Abstract
Objectives  This study was aimed at detecting feline autosomal dominant polycystic kidney disease in a population of Persian and Persian-related breeds by a molecular method in Iran.
Methods  Buccal swab samples were collected from 47 cats and examined with a touchdown PCR method. Additionally, partial sequencing was performed in two cats with bilateral renal cysts.
Results  Twenty-two cats (46.8%) were diagnosed as heterozygous for this mutation. Sequence analysis of two cats showed C to A point mutation in the PKD1 gene, as in previous studies.
Conclusions and relevance  Prevalence of this disease is high in Iran, highlighting the need for molecular screening tests before including cats in breeding programmes.

Keywords: Polycystic kidney disease; Persian cats; touchdown PCR; Iran

Accepted: 17 December 2021

Introduction
Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common life-threatening inherited disorders in cats, especially in Persian and Persian-related breeds, with a prevalence of 16–49% worldwide.1 Homozygous and heterozygous mutations are two forms of expression of feline ADPKD. Fetuses homozygous for the mutation will die before birth, whereas heterozygous cats remain clinically normal until failure of renal function occurs after a number of years (usually after 7 years of age).2,3 Affected cats have variable and unpredictable disease progression and severity.4

The marked clinical and morphological similarity of feline ADPKD to human disease and its dominant mode of inheritance suggest that this disease represents a very good model for ADPKD in humans.5 The point mutation (C to A transversion), at sequence position c.10063 in exon 29 of the PKD1 gene, results in a premature stop codon at amino acid position 3284 of the polycystin-1 (PC1) protein. The PC1 protein is encoded by the PKD1 gene and with the early occurrence of this stop codon into the corresponding mRNA transcript, about 25% of the C-terminus of this protein will not be produced.6 PC1 is a transmembrane protein that interacts with other proteins to control tube lumen size through the regulation of a number of cell behaviours; it plays a key role in tubule construction during kidney development and is likely involved in tubular renovation in adult life.7 By impairing the function of the PC1 protein, proliferation and apoptosis of renal tubular epithelial cells are enhanced and multiple fluid-filled cysts will form in the cortex and medulla of both

kidneys and occasionally in the liver, pancreas and uterus at birth.\(^8\) The chronic progressive nature of the number and size of these cysts causes irreversible damage to the renal parenchyma and can lead to chronic kidney disease (CKD) and renal failure.\(^9\)

Renal imaging was the most prominent diagnostic method until 2004 when Lyons and colleagues discovered the mutation responsible for the feline ADPKD, which was a turning point in the development of diagnostic molecular methods. Unlike humans, who have multiple genes responsible for ADPKD (PKD1, PKD2, GANAB, and DNAJB11), in cats only a mutation in the PKD1 gene responsible for ADPKD is recognised.\(^10,11\) There is no specific treatment for ADPKD; most treatment protocols are supportive and symptomatic and renal transplantation is inevitable.

No information is available on PKD1 gene sequencing in cats with ADPKD in Iran. This study aimed to investigate the prevalence of ADPKD in Persian and Persian-related breeds for the first time in Iran by a molecular method, the touchdown PCR, which is a low-cost and fast method, and identify, with specific primers, a point mutation that causes this disease.

**Materials and methods**

**Sample collection**
Forty-seven clinically healthy Persian and Persian-related cats (aged between 2 months and 7 years old) were randomly selected from the Veterinary Hospital of Small Animals at the University of Tehran. Buccal swab samples were collected for genetic analysis and placed in sterile microtubes containing 1 cc of 0.9% saline and stored at −70°C until DNA extraction.

Two cats with signs of polyuria/polydipsia were examined with ultrasound examination (linear probe 7.5 MHz, Philips, Affinity 70).

**DNA extraction**
DNA for touchdown PCR was extracted using a commercial kit (MBST Iran).

Before testing for the PKD1 gene of interest, samples were tested with a PCR that detects the glyceraldehyde-3-phosphate dehydrogenase (GAPDH) gene, to verify DNA quality by using GAPDH-F (CCTTCATTGACCTCACTACAT) and GAPDH-R (CCAAAGTTGTCATGGAGACC) primers\(^12\) producing a 400 base pair (bp) fragment in all samples.

**Touchdown PCR**
A touchdown PCR was performed to detect the PKD1 mutant gene (GenBank accession number AY612847) using PKD-F3 (AGAGGCAGACGAGGAGC) and PKD-R2 (GCCTCTGGAGAAGGAGGT) primers.\(^13\) The end of 3’ reverse primer has a single nucleotide that binds to the mutant sequence template and amplification was performed only in the presence of mutant sequences.

The final mix volume was 25µl, containing 1× PCR buffer, 1µl of primers, 2mM of MgCl\(_2\), 0.25mM of each deoxyribonucleotide triphosphate (Sinaclone), 1U of Taq DNA polymerase (Sinaclone) and 5ng of DNA sample. The initial denaturation step was 5mins in duration at 94°C, followed by 10 cycles of 1min at 94°C, 1 min at 67°C (decreasing 1°C per cycle) and 1 min at 72°C, followed by 30 cycles of 1min at 94°C, 1 min at 59°C and 1 min at 72°C, with a final extension step of 10 mins at 72°C (T100 Thermal Cycler; Bio-Rad). The reaction products were analysed by electrophoresis in 1.5% agarose gels in Tris acetate EDTA buffer, stained by ethidium bromide and visualised under UV light by producing a 277 bp fragment in samples positive for the PKD1 mutant gene.\(^14\)

**Partial sequencing**
To obtain positive controls, PCR products from DNA from two cats with bilateral renal cysts (about 6 years old) were sequenced in the forward and reverse direction. Bioneer Company performed sequencing reactions and Sanger dideoxy sequencing methods were used to obtain these sequences. The sequences were initially analysed using the NCBI/BLAST/blastn suite (https://blast.ncbi.nlm.nih.gov/Blast.cgi?CMD=Web&PAGE_TYPE=BlasHome). Multiple alignments were performed with the Mega-6 package using the neighbor-joining method with 1000 bootstrap replicates and a cladogram was drawn by likelihood method with the Kimura 2 parameter statistical model.

**Results**

**Touchdown PCR assay**
Twenty-two cats (46.8%) were diagnosed as heterozygous for the mutant gene by PCR (Figure 1).
Sequencing analysis
The sequences derived were analysed using the BLAST search program (http://blast.ncbi.nlm.nih.gov/Blast.cgi). The partial *PKD1* mutant gene sequences derived from this study were submitted to GenBank with accession numbers MT648749 and MT610887.

Phylogenetic analysis of *PKD1* mutant genes
The phylogenetic tree representing the genetic relationships of the *PKD1* mutant gene sequences showed that MT648749 and MT610887 were 100% identical. Based on the phylogenetic analysis of the mutant genes, MT648749 and MT610887 clustered with *Felis catus* clone rp86-207p24 (AC145332.48). We observed 99.83% nucleotide sequence identity (the highest) for the *PKD1* mutant genes between our isolates and *Felis catus* clone rp86-207p24 (AC145332.48) (Figure 2). Additionally, to obtain positive control samples for PCR and analyse the *PKD1* mutant gene, PCR products of two Persian cats with polycystic kidney disease were partially sequenced for the first time in Iran and the results, as in previous studies, showed a C to A transversion mutation in the *PKD1* gene. The sequencing of the *PKD1* mutant gene of these two cats, which were not siblings, were 100% identical to each other, and they were also 99.38% identical (sharing a single clade) to a sequence registered in the gene bank of the complete genome of a cat of unknown breed from the USA (Figure 2).

Discussion
The prevalence of ADPKD, especially in Persian and Persian-related breeds, has been determined in countries such as the UK (49%), Germany (43%), Australia (43%), France (42%), Slovenia (36%), Italy (41%) and Japan (40%). This study aimed to detect the prevalence of ADPKD in Persian and Persian-related breeds by molecular testing for the first time in Iran. The prevalence of ADPKD in this study was 46.8%, although our sample size was quite small (n = 47). This may be due to the lack of regular screening before including a cat in a breeding programme.

Additionally, to obtain positive control samples for PCR and analyse the *PKD1* mutant gene, PCR products of two Persian cats with polycystic kidney disease were partially sequenced for the first time in Iran and the results, as in previous studies, showed a C to A transversion mutation in the *PKD1* gene. The sequencing of the *PKD1* mutant gene of these two cats, which were not siblings, were 100% identical to each other, and they were also 99.38% identical (sharing a single clade) to a sequence registered in the gene bank of the complete genome of a cat of unknown breed from the USA (Figure 2). Using the touchdown PCR method developed by Scalon et al,14 we obtained the specific band related to the mutation in these 22 cats (277 bp). Unlike in humans with ADPKD, in whom numerous mutations in different genes have been documented, in cats only a single casual point mutation in exon 29 at position c.00163 of the *PKD1* gene has been described to date.9 In studies conducted by Kappe et al,15 Bonazzi et al16 and Lee et al,13 some cats that were diagnosed with polycystic kidney disease by ultrasonography did not have the point mutation within exon 29. This indicates that mutation in other genes, like humans, may be responsible for ADPKD in cats. Ultrasound by a skilled ultrasonographer cannot detect polycystic kidney disease until about 3 months of age. Therefore, the molecular assay offers early diagnosis as well as diagnosis in areas where ultrasound is not readily available.

Since Persian cats are currently the best human model for the autosomal dominant form of the disease, it can be
said that humans can also be a good model for this disease in cats. This could pave the way for more detailed genetic studies in cats with polycystic kidneys (especially young cats) and those without the point mutation in the PKD1 gene to investigate the possibility of other unknown genetic mutations. However, acquired causes of kidney cysts include obstruction owing to nephrolithiasis, lymphoma, chronic kidney disease with interstitial nephritis at older ages and drugs such as diphenylamine.4,15,17

Conclusions
The only way to eradicate or decrease the prevalence of this disease in the future is to exclude these heterozygous animals from breeding programmes. To help achieve this aim, low cost and fast screening tests such as touchdown PCR are needed.

Acknowledgements
The authors especially thank Dr Zahra Ziafati Kafi, who kindly contributed to this study.

Conflict of interest
The authors declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Funding
The authors disclosed receipt of the following financial support for the research, authorship, and/or publication of this article: this study was funded by the University of Tehran, Faculty of Veterinary Medicine.

Ethical approval
The work described in this manuscript involved the use of non-experimental (owned or unowned) animals. Established internationally recognised high standards (‘best practice’) of veterinary clinical care for the individual patient were always followed and/or this work involved the use of cadavers. Ethical approval from a committee was therefore not specifically required for publication in JFMS Open Reports. Although not required, where ethical approval was still obtained, it is stated in the manuscript.

Informed consent
Informed consent (verbal or written) was obtained from the owner or legal custodian of all animal(s) described in this work (experimental or non-experimental animals, including cadavers) for all procedure(s) undertaken (prospective or retrospective studies). No animals or people are identifiable within this publication, and therefore additional informed consent for publication was not required.
