Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Structure-based design, synthesis, and biological evaluation of peptidomimetic SARS-CoV 3CLpro inhibitors

Abstract—Structure-based design, synthesis, and biological evaluation of a series of peptidomimetic severe acute respiratory syndrome-coronavirus chymotrypsin-like protease inhibitors are described. These inhibitors were designed and synthesized based upon our X-ray crystal structure of inhibitor 1 bound to SARS-CoV 3CLpro. Incorporation of Boc-Ser as the P4-ligand resulted in enhanced SARS-CoV 3CLpro inhibitory activity. Structural analysis of the inhibitor-bound X-ray structure revealed high binding affinity toward the enzyme.

Severe acute respiratory syndrome (SARS), a contagious and fatal respiratory illness, was first reported in Guangdong province, China, in November 2002.1 Its rapid and unexpected spread to other Asian countries, North America, and Europe alarmed both the public and the World Health Organization. SARS is caused by a novel coronavirus, SARS-CoV.2,3 Its emergence affected more than 8000 individuals and caused more than 800 deaths within a few months.4 This signifies just how rapidly a contagious illness can spread in the more mobile and highly interconnected world in the 21st century. Remarkably, the world has witnessed how concerted international cooperation allowed health experts to identify the novel etiologic agent and contain the SARS epidemic just months after its emergence. Currently, there is no known SARS transmission anywhere in the world. At the same time, there is no guarantee that this outbreak will not strike again in an even more severe form. Thus far, no effective therapy exists for this viral infection.

The SARS-CoV is a positive-strand RNA virus whose genome sequence reveals only moderate relation to other known coronaviruses.5 During viral replication, viral replicase polyproteins undergo extensive processing by two viral proteases, namely chymotrypsin-like protease (3CLpro) and papain-like protease (PLpro), to generate a functional viral replication complex.6,7 Therefore, both SARS-CoV 3CLpro and SARS-CoV PLpro are recognized as logical targets for therapeutic intervention against SARS-CoV and related interactions.8

The structure and activity of the SARS-CoV 3CLpro have been investigated.9 The enzyme active site contains a catalytic dyad where a cysteine residue acts as a nucleophile and a histidine residue acts as the general acid base. SARS-CoV 3CLpro is functionally analogous to the main picornaviral protease 3Cpro and there have been significant drug-design efforts against human rhinoviral 3C protease which is also a cysteine protease.10 We recently described structure-based design of a number of potent SARS-CoV 3CLpro inhibitors.11 These inhibitors were designed based upon modification of AG7088, a potent inhibitor of the human rhinoviral 3C protease.12 While AG7088 does not exhibit inhibitory activity against SARS-CoV 3CLpro, the modified
inhibitors are active in enzymatic assays as well as in cell culture assays. The X-ray structure of inhibitor-bound SARS-3CLpro revealed important molecular insight into the ligand-binding sites of enzyme. The inhibitors bind to SARS-CoV 3CLpro through covalent bonding with the active site cysteine 145 residue. Based upon this molecular insight, we have now modified our initial inhibitors to accommodate specific ligand-binding site interactions in the S$_4$-subsite of the SARS-CoV 3CLpro active site. Herein we describe the synthesis, biological evaluation, and X-ray structures of inhibitor-bound SARS-CoV 3CLpro for two potent peptide and peptidomimetic inhibitors (Fig. 1).

As described previously, inhibitor 2 makes a number of important interactions in the enzyme active site. These include, the covalent bond formed by the Cys-145 thiol with the $\alpha$,$\beta$-unsaturated ester at the S$_1$-subsite. His-172 makes hydrogen bond with the P$_1$-lactam-NH, and the Glu-166 nitrogen makes a hydrogen bond with the ketone of the inhibitor. The P$_4$-oxazole group appears to fill in the S$_4$-hydrophobic pocket. Based upon this X-ray structure, we subsequently speculated that the replacement of P$_4$-oxazole with a Boc-Serine P$_4$-ligand would promote additional hydrogen-bonding interactions in the S$_4$-site. This will result in further enhancement of inhibitory potency. We have also evaluated the corresponding peptide-derived inhibitors for our studies.

The synthesis of inhibitor 3 is outlined in Scheme 1. The synthetic procedure of silyl ether derivative 6 was described by us previously. Removal of the silyl protecting group with tetrabutylammonium fluoride in THF provided a secondary alcohol, which was oxidized to ketone 7 with the Dess–Martin periodinane in 73% yield over 2 steps. The ketone 7 was converted to inhibitor 3 by exposure to trifluoroacetic acid (20% TFA/CH$_2$Cl$_2$) followed by coupling of the resulting amine with Boc-(L)-Serine to provide 3 in 72% yield.

The syntheses of peptide-based inhibitors are summarized in Scheme 2. General peptide coupling reactions between (S)-valine and (S)-leucine or (S)-phenylalanine followed by ester hydrolysis gave the carboxylic acid intermediates 10 and 11 in 81% and 90% yields, respectively. Coupling of these acids with lactam fragment 12 afforded Boc-derivatives 13 and 14 in 89% and 86% yields, respectively. Exposure of these compounds to TFA effected the removal of the Boc-group to provide the corresponding free amines. Coupling of these amines with Boc-(L)-serine furnished inhibitors 4 and 5 in 55% and 95% yields, respectively. Furthermore, reaction of...
the 13 or 14-derived amines with 5-methylisoxazole-3-carboxylic acid 15 afforded inhibitors 16 (75%) and 17 (81%) in very good yields.

The inhibitory activities of the synthetic inhibitors are shown in Table 1. The enzyme inhibitory activity of the compounds against SARS-CoV 3CLpro was determined in a FRET-based, microplate assay described by Grum-Tokars et al. This protocol has previously been used for the determination of IC_{50} values for α,β-unsaturated esters. The assays were performed in 96-well microplates using a reaction volume of 100 μL which contained 50 mM Hepes, (pH 7.5), 500 nM SARS-CoV 3CLpro enzyme, and varying concentrations of synthetic inhibitors. The reaction components, with the exception of substrate, were incubated for 20 min and the reaction was initiated by the addition of FRET-substrate [AlexaFluo®488-cys]-Glu-Ser-Ala-Thr-Leu-Gln-Gly-Leu-Ala-[Lys-QSY®-7]-Ser, giving a final substrate concentration of 1 μM. The IC_{50} of synthetic inhibitors are shown in Table 1.

### Table 1. Structures and activity of inhibitors

| Entry | Inhibitor structure | 3CLpro, IC_{50} (μM) | Antiviral, IC_{50} (μM) |
|-------|--------------------|----------------------|-------------------------|
| 1     | ![Inhibitor 1](image1.png) | 870                  | 45                      |
| 2     | ![Inhibitor 2](image2.png) | 800                  | 70                      |
| 3     | ![Inhibitor 3](image3.png) | 80                   | 75                      |
| 4     | ![Inhibitor 4](image4.png) | 10                   | 100                     |
| 5     | ![Inhibitor 5](image5.png) | 15                   | 100                     |
| 6     | ![Inhibitor 6](image6.png) | 300                  | nd                      |
| 7     | ![Inhibitor 7](image7.png) | 200                  | nd                      |
values for inhibitors were determined by measuring the rates of reaction with increasing inhibitor concentrations. As shown in Table 1, our structure-based incorporation of P4-Boc-Ser in place of P4-oxazole in inhibitor 1 resulted in (inhibitor 3) significant enhancement of enzymatic inhibitory potency, while its antiviral activity was not improved. It exhibited antiviral activity similar to inhibitors 1 and 2. This difference of activity may be due to the presence of peptide-like features in the inhibitors. Peptide-like molecules often exhibit poor passive transcellular diffusion across cell membranes. Antiviral assays followed our previously published protocol.11,18 We have compared the binding affinity of the corresponding peptide-based inhibitors incorporating both P4-oxazole and P4-Boc Ser. Peptide-based inhibitors (4 and 5) with P2-Leu and P2-Phe have displayed 20-fold enzymatic potency enhancement over the respective inhibitors (16 and 17) containing P4-oxazole.

To obtain molecular insight into the binding properties of inhibitor 3, we determined the X-ray structure of 3-bound to SARS-CoV 3CLpro to a resolution of 1.9 Å.19 The refinement statistics and data collection are summarized in Table 2. A stereoview of the inhibitor-bound structure is shown in Figure 2. The X-ray structure reveals that the inhibitor is covalently bonded to the enzyme via a C–S bond (1.77 Å) to the active site cysteine (Cys-145). The P1'-ethyl ester carbonyl is within proximity to Thr-26 oxygen (3.38 Å). The Leu-27 side chain makes hydrophobic contacts with the P1'-ligand. Furthermore, the P1-lactam NH forms a hydrogen bond with the imidazole ring of His-163. The P3-carbonyl group of 3 forms a hydrogen bond with the NH of Glu-166. The P4-Ser side chain is within hydrogen-bonding distance of Glu 166. This may explain its enhanced binding affinity over the oxazole-bearing inhibitor 2.

In conclusion, our structure-based design strategies resulted in significant improvement of enzyme inhibitory activity against SARS-CoV 3CLpro. An X-ray structure of the 3-bound enzyme provided critical molecular insight into the ligand-binding site interactions in the active site. It appears that the P2-Boc-Ser is involved in important hydrogen-bonding interactions in the S1'-subsite. The present molecular insight will facilitate the design of more effective inhibitors. Further investigations are in progress.

19. The protein–ligand X-ray structure of 3-bound SARS-3 CLpro has been deposited in the Protein Data Bank (PDB code ID: 2QIQ). SARS-CoV 3CLpro was purified using a combination of ion-exchange, ammonium sulfate fractionation, and separation by hydrophobic interaction chromatography according to our published procedures. The refinement statistics and data collection are summarized in Table 2. Purified SARS-CoV 3CLpro was exchanged into buffer (20 mM Tris, pH 7.5, 10% glycerol, and 10 mM 2-mercaptoethanol) and concentrated to 35 mg/mL using an Amicon Centrifugal Filter, molecular weight cutoff 10,000 Da. The enzyme, at a concentration of 35 mg/mL, was incubated with 1 mM inhibitor on ice for 1 h prior to crystallization which was conducted by mixing 5 μL enzyme and 1 μL of mother liquor solution and allowing the mixture to undergo vapor diffusion against 11% PEG 20,000, 50 mM NaCl, 50 mM Na-cacodylate, pH 6.5. Single crystals grew within 3 h and were cryoprotected and flash-frozen in liquid nitrogen. X-ray data was collected using a MAR-CCD detector at SER-CAT beamline 22-BM at the Advanced Photon Source, Argonne National Laboratory. Data was indexed with HKL2000 and scaled and merged with SCALPACK (Otwinowski and Minor). The structure was determined via molecular replacement using the coordinates 2ALY from the PDB (Ghosh et al.) and refined with REFMAC from the CCP4 suite (Collaborative, 1994). R-Factors were minimized by an additional 4–5% by using 10 cycles of TLS refinement on 19 segments. The 3CLpro-compound 4 complex crystallized in space group C2121 with one molecule in the asymmetric unit with unit cell parameters of a = 108.32 Å, b = 82.22 Å, c = 53.68 Å and β = 104.7°. The structure was determined by molecular replacement using as a search model. The final Rcryst and Rfree values were 19.6% and 22.8%, respectively. The final model includes the inhibitor covalently linked to Cys145.
