic responses from individual dye systems.

Experimental

Instrumentation and chemicals

All chemicals were purchased from Aldrich and used as supplied unless otherwise stated. Anhydrous solvents were used as purchased except THF which was dried with Na wire. NMR spectra were recorded on a Bruker AC500 instrument operating at 500 MHz for 1H and 125 MHz for 13C. Chemical shifts (δ) are given in ppm relative to tetramethylsilane (for 1H and 13C). J values are given in Hz and refer to J_HH unless otherwise indicated. Mass spectra were recorded using electron impact, chemical ionisation (NH₃), fast atom bombardment, electrospray, matrix-assisted laser desorption ionisation and laser desorption ionisation at the EPSRC National Mass Spectrometry Service at the University of Swansea. Infrared spectra were recorded on a Perkin-Elmer 1600 series FTIR spectrometer. Elemental analysis was performed on a Carlo Erba EA1108 elemental analyser. Dye loadings were measured by desorption from 1 cm² TiO₂ electrodes using 40 mM Bu₄NOH in 1:1 v/v ethanol/water according the method described previously. The concentration of dye in solution was measured using UV/Visible spectroscopy and dye loadings were calculated (µg cm⁻²) using the appropriate ε (see ESI) and the Beer-Lambert Law.

Cyclic voltammetry was measured on dyes (5 mM) at room temperature in N₂-saturated anhydrous tetrahydrofuran (THF) using 0.1 M tetrabutylammonium hexafluorophosphate (Bu₄NPF₆) as the supporting electrolyte. Measurements were performed using an Autolab PGSTAT 30 computer-controlled electrochemical measurement system (Eco Chemie, Holland). with a sweep rate of 0.05 V s⁻¹ in a three-electrode cell with a glassy carbon (1 cm²) working electrode, a silver/ silver chloride (Ag/AgCl) reference electrode and a Pt sheet (1 cm²) counter electrode. All voltammetric potentials were re-calculated and are reported versus NHE.

X-ray crystallography

Single-crystal X-ray diffraction analyses of 3a, 4c_salt and 5a were performed at 120 K using a Bruker APEXII CCD diffractometer mounted at the window of a Bruker FR591 rotating anode (Mo Kα, λ = 0.71073Å ) and equipped with an Oxford Cryosystems Cryostream device. Data were processed using the COLLECT package.
The X-ray data for compounds 2a, 2b, 4b_salt, 6b, 6c, 9, 12(I) and 12(II) were collected at 100 K on Rigaku AFC12 goniometer equipped with an enhanced sensitivity (HG) Saturn 724+ detector mounted at the window of an FR-E+ Superbright MoKα rotating anode generator with HF Varimix optics. The X-ray data for compound 8_salt were collected with the use of synchrotron radiation at Diamond Light Source UK, beamline 119 (λ=0.6889Å) on a Crystal Logic diffractometer and Rigaku Saturn 724+ detector.

Unit cell parameters were refined against all data. For 3a, 4e_salt, 5a an empirical absorption correction was carried out using SADABS, whereas for 2a, 2b, 4b_salt, 6b, 6c, 9, 12(I) and 12(II) CrystalClear software was used. All structures were solved by direct methods and refined on F0 by full-matrix least-squares refinements using programs of the SHELX-97/SHELX-2013 software. All non-hydrogen atoms were refined with anisotropic displacement parameters. All hydrogen atoms were added at calculated positions and refined using a riding model with isotropic displacement parameters based on the equivalent isotropic displacement parameter (Ueq) of the parent atom.

The crystal structure of 4c_salt is non-merohedrally twinned (180° rotation around 001 reciprocal vector). EvalCCD was used to integrate the domains and the structure was refined using the HKL-5 instruction in Shelix. The refined percentage ratio of the twin domains was 25:75 (refined BASF = 0.25714). The crystal data for 8_salt is not of the highest quality, but is sufficient to prove structural connectivity.

The long aliphatic chains present in the crystal structures of 8_salt and 12(II) are disordered and modelled over two sites. For disordered components vibrational restraints (SIMU/DELU), similar displacement restraints (EADP) and distance/angle restraints DFIX/DANG used to maintain sensible geometries and atomic displacement ellipsoids. Some atoms required ISOR restraint to approximate isotropic behaviour. Crystal structure of 4b_salt exhibits positional disorder which has been modelled over two sites. Additionally, in 4b_salt highly diffused solvent electron density has been removed with PLATON/SQUEEZE routine.

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre; CCDC deposition numbers 977417-977428 contains the supplementary crystallographic data for this paper. This data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Theoretical Calculations
All calculations were performed using Spartan '08. Geometries were first optimized semi-empirically (AM1) and then reoptimized using DFT (B3LYP/6-31G*) level of theory. The optimized structures were shown to be local minima on their respective potential energy surfaces, as none of the vibrational frequencies.

Preparation of 1,1,2-Trimethyl-1-dodecyl-1H-benzo[e]indole (5b)
A mixture of 1,1,2-trimethyl-1H-benzo[e]indole (8 g, 38 mmol) and dodecyl iodide (25 g, 87 mmol) was heated under reflux overnight under nitrogen in anhydrous acetonitrile (80 ml). After cooling, the solvent was removed in vacuo and the product was re-crystallized from ethyl acetate to give a green solid. (Yield 17.5 g, 90%).

Device manufacture and testing

Photo-electrodes (0.5 x 2 cm = 1.0 cm\textsuperscript{2}) were prepared by doctor
blading two layers of TiO\textsubscript{2} colloid (DSL18NRT, Dyesol)
followed by one layer of scattering TiO\textsubscript{2} colloid (WER4-O,
Dyesol) onto fluorine tin oxide-coated glass (TEC15, 15 \text{ \Omega } \text{cm}^-2). Each TiO\textsubscript{2} layer was calcined at 723K for 30 min, then immersed
in TiCl\textsubscript{4}·THF in deionised water (50 mM) at 343 K for 30 min,
rinsed with de-ionised water, air-dried for 10 min and re-sintered
at 723 K for 30 min. Counter electrodes were prepared by drilling
two holes ca. 2 cm apart through TEC\textsuperscript{TM} glass (NSG),
washing with \text{PrOH} and drying in air before depositing Pt
colloid (Pt-I, Dyesol) and sintering at 400 °C for 30 min. The two
electrodes were sealed together using a Surlyn\textsuperscript{TM} (DuPont)
gasket at 120 °C. Contacts were applied onto both electrodes using
conductive silver paint (Agar).

Current-voltage characteristics were measured using an ABET
Solar Simulator with Xe arc lamp and a Keithley 2400 at 100
mW cm\textsuperscript{-2} or 1 Sun between 0 and 1 V. Spectral response
measurements were made on a QEX10 Quantum Efficiency
Measurement System in DC mode at resolution of 10 nm. Lamps
were calibrated to 1 Sun (100 mW cm\textsuperscript{-2}) using a certified (Oriel
91150V) monocrystalline silicon reference cell traceable to the
National Renewable Energy Laboratory (NREL).

Conclusions

This study shows that the position of dye anchoring points
in half-squarylium dyes influences hydrophobicity and contact angle
of dyes sorbed to TiO\textsubscript{2} surfaces. These phenomena are ascribed to
the orientation of both individual dyes on the surface and the way in
which sorbed dyes interact with each other such that hydrophobic
surfaces consist of dye monolayers with hydrophobic chains perpendicularly arranged to the surface.

Cyclic voltammetry measurements suggest the LUMO levels of
all the dyes tested should be correctly positioned to enable
electron injection from the dye excited state. However, the
position of the linker group on the chromophore does affect the
dye performance in DSC devices where improved J
values were obtained near to the squaraine linker moiety. Finally, we believe
this is the first report of the ultra-fast co-sensitization of a dye precursor (Hf-SQ with the associated full dye (squaraine)) which
is important in the context of extending spectral response whilst
minimizing dye costs. Thus, co-sensitizing with two dyes from
the same synthetic pathway reduces synthetic costs and results in
similar device performance to panchromatic squaraines reported
in the literature, which require much more complex and
expensive synthetic procedures.
