K3 SURFACES WITH INVOLUTION, EQUIVARIANT ANALYTIC TORSION, AND AUTOMORPHIC FORMS ON THE MODULI SPACE IV: THE STRUCTURE OF INVARIANT

SHOUHEI MA AND KEN-ICHI YOSHIKAWA

Abstract. In [39], an holomorphic torsion invariant of K3 surfaces with involution was introduced. In this paper, we completely determine its structure as an automorphic function on the moduli space of such K3 surfaces. On every component of the moduli space, it is expressed as the product of an explicit Borcherds lift and a classical Siegel modular form. We also introduce its twisted version and give its explicit formula purely in terms of Borcherds products.

Introduction

In [39], an holomorphic torsion invariant of K3 surfaces with involution was introduced by the second-named author. The purpose of the present paper is to completely determine the structure of this invariant as a function on the moduli space of such K3 surfaces. We shall express it using Borcherds products and Siegel modular forms. Let us explain our result in detail.

A pair consisting of a K3 surface and its anti-symplectic involution is called a 2-elementary K3 surface. By Nikulin [29], the deformation type of a 2-elementary K3 surface is determined by the isometry class of the invariant lattice of the induced involution on the second integral cohomology. There exist 75 deformation types, labeled by primitive 2-elementary Lorentzian sublattices of the K3 lattice $\mathbb{L}_{K3}$. Let $M \subset \mathbb{L}_{K3}$ be one such sublattice of rank $r$. Its orthogonal complement $\Lambda = M^\perp \cap \mathbb{L}_{K3}$ is a 2-elementary lattice of signature $(2, 20 - r)$. Let $\Omega^+_\Lambda$ be the Hermitian
domain of type IV of dimension $20 - r$ associated to $\Lambda$ and let $O^+(\Lambda)$ be the index 2 subgroup of the orthogonal group of $\Lambda$ preserving $\Omega^+_\Lambda$. Via the period map, the moduli space of 2-elementary $K3$ surfaces of type $M$ is isomorphic to the quotient

$$\mathcal{M}_\Lambda^0 = (\Omega^+_\Lambda - \mathcal{D}_\Lambda)/O^+(\Lambda),$$

where $\mathcal{D}_\Lambda$ is the discriminant divisor. Hence $\mathcal{M}_\Lambda^0$ is a Zariski open subset of a modular variety of orthogonal type of dimension $20 - r$.

In [39], a holomorphic torsion invariant of 2-elementary $K3$ surfaces was defined as follows. Let $(X, \iota)$ be a 2-elementary $K3$ surface of type $M$. Write $X^\iota$ for the set of fixed points of $\iota$. Depending on $M$, $X^\iota$ is either empty or the disjoint union of smooth curves of total genus $g = g(M)$. (See [32] for a formula for $g$.) When $X^\iota$ is empty, the corresponding type is unique and is called exceptional, in which case $(X, \iota)$ is the universal covering of an Enriques surface endowed with the non-trivial covering transformation. Take an $\iota$-invariant Kähler form $\gamma$ on $X$ and a holomorphic 2-form $\eta \neq 0$ on $X$. Let $\tau_{\mathcal{Z}_\iota}(X, \gamma)(\iota)$ be the equivariant analytic torsion of $(X, \gamma)$ with respect to the $\iota$-action and let $\tau(X^\iota, \gamma|_{X^\iota})$ be the analytic torsion of $(X^\iota, \gamma|_{X^\iota})$. Then the real number

$$\tau_M(X, \iota) = \frac{1}{8} \exp \left( \sum_{\gamma \in \mathcal{M}_\Lambda^0(\iota)} \log \left( \frac{\eta \wedge \eta}{\gamma^2/2!} \cdot \frac{\text{Vol}(X, \gamma)}{\| \eta \|^2_{\mathcal{Z}_\iota}} \right) \right) \chi(\iota, \gamma|_{X^\iota})$$

depends only on the isomorphism class of $(X, \iota)$, so that it gives rise to a function $\tau_M$ on $\mathcal{M}_\Lambda^0$. The goal of this paper is to give an explicit expression of $\tau_M$ in terms of modular forms. It turns out that $\tau_M$ is expressed by two types of modular forms: Borcherds products and Siegel modular forms. Let us explain these modular forms.

Let $\rho_\Lambda : \text{Mp}_2(\mathbb{Z}) \to \text{GL}(\mathbb{C}[\Lambda])$ be the Weil representation attached to the discriminant group $A_\Lambda$ of $\Lambda$, where $\mathbb{C}[\Lambda]$ is the group ring of $A_\Lambda$. By Borcherds [8], given an $O^+(\Lambda)$-invariant elliptic modular form $f$ of type $\rho_\Lambda$ and of weight $1 - (20 - r)/2$ with integral Fourier expansion, we can take its Borcherds lift $\Psi_\Lambda(\cdot, f)$. This is a (possibly meromorphic) automorphic form for $O^+(\Lambda)$ with infinite product expansion, and its Petersson norm $\| \Psi_\Lambda(\cdot, f) \|$ descends to a function on $\mathcal{M}_\Lambda^0$. To express $\tau_M$, the Borcherds lift of the following elliptic modular form shall be used. Let $\eta(\tau)$ be the Dedekind $\eta$-function and let $\theta_{\Lambda^+}(\tau)$ be the theta series of the $A_1$-lattice. We put

$$\phi_\Lambda(\tau) = \eta(\tau)^{10} \eta(2\tau)^7 \eta(4\tau)^{-8} \theta_{\Lambda^+}(\tau)^{-10}.$$ 

This induces the following modular form of type $\rho_\Lambda$ (cf. [9], [35], [40]):

$$F_\Lambda = \sum_{\gamma \in \mathcal{M}_\Lambda^0 \setminus \text{Mp}_2(\mathbb{Z})} \phi_\Lambda|_{\gamma} \rho_\Lambda(\gamma^{-1}) e_0,$$

where $|_{\gamma}$ is the Petersson slash operator and $e_0 \in \mathbb{C}[\Lambda]$ is the vector corresponding to $0 \in A_\Lambda$. Except for two types, the Borcherds lift of $(2^{r-1} + \delta_{r,10})F_\Lambda$ shall be used in the expression of $\tau_M$, where $\delta_{r,j}$ denotes the Kronecker delta.

On the other hand, Siegel modular forms also yield functions on $\mathcal{M}_\Lambda^0$. The period map for the fixed curves of 2-elementary $K3$ surfaces induces a holomorphic map

$$J_M : \mathcal{M}_\Lambda^0 \to A_g,$$

where $A_g$ is the Siegel modular variety of degree $g$. Then the pullback of the Petersson norm of a Siegel modular form by $J_M$ is a function on $\mathcal{M}_\Lambda^0$. The following
Siegel modular forms of weights $2g+1(2g+1)$ and $2(2g-1)(2g+2)$ shall be used to express $\tau_M$:

$$\chi_g^8 = \prod_{(a,b)\text{ even}} \theta_{a,b}^8, \quad \Upsilon_g = \chi_g^8 \sum_{(a,b)\text{ even}} \theta_{a,b}^{-8},$$

where $\theta_{a,b}$ is the Riemann theta constant with even characteristic $(a, b)$. Let $\|\chi_g\|^2$ and $\|\Upsilon_g\|^2$ be their Petersson norms. Hence $J_M^*\|\chi_g\|^2$ and $J_M^*\|\Upsilon_g\|$ are functions on $\mathcal{M}_g^0$. For convenience, if $M$ is exceptional, we set $g = 1$ and $J_M^*\|\Upsilon_g\| = 1$.

The main result of this paper is the following (Theorems 8.6, 9.2, 9.4, 9.5, 9.10).

**Theorem 0.1.** Let $M \subset \mathbb{L}_{K3}$ be a primitive 2-elementary Lorentzian sublattice of rank $r$ with orthogonal complement $\Lambda$ and let $\delta \in \{0, 1\}$ be the parity of its discriminant form. Then there exists a constant $C_M > 0$ depending only on $M$ such that the following equality of functions on $\mathcal{M}_g^0$ holds:

1. If $(r, \delta) \neq (2, 0), (10, 0)$, then
   $$\tau_M^{-2g(2g+1)} = C_M \|\Psi_\Lambda(\cdot, 2g-1F_\Lambda + f_\Lambda)\| \cdot J_M^* \|\chi_g\|^2.$$

2. If $(r, \delta) = (2, 0)$ or $(10, 0)$, then
   $$\tau_M^{-(2g-1)(2g+2)} = C_M \|\Psi_\Lambda(\cdot, 2g-1F_\Lambda + f_\Lambda)\| \cdot J_M^* \|\Upsilon_g\|.$$

Here $f_\Lambda$ is the elliptic modular form of type $\rho_\Lambda$ given by $f_\Lambda = \delta_{r,10} F_\Lambda$ for $r \neq 2$ and by (9.3), (9.19) below for $r = 2$.

The majority is the case (1), which covers 67 types. The case (2) covers 8 types. The formula of (1) does not hold in case (2) because $J_M^*\chi_g$ vanishes identically there. In [39], [41], the automorphy of $\tau_M$ was proved (cf. [0.2] below), but the corresponding modular form was given explicitly only for the exceptional $M$. In [40], the elliptic modular form $F_\Lambda$ was introduced and (1) was proved for $r \geq 10$. Theorem 0.1 completes this series of work.

The invariant $\tau_M$ is also related to an invariant $\tau_{BCOV}$ of Calabi-Yau threefolds, which was introduced in [12] after the prediction of Bershadsky-Cecotti-Ooguri-Vafa [2] on the mirror symmetry at genus one. On the moduli space of Calabi-Yau threefolds of Borcea-Voisin associated to 2-elementary $K3$ surfaces of type $M$ and elliptic curves, one has the following equality of functions (cf. [22])

$$\tau_{BCOV} = C_M \tau_M^{-4} \|\eta^{24}\|^2,$$

where $C_M$ is a constant depending only on $M$. By Theorem 0.1 and (0.1), $\tau_{BCOV}$ for Borcea-Voisin threefolds of type $M$ is given by the product of the Petersson norms of the modular forms $\Psi_\Lambda, F_\Lambda$, $\chi_g$ (or $\Upsilon_g$) and $\eta$. Since $-\log \tau_{BCOV}$ is identified with the genus one string amplitude $F_1$ in B-model (cf. [3], [12]), Theorem 0.1 also gives an exact result of $F_1$ for all Borcea-Voisin threefolds.

In Theorem 0.1 the automorphic form corresponding to $\tau_M$ splits into two factors. It is natural to ask if this factorization is realized at the level of holomorphic torsion invariants of 2-elementary $K3$ surfaces. Thanks to the spin-1/2 bosonization formula [2], [11], [13], we have an affirmative answer to this question. Let us introduce the following twisted version of $\tau_M$:

$$\tau_M^{\text{spin}}(X, \iota) = \prod_{\Sigma^2 = KX, h^0(\Sigma) = 0} \left\{ \text{Vol}(X, \gamma)^{14-4\iota} \tau_{\Sigma^2}(X, \gamma)(\iota) \tau(X^\prime, \Sigma; \gamma|X^\prime)^{-2} \times \exp \left[ \frac{1}{8} \int_{X^\prime} \log \left( \frac{\eta \wedge \bar{\eta}}{\gamma^2/2!} \cdot \frac{\text{Vol}(X, \gamma)}{\|\eta\|_{L^2}^2} \right) \right] \right\},$$
where $\Sigma$ runs over all ineffective theta characteristics on $X^e$ and $\tau(X^e, \Sigma; \gamma|_{X^e})$ is the analytic torsion of $\Sigma$ with respect to $\gamma|_{X^e}$. It turns out that $\tau^{\text{spin}}_M(X, \ell)$ is independent of the choice of an $\ell$-invariant Kähler form $\gamma$ and gives rise to a function $\tau^{\text{spin}}_M$ on $\mathcal{M}_\Lambda^0$. Our second result is stated as follows (cf. Theorem 0.2):

**Theorem 0.2.** Let $\mathcal{H}_\Lambda \subset \mathcal{M}_\Lambda$ be the characteristic Heegner divisor (cf. Section 2). Then there exists a constant $C'_M > 0$ depending only on $M$ such that the following equality of functions on $\mathcal{M}_\Lambda^0 \setminus \mathcal{H}_\Lambda$ holds:

$$\tau^{\text{spin}}_M = C'_M \|\Psi_A(\cdot, 2^{g-1} F_A + f_A)\|^{-1/2}.$$  

We remark that if $\mathcal{H}_\Lambda \neq \emptyset$, then $\tau^{\text{spin}}_M$ jumps along $\mathcal{H}_\Lambda$ and thus $\tau^{\text{spin}}_M$ is a discontinuous function on $\mathcal{M}_\Lambda^0$. For an explicit relation between the constants in Theorems 0.1 and 0.2 see Section 10.2 below. After Theorem 0.2, it is very likely that $C'_M$ can be determined up to an algebraic number by an Arakelov geometric study of 2-elementary $K3$ surfaces with maximal Picard number. This subject shall be discussed elsewhere. According to Theorem 0.2, the invariant $\tau^{\text{spin}}_M$ is elliptic modular in the sense that it is the Borcherds lift of an elliptic modular form. A conceptual account for this unexpected elliptic modularity as well as the geometric meaning of the corresponding modular forms is strongly desired.

Let us explain the outline of the proof of Theorem 0.1. For the sake of simplicity, we explain only the major case $\delta = 1$. Since $\tau_M$ was determined in (40) when $g \leq 2$, we assume $3 \leq g \leq 10$. The strategy is summarized as follows:

(a) Reduce Theorem 0.1 to determining the divisor of $J^*_M \chi^8_g$.
(b) Determine the support of the divisor of $J^*_M \chi^8_g$ for certain key lattices $M_{g,0}$.
(c) Determine inductively from (b) the support of the divisor of $J^*_M \chi^8_g$ for all $M$ and prove sharp estimates for its coefficients.
(d) Deduce Theorem 0.1 from the estimates in step (c).

Let us see each step in more detail.

(a) From the theory of Quillen metrics [7], [6], [23], the automorphy of $\tau_M$ follows (39, 11): There exist $\ell \in \mathbb{Z}_{>0}$ and an automorphic form $\Phi_M$ on $\Omega^1_M$ with

$$\tau_M = \|\Phi_M\|^{-1/2}, \quad \text{wt} \Phi_M = ((r - 6)\ell, 4\ell), \quad \text{div} \Phi_M = \ell \mathcal{D}_A.$$  

(We will eventually see that $\ell$ can be taken to be $2^{g-1}(2^g + 1)$.) By construction, the automorphic form $\Psi_A(\cdot, 2^{g-1} F_A)^\ell \otimes J^*_M \chi_g^{8\ell}$ has the same weight as $\Phi_M^{2^{g-1}(2^g + 1)}$. Hence by the Koecher principle, it is sufficient to show that

$$\text{div}(\Psi_A(\cdot, 2^{g-1} F_A)^\ell \otimes J^*_M \chi_g^{8\ell}) \geq \text{div}(\Phi_M^{2^{g-1}(2^g + 1)}).$$  

The divisor of $\Psi_A(\cdot, 2^{g-1} F_A)$ is calculated by the theory of Borcherds product [8], so the problem is reduced to calculating the divisor of $J^*_M \chi^8_g$.

Since $\delta = 1$, the isometry class of $M$ is determined by $g$ and the number $k + 1$ of the components of the fixed curve. (See Section 4.2) for the formula for the invariants $g = g(M)$ and $k = k(M)$.) Write $M_{g,k}$ for the lattice with these invariants and set $\Lambda_{g,k} = M_{g,k}^\perp$. Let $\mathcal{D}_{\Lambda_{g,k}} = \mathcal{D}_{\Lambda_{g,k}}^0 + \mathcal{D}_{\Lambda_{g,k}}^1$ be the decomposition according to the type of $(-2)$-vectors of $\Lambda_{g,k}$, and let $\mathcal{H}_{\Lambda_{g,k}}$ be the characteristic Heegner divisor (cf. Section 2). We will proceed inductively on $k$.

(b) We first study the series $k = 0$ by a geometric approach (Section 6). Curves with vanishing theta constants are characterized by the existence of certain half-canonical bundle. By analyzing bi-anticanonical sections of Del Pezzo surfaces with
such property, we prove that the support of \( \text{div}(J^*_{M,g} \chi^8_g) \) on \( \mathcal{M}^0_{g,0} \) coincides with \( \mathcal{H}_{g,0} \). Hence there exist integers \( a_g, b_g, c_g \geq 0 \) such that

\[
(0.4) \quad \text{div}(J^*_{M,g} \chi^8_g) = a_g D^0_{g,0} + b_g \mathcal{H}_{g,0} + c_g D^+_{g,0}.
\]

(c) We have a natural inclusion of domains \( \Lambda_{g,k+1} \subset \Lambda_{g,k} \), which induces an inclusion of domains \( i: \Omega_{g,k+1} \hookrightarrow \Omega_{g,k} \). Then we show that \( J_{M,g,k} \circ i = J_{M,g,k+1} \) outside a locus of codimension 2 and that \( i^* \mathcal{H}_{g,k} = 2 \mathcal{H}_{g,k+1} \) and similar relation between \( D^+_{g,k} \) and \( D^+_{g,k+1} \) (cf. Sections 2 and 3). This enables us to inductively extend (0.4) to the case \( k \geq 1 \) (Section 8):

\[
\text{div}(J^*_{M,g} \chi^8_g) = a_{g,k} D^0_{g,k} + b_{g,k} \mathcal{H}_{g,k} + c_{g,k} D^+_{g,k},
\]

where \( a_{g,k}, b_{g,k}, c_{g,k} \) are integers satisfying

\[
a_{g,k} = a_g, \quad b_{g,k} = 2^k b_g, \quad c_{g,k} = 0 \quad (g < 10).
\]

By using a formula in [10] and the formula [36] for the theta null divisor on the moduli space of curves, we also prove the estimates \( a_g \geq 2^{2g-1} \) and \( b_g \geq 2^4 \).

(d) Substituting these relations and estimates in the left-hand side of (0.3), we obtain the desired inequality when \( g < 10 \). In case \( g = 10 \), an extra argument is required. See Section 8. Note that \( \mathcal{H}_A \) vanishes if \( r \geq 10 \), which explains why the proof of Theorem 0.1 is much simpler in the range \( r \geq 10 \), \( (r, \delta) \neq (10, 0) \) (cf. [10]).

This paper is organized as follows. Sections 1-5 are mainly preliminaries. In Section 6 (resp. 7), we study the even theta characteristics of the fixed curve for \( A \)-elementary lattices. Section 6 (resp. 7), we study the even theta characteristics of the fixed curve for \( A \)-elementary lattices. Section 8 (resp. 9), we prove Theorem 0.1 when \( \delta = 1 \) (resp. \( \delta = 0 \)). In Section 10, we introduce the twisted holomorphic torsion invariant \( \tau^\text{spin}_M \) and prove Theorem 1.2.

1. LATTICES

A free \( \mathbb{Z} \)-module of finite rank endowed with a non-degenerate, integral, symmetric bilinear form is called a lattice. The rank and signature of a lattice \( L \) are denoted by \( r(L) \) and \( \text{sign}(L) = (b^+ (L), b^- (L)) \), respectively. For a lattice \( L = (\mathbb{Z}^r, \langle \cdot, \cdot \rangle) \) and an integer \( k \in \mathbb{Z} \setminus \{0\} \), we define \( L(k) := (\mathbb{Z}^r, k \langle \cdot, \cdot \rangle) \). The group of isometries of \( L \) is denoted by \( O(L) \). The set of roots of \( L \) is defined as \( \Delta_L := \{ d \in L : \langle d, d \rangle = -2 \} \).

For the root systems \( A_k, D_k, E_k \), the corresponding negative-definite root lattices are denoted by \( \Lambda_k, \Pi_k, E_k \), respectively. We set \( \Lambda_1^+ := \Lambda_1(-1) \) etc. The hyperbolic plane \( \mathbb{U} \) is the even unimodular lattice of signature \((1,1)\).

For an even lattice \( L \), its dual lattice is denoted by \( L^\vee \). The finite abelian group \( A_L := L^\vee / L \) is called the discriminant group of \( L \), which is equipped with the \( \mathbb{Q}/2\mathbb{Z} \)-valued quadratic form \( q_L \) called the discriminant form and the \( \mathbb{Q}/\mathbb{Z} \)-valued bilinear form \( b_L \) called the discriminant bilinear form.

A lattice \( L \) is 2-elementary if there exists \( l \in \mathbb{Z}_{>0} \) with \( A_L \cong (\mathbb{Z}/2\mathbb{Z})^{2l} \). For a 2-elementary lattice \( L \), we set \( l(L) := \dim_{\mathbb{F}_2} A_L \). When \( L \) is an even 2-elementary lattice, the parity of \( q_L \) is denoted by \( \delta(L) \in \{0,1\} \). By Nikulin [25, Th. 3.6.2], the isometry class of an indefinite even 2-elementary lattice \( L \) is determined by the
triplet \((\text{sign}(L), l(L), \delta(L))\). For an even 2-elementary lattice \(L\), there is a unique element \(1_L \in A_L\), called the characteristic element, such that \(b_L(\gamma, 1_L) = q_L(\gamma) \mod \mathbb{Z}\) for all \(\gamma \in A_L\). Then \(g(1_L) = 1_L\) for all \(g \in O(q_L)\).

The K3-lattice is defined as the even unimodular lattice of signature \((3,19)\)
\[
L_{K3} := \mathbb{U} \oplus \mathbb{U} \oplus \mathbb{U} \oplus \mathbb{E}_8 \oplus \mathbb{E}_8.
\]
It is classical that \(L_{K3}\) is isometric to the second integral cohomology lattice of a K3 surface. For a sublattice \(\Lambda \subset L_{K3}\), we define \(\Lambda^\perp := \{ l \in L_{K3}; \langle l, \Lambda \rangle = 0 \}\).

A primitive 2-elementary Lorentzian sublattice of \(L_{K3}\) isometric to \(\mathbb{U}(2) \oplus \mathbb{E}_8(2)\) is said to be exceptional. (For the reason why this is exceptional, see §3.2.) Its orthogonal complements in \(L_{K3}\), i.e., \(\mathbb{U} \oplus \mathbb{U}(2) \oplus \mathbb{E}_8(2)\) is also said to be exceptional.

**Proposition 1.1.** The isometry classes of primitive 2-elementary sublattices \(\Lambda\) of \(L_{K3}\) with signature \((2, r(\Lambda) - 2)\) consist of the following 75 classes in Table 1 where \(g(\Lambda) := \{ r(\Lambda) - l(\Lambda) \}/2\).

| \(g\) | \(\delta = 1\) | \(\delta = 0\) |
|-----|----------------|----------------|
| 0   | \((A_1^*)^{22} \oplus A_1^{22}\) | \(0 \leq t \leq 9\) | \(\mathbb{U}(2)^{22}\) |
| 1   | \(\mathbb{U} \oplus A_1^{2} \oplus A_1^{22}\) | \(0 \leq t \leq 9\) | \(\mathbb{U} \oplus \mathbb{U}(2), \mathbb{U}(2)^{22} \oplus D_4, \mathbb{U} \oplus \mathbb{U}(2) \oplus \mathbb{E}_8(2)\) |
| 2   | \(\mathbb{U}^{22} \oplus A_1^{2}\) | \(1 \leq t \leq 9\) | \(\mathbb{U}^{22}, \mathbb{U} \oplus \mathbb{U}(2) \oplus D_4, \mathbb{U}^{22} \oplus \mathbb{E}_8(2)\) |
| 3   | \(\mathbb{U}^{22} \oplus D_4 \oplus A_1^{2}\) | \(1 \leq t \leq 6\) | \(\mathbb{U}^{22} \oplus D_4, \mathbb{U} \oplus \mathbb{U}(2) \oplus D_4^{2} \oplus D_8\) |
| 4   | \(\mathbb{U}^{22} \oplus D_6 \oplus A_1^{2}\) | \(0 \leq t \leq 5\) | \(\mathbb{U}^{22} \oplus D_4^{2}\) |
| 5   | \(\mathbb{U}^{22} \oplus E_6 \oplus A_1^{2}\) | \(0 \leq t \leq 5\) | \(\mathbb{U}^{22} \oplus D_8\) |
| 6   | \(\mathbb{U}^{22} \oplus E_8 \oplus A_1^{2}\) | \(1 \leq t \leq 5\) | \(\mathbb{U}^{22} \oplus \mathbb{E}_8, \mathbb{U}^{22} \oplus D_4 \oplus D_8\) |
| 7   | \(\mathbb{U}^{22} \oplus D_4 \oplus E_8 \oplus A_1^{2}\) | \(1 \leq t \leq 2\) | \(\mathbb{U}^{22} \oplus D_4 \oplus \mathbb{E}_8\) |
| 8   | \(\mathbb{U}^{22} \oplus D_6 \oplus E_8 \oplus A_1^{2}\) | \(0 \leq t \leq 1\) | \(\mathbb{U}^{22} \oplus D_8 \oplus \mathbb{E}_8\) |
| 9   | \(\mathbb{U}^{22} \oplus E_6 \oplus E_8 \oplus A_1^{2}\) | \(0 \leq t \leq 1\) | \(\mathbb{U}^{22} \oplus D_8 \oplus \mathbb{E}_8\) |
| 10  | \(\mathbb{U}^{22} \oplus E_8^{2} \oplus A_1\) | | \(\mathbb{U}^{22} \oplus E_8^{2}\) |

**Proof.** See e.g. [13] p.705 Table 2 and p.706 Table 3. Notice that the representative of each isometry class is not necessarily identical to the one in [13] p.705 Table 2 and p.706 Table 3.

For a primitive 2-elementary Lorentzian sublattice \(M \subset L_{K3}\) and a root \(d \in \Delta_M^\perp\), the smallest sublattice of \(L_{K3}\) containing \(M\) and \(d\) is given by
\[
[M \perp d] := (M^\perp \cap d^\perp)^\perp.
\]
Then \([M \perp d]\) is again a primitive 2-elementary Lorentzian sublattice of \(L_{K3}\) with \([M \perp d]^\perp = M^\perp \cap d^\perp\).

2. DOMAINS OF TYPE IV AND MODULAR VARIETIES OF ORTHOGONAL TYPE

In Section 2 \(\Lambda\) is assumed to be an even 2-elementary lattice with sign(\(\Lambda\)) = \((2, r(\Lambda) - 2)\). We define the complex manifold \(\Omega_\Lambda\) with projective \(O(\Lambda)\)-action by
\[
\Omega_\Lambda := \{ [x] \in \mathbb{P}(\Lambda \otimes \mathbb{C}); \langle x, x \rangle = 0, \langle x, \bar{x} \rangle > 0 \}.\]
Then $\Omega_\Lambda$ has two connected components $\Omega_\Lambda^\pm$, each of which is isomorphic to a bounded symmetric domain of type IV of dimension $r(\Lambda) - 2$. The orthogonal modular variety $\mathcal{M}_\Lambda$ associated to $\Lambda$ is defined as the analytic space

$$\mathcal{M}_\Lambda := \Omega_\Lambda/O(\Lambda) = \Omega_\Lambda^+ / O^+(\Lambda),$$

where

$$O^+(\Lambda) := \{ g \in O(\Lambda); g(\Omega_\Lambda^\pm) = \Omega_\Lambda^\pm \}.$$  

We denote by $\mathcal{M}_\Lambda^*$ the Baily–Borel–Satake compactification of $\mathcal{M}_\Lambda$, which is an irreducible normal projective variety of dimension $r(\Lambda) - 2$ with $\dim(\mathcal{M}_\Lambda^* \setminus \mathcal{M}_\Lambda) \leq 1$.

2.1. Discriminant locus. For $\lambda \in \Lambda$ with $\langle \lambda, \lambda \rangle < 0$, we define

$$H_\lambda := \{ [x] \in \Omega_\Lambda; \langle x, \lambda \rangle = 0 \}.$$  

Then $H_\lambda$ is a nonzero divisor on $\Omega_\Lambda$. For any root $d \in \Delta_\Lambda$, we have the relation

$$d = \Omega_{\Lambda^0 \cap d^\perp}. $$

The discriminant locus of $\Omega_\Lambda$ is the reduced divisor of $\Omega_\Lambda$ defined by

$$D_\Lambda := \sum_{d \in \Delta_\Lambda / \pm 1} H_d.$$  

We define the $O(\Lambda)$-invariant Zariski open subset $\Omega_\Lambda^0$ of $\Omega_\Lambda$ by

$$\Omega_\Lambda^0 := \Omega_\Lambda \setminus D_\Lambda.$$  

We set

$$\overline{D}_\Lambda := D_\Lambda / O(\Lambda), \quad \mathcal{M}_\Lambda^0 := \Omega_\Lambda^0 / O(\Lambda) = \mathcal{M}_\Lambda \setminus \overline{D}_\Lambda.$$  

2.2. Some subloci of $D_\Lambda$. We define the decomposition $\Delta_\Lambda = \Delta_\Lambda^+ \sqcup \Delta_\Lambda^-$ by

$$\Delta_\Lambda^+ := \{ d \in \Delta_\Lambda, d/2 \in \Lambda^\vee \}, \quad \Delta_\Lambda^- := \{ d \in \Delta_\Lambda, d/2 \notin \Lambda^\vee \}.$$  

Then $\Delta_\Lambda^\pm$ are $O(\Lambda)$-invariant. We define the $O(\Lambda)$-invariant reduced divisors $D_\Lambda^\pm$ on $\Omega_\Lambda$ and the corresponding divisors $\overline{D}_\Lambda^\pm$ on $\mathcal{M}_\Lambda$ by

$$D_\Lambda^\pm := \sum_{d \in \Delta_\Lambda^\pm / \pm 1} H_d, \quad \overline{D}_\Lambda^\pm := D_\Lambda^\pm / O(\Lambda).$$

**Proposition 2.1.** Let $d \in \Delta_\Lambda^+$. Then $i_*: \Omega_{\Lambda^0 \cap d^\perp} = H_d \hookrightarrow \Omega_\Lambda$ be the inclusion. Then the following equalities of divisors on $\Omega_{\Lambda^0 \cap d^\perp}$ hold:

$$i^*(D_\Lambda^+ - H_d) = D_{\Lambda^0 \cap d^\perp}^+, \quad i^*\overline{D}_\Lambda^+ = D_{\Lambda^0 \cap d^\perp}^+.$$  

**Proof.** Let $\delta \in \Delta_\Lambda \setminus \{ \pm d \}$. Then $H_d \cap H_\delta \neq \emptyset$ if and only if $L := \mathbb{Z}d + \mathbb{Z}\delta$ is negative-definite. Since the Gram matrix of $L$ with respect to the basis $\{ d, \delta \}$ is given by $-2[a_1^{\alpha}]$ where $a = -\langle \delta, d/2 \rangle \in \mathbb{Z}$, we conclude that $H_d \cap H_\delta \neq \emptyset$ if and only if $a = 0$, i.e., $\delta \in \Delta_\Lambda \cap d^\perp = \Delta_{\Lambda^0 \cap d^\perp}$. Since $\Delta_\Lambda^+ \cap d^\perp = \Delta_{\Lambda^0 \cap d^\perp}^+$, we get

$$i^*(D_\Lambda^+ - H_d) = \sum_{\delta \in \Delta_\Lambda^+ \setminus \{ \pm d/2 \} / \pm 1} i^*H_\delta = \sum_{\delta \in \Delta_{\Lambda^0 \cap d^\perp}^+ / \pm 1} i^*H_\delta = \sum_{\delta \in \Delta_{\Lambda^0 \cap d^\perp}^+ / \pm 1} H_\delta = D_{\Lambda^0 \cap d^\perp}^+,$$

$$i^*\overline{D}_\Lambda^+ = \sum_{\delta \in \Delta_\Lambda^- / \pm 1} i^*H_\delta = \sum_{\delta \in \Delta_{\Lambda^0 \cap d^\perp}^- / \pm 1} i^*H_\delta = \sum_{\delta \in \Delta_{\Lambda^0 \cap d^\perp}^- / \pm 1} H_\delta = D_{\Lambda^0 \cap d^\perp}^-.$$  

This proves the result. \hfill $\Box$

For $d \in \Delta_\Lambda$, we define a non-empty Zariski open subset $H_d^0 \subset H_d$ by
We set
\[ D_\Lambda^0 := \sum_{d \in \Delta_\Lambda^0} H_d^0, \quad D_\Lambda^0 := D_\Lambda^0^+ + D_\Lambda^0^- = \sum_{d \in \Delta_\Lambda^0} H_d^0. \]

Then \( \Omega_\Lambda^0 \cap D_\Lambda^0 \) is a Zariski open subset of \( \Omega_\Lambda \), whose complement has codimension \( \geq 2 \) when \( r(\Lambda) \geq 4 \) and is empty when \( r(\Lambda) \leq 3 \).

### 2.3. Characteristic Heegner divisor
Set \( \varepsilon_\Lambda := \{12 - r(\Lambda)\}/2 \).

We define the characteristic Heegner divisor of \( \Omega_\Lambda \) as the reduced divisor
\[ \mathcal{H}_\Lambda = \mathcal{H}_\Lambda(\varepsilon_\Lambda, 1_\Lambda) := \sum_{\lambda \in \Lambda^\vee \pm 1, \lambda^2 = \varepsilon_\Lambda, |\lambda| = 1_\Lambda} H_\lambda, \]
where \( |\lambda| := \lambda + A \in A_\Lambda \). Since \( 1_\Lambda \) is \( O(q_A) \)-invariant, \( \mathcal{H}_\Lambda \) is \( O(\Lambda) \)-invariant. Since \( \varepsilon_\Lambda \geq 0 \) when \( r(\Lambda) \leq 12 \), we get \( \mathcal{H}_\Lambda = 0 \) if \( r(\Lambda) \leq 12 \).

#### Proposition 2.2
Let \( d \in \Delta_\Lambda^+ \). Let \( i : \Omega_{\Lambda \cap d^+} \rightarrow \Omega_\Lambda \) be the inclusion. Then the following equality of divisors on \( \Omega_{\Lambda \cap d^+} \) holds
\[ i^* \mathcal{H}_\Lambda = 2 \mathcal{H}_{\Lambda \cap d^+}. \]

#### Proof
Since \( r(\Lambda) \leq 21 \), we get \( \varepsilon_\Lambda \geq -\frac{3}{2} \). Set \( \Lambda' := \Lambda \cap d^\perp \). Since \( d \in \Delta_\Lambda^+ \), we deduce from [14 Prop. 3.1] that \( \Lambda \) and \( \Lambda' \oplus Zd \) have the same invariants \((r, l, \delta)\).

Hence we get the orthogonal decomposition \( \Lambda = \Lambda' \oplus Zd \). Let \( \lambda \in \Lambda^\vee \) be such that \( \lambda^2 = \varepsilon_\Lambda \) and \( |\lambda| = 1_\Lambda \). Then we can write \( \lambda = \lambda' + a(d/2) \), where \( \lambda' \in (\Lambda')^\vee \) and \( a = -\langle \lambda, d \rangle \in Z \). Since \( |\lambda| = 1_\Lambda \), we get \( a \equiv 1 \) mod 2. Hence \( a = 2k + 1 \) for some \( k \in Z \) and \( \lambda' \in 1_{\Lambda'}. \) Since \( H_{\Lambda'} \neq \emptyset \) if and only if \( (\lambda')^2 < 0 \), we get \( i^* \mathcal{H}_{\Lambda'} = H_{\Lambda'} \neq \emptyset \) if and only if \( 0 > (\lambda')^2 = \lambda^2 + a^2/2 = (\varepsilon_\Lambda + 1/2) + 2k(k + 1) \). Since \( \varepsilon_\Lambda \geq -\frac{3}{2} \) and hence \(-2 \leq \frac{-1 - \sqrt{-2\varepsilon_\Lambda}}{2} < \frac{-1 + \sqrt{-2\varepsilon_\Lambda}}{2} \leq 1 \), we see that \( (\varepsilon_\Lambda + 1/2) + 2k(k + 1) < 0 \) if and only if \( k = 0, -1 \). This proves that
\[ \lambda = \lambda' \pm (d/2). \]

When \( \lambda = \lambda' \pm (d/2) \), we get \( (\lambda')^2 = \varepsilon_\Lambda + 1/2 = \varepsilon_{\Lambda'}. \) This, together with [22,2], yields that
\[ i^* \mathcal{H}_\Lambda = \sum_{\lambda \in \Lambda^\vee \pm 1, \lambda^2 = \varepsilon_\Lambda, |\lambda| = 1_\Lambda} i^* \mathcal{H}_\lambda = \sum_{\lambda' \in (\Lambda')^\vee \pm 1, (\lambda')^2 = \varepsilon_{\Lambda'}, |\lambda'| = 1_{\Lambda'}} i^* \mathcal{H}_{\lambda' \pm (d/2)} = 2 \sum_{\lambda' \in (\Lambda')^\vee \pm 1, (\lambda')^2 = \varepsilon_{\Lambda'}, |\lambda'| = 1_{\Lambda'}} \mathcal{H}_{\lambda'} = 2 \mathcal{H}_{\Lambda'}. \]

This proves the proposition. \( \square \)

### 3. 2-elementary K3 surfaces and the Torelli map

#### 3.1. 2-elementary K3 surfaces
A K3 surface \( X \) equipped with a holomorphic involution \( \iota : X \rightarrow X \) is called a 2-elementary K3 surface if \( \iota \) is anti-symplectic:
\[ \iota^*|_{H^0(K_X)} = -1. \]
The possible deformation types of 2-elementary \(K3\) surfaces were determined by Nikulin. (See \([1\text{ Sect. 2.3}]\) and the references therein.) Let \(\alpha: H^2(X, \mathbb{Z}) \cong \mathbb{L}_{K3}\) be an isometry of lattices. Set \(H^2(X, \mathbb{Z})_\pm := \{l \in H^2(X, \mathbb{Z}); \iota^*l = \pm l\}\) and
\[
M := \alpha(H^2(X, \mathbb{Z})_+), \quad \Lambda := M^\perp = \alpha(H^2(X, \mathbb{Z})_-).
\]
Then \(M \subset \mathbb{L}_{K3}\) must be a primitive 2-elementary Lorentzian sublattice. Conversely, for any primitive 2-elementary Lorentzian sublattice \(M \subset \mathbb{L}_{K3}\), there exists a 2-elementary \(K3\) surface with \((3.2)\). For a 2-elementary \(K3\) surface \((X, \iota)\), the isometry class of \(H^2(X, \mathbb{Z})_+\) is called the type of \((X, \iota)\). By an abuse of notation, the sublattice itself \(\alpha(H^2(X, \mathbb{Z})_+ \subset \mathbb{L}_{K3}\) is also called the type of \((X, \iota)\). Then there is a one-to-one correspondence between the deformation types of 2-elementary \(K3\) surfaces and the triplets \((r, l, \delta)\). Since the latter consists of 75 points, there exist mutually distinct 75 deformation types of 2-elementary \(K3\) surfaces. For a given primitive 2-elementary Lorentzian sublattice \(M \subset \mathbb{L}_{K3}\), the moduli space of 2-elementary \(K3\) surfaces of type \(M\) is given as follows.

Let \((X, \iota)\) be a 2-elementary \(K3\) surface of type \(M\) and let \(\alpha: H^2(X, \mathbb{Z}) \cong \mathbb{L}_{K3}\) be an isometry satisfying \((3.2)\). Since \(H^{2,0}(X, \mathbb{C}) \subset H^2(X, \mathbb{Z})_- \otimes \mathbb{C}\) by \((3.1)\), we get
\[
\pi_M(X, \iota, \alpha) := [\alpha(H^{2,0}(X, \mathbb{C}))] \in \Omega^0_M.
\]
Its \(O(\Lambda)\)-orbit is called the Griffiths period of \((X, \iota)\) and is denoted by
\[
\pi_{\Lambda}(X, \iota) := O(\Lambda) \cdot \pi_M(X, \iota, \alpha) \in M \Lambda^0_M.
\]

By \([39\ Th. 1.8], [40\ Prop. 11.2]\), the coarse moduli space of 2-elementary \(K3\) surfaces of type \(M\) is isomorphic to \(M \Lambda^0_M\) via the period map \(\pi_{\Lambda}\). In the rest of this paper, we identify the point \(\pi_{\Lambda}(X, \iota) \in M \Lambda^0_M\) with the isomorphism class of \((X, \iota)\).

### 3.2. The Torelli map for 2-elementary \(K3\) surfaces.

#### 3.2.1. The set of fixed points.

For a 2-elementary \(K3\) surface \((X, \iota)\) of type \(M\), set
\[
X^\iota := \{x \in X; \iota(x) = x\}.
\]
Then \(X^\iota = \emptyset\) if and only if \(M\) is exceptional, i.e., \(M \cong \mathbb{U}(2) \oplus \mathbb{E}_8(2)\). In this case, the quotient \(X/\iota\) is an Enriques surface and \((X, \iota)\) is the universal covering of an Enriques surface endowed with the non-trivial covering transformation. When \(M\) is non-exceptional, by Nikulin \([29\ Th. 4.2.2]\), we have
\[
X^\iota = C(g(M)) \amalg E_1 \amalg \cdots \amalg E_{k(M)}
\]
for \(M \not\cong \mathbb{U}(N) \oplus \mathbb{E}_8(2)\) (\(N = 1, 2\)) and we have \(X^\iota = C^{(1)} \amalg C^{(1)}_2\) for \(M \cong \mathbb{U} \oplus \mathbb{E}_8(2)\), where \(C(g)\) is a projective curve of genus \(g\) and \(E_i \cong \mathbb{P}^1\) and
\[
g(M) := \{22 - r(M) - l(M)\}/2, \quad k(M) := \{r(M) - l(M)\}/2.
\]
Since \(r(\Lambda) = 22 - r(M)\) and \(l(\Lambda) = l(M)\), we have the following relations
\[
g(M) = \{r(\Lambda) - l(\Lambda)\}/2, \quad k(M) = \{22 - r(\Lambda) - l(\Lambda)\}/2.
\]
As we defined \(g(\Lambda) = \{r(\Lambda) - l(\Lambda)\}/2\) in Proposition \([1]\) we have \(g(M) = g(\Lambda)\). Notice that, when \(M \cong \mathbb{U}(2) \oplus \mathbb{E}_8(2)\) and hence \(X^\iota\) is empty, \(g(M) = g(\Lambda) = 1\) has no geometric meaning.
3.2.2. The Torelli map. For $g \geq 0$, let $\mathcal{G}_g$ be the Siegel upper half-space of degree $g$ and let $\text{Sp}_{2g}(\mathbb{Z})$ be the symplectic group of degree $2g$ over $\mathbb{Z}$. We define
\[ \mathcal{A}_g := \mathcal{G}_g/\text{Sp}_{2g}(\mathbb{Z}). \]

The Satake compactification of $\mathcal{A}_g$ is denoted by $\mathcal{A}_g^*$. For a 2-elementary $K3$ surface $(X, i)$ of type $M$, the period of $X'$ is denoted by $\Omega(X') \in \mathcal{A}_{g(M)}$. We define a map $\overline{T}_M^0: M_A^0 \rightarrow \mathcal{A}_{g(M)}$ by
\[ \overline{T}_M(X, i) = \overline{T}_M(\pi_M(X, i)) := \Omega(X'). \]
Let $\Pi_\Lambda: \Omega_A \rightarrow M_A$ be the projection. The Torelli map is the $O(\Lambda)$-equivariant holomorphic map $J_M^0: \Omega_A^0 \rightarrow \mathcal{A}_{g(M)}$ defined by
\[ J_M^0 := \overline{T}_M^0 \circ \Pi_\Lambda|_{\Omega_A^0}. \]
In Theorem 3.3 below, we shall extend $J_M^0$ to a certain Zariski open subset of $\Omega_A$ containing $\Omega_A^0 \cup \Omega_M^0$ and prove its compatibility with respect to the inclusion $\Omega_{\Lambda \cap d} = H_d \rightarrow \Omega_A$ for $d \in \Delta_\Lambda$. For this, we introduce a stratification on $\Omega_A$.

3.2.3. A stratification of $\Omega_A$. For a primitive sublattice $L \subset \Lambda$ generated by $\Delta_L$, we define
\[ H_L := \bigcap_{d \in \Delta_L} H_d, \quad H_L^0 := H_L \setminus \bigcup_{d \in \Delta_L \setminus \Delta_\Lambda} H_d. \]
Then $H_L \neq \emptyset$ if and only if $L$ is negative-definite, i.e., $L$ is a root lattice. If $H_L \neq \emptyset$, then $H_L^0$ is a non-empty dense Zariski open subset of $H_L$. By definition, it is obvious that if $r(L) = r(L')$ and $L \neq L'$, then $H_L^0 \cap H_L' = \emptyset$. Set
\[ \Omega_A^k := \Pi_{L \subset \Lambda, r(L)=k} H_L^0, \quad \Omega_A^{k \geq} := \Pi_{L \subset \Lambda, r(L)=k} \Omega_A = \bigcup_{L \subset \Lambda, r(L)=k} H_L, \]
where $L$ runs over the set of all primitive root sublattices of $\Lambda$ of rank $k$. Then $\Omega_A^{k \geq}$ is a Zariski closed subset of $\Omega_A$ of pure dimension $k$, and $\Omega_A \setminus \Omega_A^{k \geq+1}$ is a dense Zariski open subset of $\Omega_A$, whose complement has codimension $k + 1$. We have
\[ \mathcal{D}_\Lambda = \Omega_A^{\geq1} = \sum_{d \in \Delta_L, \pm1} H_d, \quad \Omega_A^0 = \Omega_A \setminus \mathcal{D}_\Lambda. \]

For a root lattice $\mathbb{K}$, let $\mathbb{K}(\Lambda)$ be the set of primitive sublattices of $\Lambda$ isometric to $\mathbb{K}$. Since a root lattice of rank 2 is either $\mathbb{A}_1^{\otimes 2}$ or $\mathbb{A}_2$, we have
\[ \Omega_A^{\geq2} = (\bigcup_{L \in \mathbb{A}_1^{\otimes 2}(\Lambda)} H_L) \cup (\bigcup_{L \in \mathbb{A}_2(\Lambda)} H_L). \]

We set
\[ \mathcal{D}_A^{1+} = \bigcup_{L \in \mathbb{A}_1^{\otimes 2}(\Lambda)} H_L^0, \quad \mathcal{D}_A^{1-} = \bigcup_{L \in \mathbb{A}_2(\Lambda)} H_L^0. \]
Then $\mathcal{D}_A^{1+} \cap \mathcal{D}_A^{1-} = \Omega_A^0$ and we have the stratification
\[ \Omega_A \setminus \Omega_A^{\geq3} = \Omega_A^0 \cap \mathcal{D}_A^{1+} \cap \mathcal{D}_A^{1-} \]
such that $\mathcal{D}_A \setminus \Omega_A^{\geq3} = \mathcal{D}_A^{1+} \cap \mathcal{D}_A^{1-}$ is a divisor of $\Omega_A \setminus \Omega_A^{\geq3}$.

**Lemma 3.1.** If $d \in \Delta_\Lambda^+$, then $H_d \setminus \Omega_A^{\geq3} = \Omega_{\Lambda \cap d} \cap \mathcal{D}_{\Lambda \cap d}^0$.

**Proof.** (Step 1) By the definition of $\mathcal{D}_A^0$, we have $H_d^0 = H_d \cap \mathcal{D}_A^0$. Since $d \in \Delta_\Lambda^+$, we have $H_d \cap H_d \neq \emptyset$ for $d \in \Delta_\Lambda \setminus \{\pm d\}$ if and only if $d \in \Delta_{\Lambda \cap d}$. Hence $H_d \cap H_d^0 = H_d = H_d \setminus \bigcup_{\delta \in \Delta_{\Lambda \cap d}} H_\delta = H_d \setminus \bigcup_{\delta \in \Delta_{\Lambda \cap d}} \Omega_\delta^0 = \Omega_{\Lambda \cap d}^0$.

(Step 2) Assume $H_d \cap \mathcal{D}_A^{1-} \neq \emptyset$. Then there exist $L \in \mathbb{A}_2(\Lambda)$ and $[\eta] \in H_d \cap \mathcal{H}_L^0$. By the definition of $H_L^0$, we have $d \in \Delta_L$. Since $L \cong \mathbb{A}_2$, there exists $\delta \in \Delta_L$ with
\[ \langle d, \delta \rangle = 1. \] Since \( d \in \Delta^1_\Lambda \), this yields the contradiction \( \langle d, \delta \rangle = 2((d/2), \delta) \in 2\mathbb{Z} \). This proves \( H_d \cap D^{1+}_\Lambda = \emptyset \).

(Step 3) Assume \( H_d \cap D^{1+}_\Lambda \neq \emptyset \). Then there exists \( L \in \mathbb{A}^{\otimes 2}_1(\Lambda) \) with \([\eta] \in H_d \cap H^0_L\). By the definition of \( H^0_L \), we get \( d \in \Delta_L \). Hence \( \Delta_L = \{ \pm d, \pm \delta \} \) for some \( \delta \in \Delta_{\Lambda \cap d^{-}} \).

Thus

\[
H_d \cap D^{1+}_\Lambda = \bigcup_{L \in \mathbb{A}^{\otimes 2}_1(\Lambda), d \in L} H_d \cap H^0_L = \bigcup_{\delta \in \Delta_{\Lambda \cap d^{-}}} \{(H_d \cap H_\delta) \setminus \bigcup_{\epsilon \in \Delta \setminus \{ \pm d, \pm \delta \}} H_\epsilon = D^0_{\Lambda \cap d^{-}} \}
\]

Since \( d \in \Delta^1_\Lambda \), the third equality follows from the fact that \( H_d \cap H_\epsilon \neq \emptyset \) for \( \epsilon \in \Delta \setminus \{ \pm d \} \) if and only if \( \epsilon \in \Delta_{\Lambda \cap d^{-}} \). This proves \( H_d \cap D^{1+}_\Lambda = D^0_{\Lambda \cap d^{-}} \).

(Step 4) Since \( H_d \cap \Omega^0_\Lambda = \emptyset \), the result follows from (Steps 1-3) and (3.2.3). \( \square \)

3.2.4. The local structure of \( \Omega^0_\Lambda \) near \( D^{1+}_\Lambda \). Let \( \Delta \subset \mathbb{C} \) be the unit disc and set \( \Delta^* := \Delta \setminus \{ 0 \} \). Let \( L_0 \subset \Delta^2 \) be the diagonal locus and set \( L_1 := \{ 0 \} \setminus \Delta \) and \( L_2 := \Delta \times \{ 0 \} \). Then \( L_0, L_1, L_2 \) are lines with \( L_i \cap L_j = \{ 0 \} \) for any \( i \neq j \). We have \( \Delta^2 = \Delta^2 \setminus (L_1 \cup L_2) \). Set \( L_i^* := L_i \setminus \{ (0, 0) \} \).

**Lemma 3.2.** Let \([\eta] \in D^{1+}_\Lambda \cap D^{1-}_\Lambda \) and set \( n := \dim \Omega_\Lambda \). Then the following hold.

1. If \([\eta] \in D^{1+}_\Lambda \), then there is a neighborhood \( U \) of \([\eta] \) in \( \Omega_\Lambda \setminus \Omega^2_\Lambda \) such that
   \[
   U \cap \Omega^0_\Lambda \cong (\Delta^* \times \Delta)^{-2}, \quad U \cap D^0_\Lambda \cong (L_1 \cup L_2) \times \Delta^{-2}, \quad U \cap D^{1+}_\Lambda \cong \{ (0, 0) \} \times \Delta^{-2}.
   \]

2. If \([\eta] \in D^{1-}_\Lambda \), then there is a neighborhood \( U \) of \([\eta] \) in \( \Omega_\Lambda \setminus \Omega^2_\Lambda \) such that
   \[
   U \cap D^0_\Lambda \cong (\Delta^2 \setminus L_0) \times \Delta^{-2}, \quad U \cap D^{1+}_\Lambda \setminus D^{1-}_\Lambda \cong \Delta^{-2}.
   \]

**Proof.** Since \([\eta] \in D^{1+}_\Lambda \cap D^{1-}_\Lambda \), there exist \( L \in \mathbb{A}^{\otimes 2}_1(\Lambda) \) and \( \Lambda \) and a neighborhood \( U \) of \([\eta] \) in \( \Omega_\Lambda \setminus \Omega^2_\Lambda \) such that \( U \cap \Delta^1_\Lambda = U \cap \bigcup_{d \in \Delta_L} H_d \).

(1) Assume \([\eta] \in D^{1+}_\Lambda \). Then \( L \in \mathbb{A}^{\otimes 2}_1(\Lambda) \). There exists \( d_1, d_2 \in \Delta_L \) with \( \langle d_1, d_2 \rangle = 0 \) such that \( U \cap \Delta_L = U \cap (H_{d_1} \cup H_{d_2}) \). Replacing \( U \) by a smaller neighborhood if necessary, there exist a system of coordinates \( (z_1, z_2, w) \) on \( U \) such that \( H_{d_1} = \text{div}(z_1), H_{d_2} = \text{div}(z_2) \). The isomorphism \( \psi : (U, [\eta]) \cong (\Delta^0_\Lambda, 0) \) induced by \( (z_1, z_2, w) \) is the desired property.

(2) Assume \([\eta] \in D^{1-}_\Lambda \). Since \( L \in \mathbb{A}^2_1(\Lambda) \), there exist \( d_0, d_1, d_2 \in \Delta_L \) and \( \langle d_0, d_1 \rangle = 1 \) such that \( U \cap \Delta_L = U \cap (H_{d_0} \cup H_{d_1} \cup H_{d_2}) \). Replacing \( U \) by a smaller neighborhood if necessary, there exist a system of coordinates \( (z_1, z_2, w) \) on \( U \) such that \( H_{d_1} = \text{div}(z_1), H_{d_2} = \text{div}(z_2), H_{d_0} = \text{div}(z_1 + z_2) \). The isomorphism \( \psi : (U, [\eta]) \cong (\Delta^0_\Lambda, 0) \) induced by \( (z_1, z_2, w) \) is the desired property. \( \square \)

3.2.5. Inclusion of lattices and the Torelli map. Recall that for \( d \in \Delta^1_\Lambda \), it follows from Lemma 3.1 the equality of sets \( H_d \setminus \Omega^2_\Lambda = \Omega^1_{\Lambda \cap d^{-}} \cup D^0_{\Lambda \cap d^{-}} \). By Lemma 3.2 (1), \( \Omega^1_\Lambda \cup D^0_\Lambda \cup D^{1+}_\Lambda \) is a Zariski open subset of \( \Omega_\Lambda \setminus \Omega^2_\Lambda \).

**Theorem 3.3.** \( J^0_M \) extends to a holomorphic map from \( \Omega^0_\Lambda \cup D^0_\Lambda \cup D^{1+}_\Lambda \) to \( \mathcal{A}^0_\Lambda \).

**Proof.** Set \( n := \dim \Omega_\Lambda \). Let \([\eta] \in \mathbb{A}^0_1 \cup \mathbb{A}^{1+}_1 \). By Lemma 3.2 (1), there is a neighborhood \( U \) of \([\eta] \) in \( \Omega_\Lambda \) such that either \( U \setminus (\mathbb{A}^0_1 \cup \mathbb{A}^{1+}_1) \cong \Delta^* \times \Delta^{-1} \) or \( U \setminus (\mathbb{A}^0_1 \cup \mathbb{A}^{1+}_1) \cong (\Delta^*)^2 \times \Delta^{-2} \). By Borel 10, \( J^0_M \) extends to a holomorphic map from \( U \) to \( \mathcal{A}^0_\Lambda \). Since \([\eta] \in \mathbb{A}^0_1 \cup \mathbb{A}^{1+}_1 \) is an arbitrary point, we get the result. \( \square \)
Remark 3.4. By Lemma 3.2 (2), Borel’s extension theorem does not apply to $J^0_n$ near $D^{1-}_\Lambda$. This explains why $J_M$ does not extend to $\Omega_\Lambda \setminus \Omega^3_\Lambda$ in general.

Denote the extension of $J^0_M$ by

$$J_M : \Omega^0_\Lambda \cup D^0_\Lambda \cup D^{1+}_\Lambda \to A_g^*$$

and call it again the Torelli map. By [40, Th. 2.5], the following equality holds

$$J_M|_{H^0_d} = J_{[M \perp d]}|_{\Omega^0_{\Lambda \cap d}, \perp}$$

for all $d \in \Delta_\Lambda$. The following refinement is crucial for the proof Theorem 3.1.

Theorem 3.5. If $d \in \Delta^+_\Lambda$, then

$$J_M|_{H^0_d \setminus \Omega^3_\Lambda} = J_{[M \perp d]}|_{\Omega^0_{\Lambda \cap d}, \perp}.$$  

Proof. Since both $J_M|_{H^0_d \setminus \Omega^3_\Lambda}$ and $J_{[M \perp d]}|_{\Omega^0_{\Lambda \cap d}, \perp}$ are holomorphic maps from $\Omega^0_{\Lambda \cap d}, \perp$ to $A_g^*$ by Lemma 3.1 and Theorem 3.3, it suffices to prove the equality on $\Omega^0_{\Lambda \cap d}, \perp$. Since this was proved in [40, Th. 2.5], we get the result. \qed

3.3. Hyperelliptic linear system. This subsection is the technical basis for Sections 6 and 7. We advise the reader to skip for the moment and return when necessary. We prepare some tools to realize a given 2-elementary $K3$ surface as a double cover of $\mathbb{P}^2$ or a Hirzebruch surface.

We will use the following notation: For $n \geq 0$ let

$$F_n = \mathbb{P} (\mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1} (n))$$

be the $n$-th Hirzebruch surface, equipped with the natural projection $\pi : F_n \to \mathbb{P}^1$. When $n > 0$, denote by $\Sigma \subset F_n$ its unique $(-n)$-section. We write $L_{a,b}$ for the line bundle on $F_n$ of $\pi$-degree $a$ with $(L_{a,b}, \Sigma) = b$. In particular, we have $\pi^* \mathcal{O}_{\mathbb{P}^1} (1) \simeq L_{0,1}, \mathcal{O}_{F_n} (\Sigma) \simeq L_{1,-n}$ and $K_{F_n} \simeq L_{-2,-2+n}$.

Let $(X, s)$ be a 2-elementary $K3$ surface. A line bundle $L$ on $X$ with $(L, L) = 2d > 0$ is called hyperelliptic (31) if the linear system $|L|$ contains a smooth hyperelliptic member. In that case, $L$ is base point free and every smooth member of $|L|$ is hyperelliptic of genus $d + 1$. The associated morphism

$$\phi_L : X \to |L| \simeq \mathbb{P}^{d+1}$$

is generically two-to-one onto its image, mapping a smooth member of $|L|$ to a rational normal curve in a hyperplane of $|L|$. According to Saint-Donat (31 §5), we have the following possibilities for the image surface $\phi_L(X)$.

(I) $\phi_L(X)$ coincides with $|L| \simeq \mathbb{P}^2$: this is the case $d = 1$.

(II) $\phi_L(X)$ is a Veronese surface in $|L| \simeq \mathbb{P}^3$: this happens when $L = 2L'$ for $L' \in \text{Pic}(X)$ with $(L', L') = 2$.

(III) $\phi_L(X)$ is a rational normal scroll, that is, the embedding image of $F_n$ by a line bundle $L_{1, m}$ with $m > 0$ and $n + 2m = d$.

(IV) $\phi_L(X)$ is a cone over a rational normal curve, that is, the image of $F_d$ by the bundle $L_{1,0}$. In this case $\phi_L$ lifts to a morphism $X \to F_d$, and we must have $2 \leq d \leq 4$.

We now assume that the hyperelliptic bundle $L$ is $\iota$-invariant, in the sense that there exists an isomorphism

$$\iota^* L \simeq L.$$
Although \( \iota \) may not necessarily act on \( L \) equivariantly, it does so on the morphism (3.6). We then obtain an \( \iota \)-equivariant morphism

\[
\phi : X \to Y
\]

with \( Y = \mathbb{P}^2 \) in cases (I), (II), and \( Y = \mathbb{F}_n, \mathbb{F}_d \) in cases (III), (IV).

It will be useful to have a purely lattice-theoretic method for finding an \( \iota \)-invariant hyperelliptic bundle. This is based on the following lemmas. Denote by \( H_+ = H^2(X, \mathbb{Z})_+ \) the invariant lattice of \((X, \iota)\).

**Lemma 3.6.** Let \( L \in H_+ \) be nef with \((L, L) = 2d > 0\). Assume that

(a) there exists \( E \in \text{Pic}(X) \) with \((E, E) \geq 0\) and \((E, L) = 2\), and
(b) there is no \( F \in H_+ \) with \((F, F) = 0\) and \((F, L) = 1\).

Then \( L \) is hyperelliptic.

**Proof.** We first show that \( L \) is base point free. Otherwise, by (26) Proposition 5 the linear system \([L]\) would be of the form \([d + 1]F + \Gamma\) where \( F \) is a smooth elliptic curve and \( \Gamma \) is a \((-2)\)-curve with \((F, \Gamma) = 1\). Since \( \iota \) acts on \([L]\), the class of \( F \) is \( \iota \)-invariant and then would violate the assumption (b). Hence \( L \) is free, and a general member \( C \in [L] \) is smooth and irreducible of genus \( d + 1 \). We show that \( C \) is hyperelliptic. Since \( g(C) = 2 \) when \( d = 1 \), we may assume \( d > 1 \). Let \( E \) be a divisor as in the assumption (a). Since \( h^0(-E) = 0 \), we have \( h^0(E) \geq 2 \) by the Riemann-Roch inequality. Consider the exact sequence

\[
0 \to H^0(E - L) \to H^0(E) \to H^0(E|_C) \to \cdots
\]

Since \((E - L, L) < 0\), we have \( h^0(E - L) = 0 \) by the nefness of \( L \). Hence \( h^0(E|_C) \geq h^0(E) \geq 2 \) and \( E|_C \) gives a \( g_2^1 \) on \( C \).

The conditions (a) and (b) are purely arithmetic. To meet the nefness condition is always possible by the following.

**Lemma 3.7.** Let \( W(X) \) be the Weyl group of \( \text{Pic}(X) \) generated by the reflections with respect to \((-2)\)-vectors in \( \text{Pic}(X) \). Let \( L \in H_+ \) be a line bundle with \((L, L) \geq 0\) and \((L, L_0) > 0\) for some ample class \( L_0 \). Then there exists \( w \in W(X) \) such that \( w \circ \iota = \iota \circ w \) and \( w(L) \) is nef.

**Proof.** The same argument as in (4) Proposition 21.1 applies with few minor modification. We leave it to the reader. \( \square \)

Thus we can obtain an \( \iota \)-equivariant morphism (3.7) by just finding a vector in \( H_+ \) with the arithmetic conditions (a) and (b). The \( \iota \)-equivariant Weyl group action as in Lemma 3.7 would then carry this vector to a class of hyperelliptic bundle.

We are interested in when \( \iota \) acts by the covering transformation of \( \phi : X \to Y \), in which case \((X, \iota)\) may be recovered from \( Y \) and the branch curve of \( \phi \). Let \( g \) denote the genus of the main component of the fixed curve \( X^\iota \).

**Lemma 3.8.** The involution \( \iota \) acts trivially on \( Y \) when

1. \( g \geq 3 \) in case \( Y = \mathbb{P}^2 \).
2. \( g \geq 4 \) in case \( Y = \mathbb{P}^1 \times \mathbb{P}^1 \), and
3. \( g \geq n + 2 \) in case \( Y = \mathbb{F}_n \) with \( n > 0 \).

**Proof.** We may assume that \( g > 0 \). Let \( B \subset Y \) be the branch curve of \( \phi \), which belongs to \( |-2K_Y| \). Suppose that \( \iota \) acts nontrivially on \( Y \); then the genus \( g \) component of \( X^\iota \) is the normalization of the double cover of a curve component \( D \).
of $Y^t$ branched over $B|_D$. When $Y = \mathbb{P}^2$, $D$ must be a line and so intersects with $B$ at six points. When $Y = \mathbb{P}^1 \times \mathbb{P}^1$, $D$ is either a ruling fiber or a smooth bidegree $(1, 1)$ curve, which satisfies $(D, B) \leq 8$. Finally, let $Y = \mathbb{F}_n$ with $n > 0$. If $i$ acts nontrivially on the $(-n)$-section $\Sigma$, then $D$ is a ruling fiber so that $(D, -2K_Y) = 4$.

If $i$ acts trivially on $\Sigma$, we have $Y^t = H + \Sigma$ for a smooth $H \in |L_{1,0}|$ because $i$ must preserve every fiber of $\mathbb{F}_n$ and hence induces a non-trivial involution on every fiber. Then $(\Sigma, B) = (\Sigma, -2K_Y) \leq 2$ and $(H, B) = (H, -2K_Y) = 2n + 4$. This gives us the estimate $2g + 2 \leq (D, B) \leq 2n + 4$.

□

This criterion is coarse, but will suffice for our purpose.

4. Automorphic forms on the period domain

4.1. Siegel modular forms. Recall that the line bundle on $A_g$ associated with the automorphic factor $Sp_{2g}(\mathbb{Z}) \ni (\begin{pmatrix} A & B \\ C & D \end{pmatrix}) \mapsto \det(C\Omega + D) \in \mathcal{O}(\mathfrak{S}_g)$, $\Omega \in \mathfrak{S}_g$ is called the Hodge line bundle on $A_g$ and is denoted by $\mathcal{F}_g^{\Omega}$ in this paper. A holomorphic section of $\mathcal{F}_g^{\Omega}$ is identified with a Siegel modular form of weight $q$, and $\mathcal{F}_g^{\Omega}$ is equipped with the Hermitian metric $\| \cdot \|_{\mathcal{F}_g^{\Omega}}$ called the Petersson norm: For any Siegel modular form $S$ of weight $q$, we define $\|S(\Omega)\|_{\mathcal{F}_g^{\Omega}}^2 := (\det \Omega)^q |S(\Omega)|^2$.

In this paper, the following Siegel modular forms on $\mathfrak{S}_g$ play crucial roles:

$$\chi_g(\Omega)^g := \prod_{(a,b) \text{ even}} \theta_{a,b}(\Omega)^g,$$

$$\Upsilon_g(\Omega) := \chi_g(\Omega)^g \sum_{(a,b) \text{ even}} \theta_{a,b}(\Omega)^{-g}.$$ 

Here

$$\theta_{a,b}(\Omega) := \sum_{n \in \mathbb{Z}^g} \exp\{\pi \sqrt{-1} (n+a)\Omega(n+a) + 2\pi \sqrt{-1} (n+a)b\}$$

is the theta constant with even characteristic $(a,b)$, where $a,b \in \{0,1/2\}^g$ and $4ab \equiv 0 \mod 2$. For $g = 0$, we set $\chi_0 = \Upsilon_0 = 1$. Note that $\Upsilon_g(\Omega)$ is the elementary symmetric polynomial of degree $2g-1(2g+1) - 1 = (2g-1+1)(2g-1)$ in the even theta constants $\theta_{a,b}(\Omega)^g$. By [19] p.176 Cor. and p.182 Th. 3, $\chi_g^8$ (resp. $\Upsilon_g$) is a Siegel modular form of weight $2g+1(2g+1)$ (resp. $2(2g-1)(2g+2)$). The locus of vanishing theta null $\theta_{\text{null},g}$ is the reduced divisor on $A_g$ defined by $\chi_g$

$$\theta_{\text{null},g} := \{[\Omega] \in A_g; \chi_g(\Omega) = 0\}.$$

Lemma 4.1. There exist at least two distinct vanishing even theta constants at $\Omega \in \mathfrak{S}_g$ if and only if $\chi_g(\Omega) = \Upsilon_g(\Omega) = 0$. In particular, a smooth projective curve $C$ of genus $g$ has at least two effective even theta characteristics if and only if $\chi_g(\Omega(C)) = \Upsilon_g(\Omega(C)) = 0$.

Proof. Assume $\chi_g(\Omega) = \Upsilon_g(\Omega) = 0$. Since $\chi_g(\Omega) = 0$, there is an even pair $(a,b)$ with $\theta_{a,b}(\Omega) = 0$. Then $\Upsilon_g(\Omega) = \prod_{(c,d) \neq (a,b)} \theta_{c,d}(\Omega)^g$, where $(c,d) \in \{0,1/2\}^{2g}$ runs over all even pairs distinct from $(a,b)$. Since $\Upsilon_g(\Omega) = 0$, we get $\theta_{c,d}(\Omega) = 0$ for some even pair $(c,d) \neq (a,b)$. Thus $\theta_{a,b}(\Omega) = \theta_{c,d}(\Omega) = 0$. The converse is trivial. The second assertion follows from the Riemann singularity theorem [3] p.226. □

For the proof of Theorem [14] (2), (3), we need an estimate for the vanishing order of $\Upsilon_g$ for certain ordinary singular families of curves.
Lemma 4.2. Let $p : C \to \Delta$ be an ordinary singular family of curves of genus $g > 0$ with irreducible $C_0 := p^{-1}(0)$. Namely, $p : C \to \Delta$ is a proper surjective holomorphic function from a complex surface $C$ to the unit disc $\Delta$ without critical points on $C \setminus C_0$ and with a unique, non-degenerate critical point on $C_0$. Assume that $\chi_g(\Omega(C_t)) = 0$ and $\Upsilon_g(\Omega(C_t)) \neq 0$ for all $t \in \Delta^*$ and that $\chi_{g-1}(\Omega(C_0)) \neq 0$, where $C_0$ is the normalization of $C_0$. Then there exists $h(t) \in \mathcal{O}(\Delta)$ such that

$$
\log \| \Upsilon_g(\Omega(C_t)) \|^2 \geq (2g^2-2) \log |t|^2 + \log |h(t)|^2 + O \left( \log \log |t|^{-1} \right) \quad (t \to 0).
$$

Proof. We follow [40, Proof of Lemma 4.1]. For $\Omega \in \mathfrak{S}_g$, write $\Omega = (\hat{z}' \omega Z)$, where $z \in \mathfrak{H}$, $\omega \in \mathbb{C}^{g-1}$, $Z \in \mathfrak{S}_{g-1}$. For $t \in \Delta^*$, we can express

$$
\Omega(C_t) = \left[ \frac{\log t}{2\pi i} A + \psi(t) \right] \in \mathcal{A}_g,
$$

where $\psi(t)$ is a holomorphic function on $\Delta$ with values in complex symmetric $g \times g$-matrices such that $\psi(0) = (\omega Z \omega^\top Z_0) Z_0 \in \mathfrak{S}_{g-1}$, $\Omega(C_0) = [Z_0] \in \mathcal{A}_{g-1}$.

By the assumption $\chi_g(\Omega(C_t)) = 0$, $\Upsilon_g(\Omega(C_t)) \neq 0$ for all $t \in \Delta^*$ and Lemma 4.1. $C_t$ has a unique effective even theta characteristic for $t \in \Delta^*$. By fixing a marking of a reference curve, there is a unique even pair $(a, b)$, $a, b \in \{0, 1/2\}^2$ such that $\theta_{a,b}(\Omega(C_t)) = 0$ on $\Delta$ and $\theta_{a,d}(\Omega(C_t)) \neq 0$ on $\Delta^*$ for all even $(c, d) \neq (a, b)$. Write $a = (a_1, a_2)$ and $b = (b_1, b_2)$. If $a_1 = 0$, then we get $\theta_{a,b}(Z_0) = 0$ for the even pair $(a', b')$, $a', b' \in \{0, 1/2\}^2$ by [40, Eq. (4.4)], which contradicts the assumption $\chi_{g-1}(Z_0) = \chi_{g-1}(\Omega(C_0)) \neq 0$. Thus $a_1 = 1/2$.

By [40, Eqs. (4.3), (4.4)], there is a holomorphic function $F_{a,b}(\zeta, \omega, Z)$ such that

$$
\prod_{(c,d) \neq (a,b)} \theta_{c,d}(\Omega) = (e^{\pi i z/4})^{2(g-1)-1} F_{a,b}(e^{\pi i z/4}, \omega, Z).
$$

Hence there is a holomorphic function $\phi(\zeta, \omega, Z)$ such that

$$
\Upsilon_g(\Omega) = (e^{2\pi iz})^{2(g-1)-1} \phi(e^{\pi i z/4}, \omega, Z).
$$

Since $\Upsilon_g(\Omega)$ is a Siegel modular form and hence $\Upsilon_g(\Omega + A) = \Upsilon_g(\Omega)$, $\phi(\zeta, \omega, Z)$ is an even function in $\zeta$. There exists a holomorphic function $h(t) \in \mathcal{O}(\Delta)$ such that

$$
\Upsilon_g(\log t/2\pi i) A + \psi(t) = t^{2g^2-2} h(t).
$$

This, together with [40, (4.7)], implies the result. \qed

As a consequence of Lemma 4.2, we get the following.

Lemma 4.3. Let $M \subset \mathbb{L}_{K3}$ be a primitive 2-elementary Lorentzian sublattice and set $\Lambda = M^\perp$. Let $\gamma : \Delta \to \mathcal{M}_\Lambda$ be a holomorphic curve with $\gamma(\Delta^*) \subset \mathcal{M}_\Lambda^0$ intersecting $\mathcal{D}_\Lambda^0$ transversally at $\gamma(0) \in \mathcal{D}_\Lambda^0$. Let $\tilde{\gamma} : \Delta \to \Omega_\Lambda$ be its lift with $t(\tilde{\gamma}(t)) = \Pi_{\Lambda} \circ \gamma(t)$ and let $d \in \Delta_\Lambda^0$ be such that $\tilde{\gamma}(0) \in H_d$. If $\chi_g(J_M(\tilde{\gamma}(t))) = 0$ and $\Upsilon_g(J_M(\tilde{\gamma}(t))) \neq 0$ for all $t \in \Delta^*$ and if $\chi_{g-1}(J_{[M,1,d]}(\tilde{\gamma}(0))) \neq 0$, then

$$
\text{ord}_{t=0} \tilde{\gamma}^*(J_M \Upsilon_g) \geq 2(2g^2-1) - 1.
$$

Proof. Let $\overline{J}_M : \mathcal{M}_\Lambda^0 \cup \overline{\mathcal{D}}_\Lambda^0 \to \mathcal{A}_g^0$ be the extension of $\overline{J}_M^0 : \mathcal{M}_\Lambda^0 \to \mathcal{A}_g$. By [40, Theorem 2.3 (1), (2)], there is an ordinary singular family of curves $p : C \to \Delta$ of genus $g$ with irreducible $C_0$ and with period map $\overline{J}_M \circ \gamma$. By Lemma 4.2, we get

$$
\text{ord}_{t=0} \gamma^*(\overline{J}_M \Upsilon_g) \geq 2(2g^2-1) - 1,
$$

as required. \qed
which, together with $J_M(\gamma(t^2)) = \overline{J_M(\gamma(t))}$, yields the result. \hfill \square

4.2. Automorphic forms on $\Omega_A$. Let $M \subset \mathbb{L}_{K^3}$ be a primitive 2-elementary Lorentzian sublattice and set $\Lambda = M^\perp$ as before. Let $q \in \mathbb{Z}_{>0}$ be such that $J^q_M$ extends to a very ample line bundle on $\mathcal{A}_\Lambda$. Let $i : \Omega^0_\Lambda \cup \mathcal{D}_\Lambda^0 \hookrightarrow \Omega_A$ be the inclusion and define $\lambda^q_M$ as the trivial extension of $J^q_M$ from $\Omega^0_\Lambda \cup \mathcal{D}_\Lambda^0$ to $\Omega_A$, i.e.,

$$\lambda^q_M := i_* \mathcal{O}_\Omega \cup \mathcal{D}_\Lambda^0 \left( J^q_M \mathcal{F}^q_{g(M)} \right).$$

Since $\Omega_\Lambda \setminus (\Omega^0_\Lambda \cup \mathcal{D}_\Lambda^0)$ has codimension 2 in $\Omega_A$, $\lambda^q_M$ is an $O(\Lambda)$-equivariant invertible sheaf on $\Omega_A$. On $\Omega^0_\Lambda$, $\lambda^q_M$ is equipped with the Hermitian metric

$$\| \|_{\lambda^q_M} := J^q_M \| \|_{\mathcal{F}^q_{g}}.$$

Fix $l_{\Lambda} \in \Lambda \otimes \mathbb{R}$ with $\langle l_{\Lambda}, l_{\Lambda} \rangle \geq 0$. Define $j_A(\gamma, \cdot) \in \mathcal{O}_{\Omega_A}$, $\gamma \in O(\Lambda)$ and $K_A(\cdot) \in C^\infty(\Omega_A)$ by

$$j_A(\gamma, [\eta]) := \frac{\langle \gamma(\eta), l_{\Lambda} \rangle}{\langle \eta, l_{\Lambda} \rangle}, \quad K_A([\eta]) := \frac{\langle \eta, \overline{\eta} \rangle}{\| \eta, l_{\Lambda} \|^2}.$$

Let $p, q \in \mathbb{Z}$. Then $F \in H^0(\Omega_\Lambda, \lambda^q_M)$ is called an automorphic form on $\Omega_\Lambda$ for $O(\Lambda)$ of weight $(p, q)$ if it satisfies the following functional equation on $\Omega_\Lambda$:

$$F(\gamma \cdot [\eta]) = j_A(\gamma, [\eta])^p \gamma(F([\eta])), \quad \forall \gamma \in O(\Lambda). \tag{4.1}$$

The notion of automorphic forms on $\Omega_\Lambda^+$ for $O^+(\Lambda)$ of weight $(p, q)$ is defined in the same way. In the rest of this paper, the vector space of automorphic forms on $\Omega_\Lambda$ for $O(\Lambda)$ of weight $(p, q)$ is identified with the vector space of automorphic forms on $\Omega_\Lambda^+$ for $O^+(\Lambda)$ of weight $(p, q)$ via the restriction map

$$H^0(\Omega_\Lambda, \lambda^q_M) \owns F \mapsto F|_{\Omega_\Lambda^+} \in H^0(\Omega_\Lambda^+, \lambda^q_M).$$

We define the Petersson norm of an automorphic form $F$ on $\Omega_\Lambda$ for $O(\Lambda)$ of weight $(p, q)$ as the $O(\Lambda)$-invariant $C^\infty$ function on $\Omega^0_\Lambda$ defined as

$$\| F([\eta]) \|^2 := K_A([\eta])^p \cdot \| F([\eta]) \|^2_{\lambda^q_M}.$$

5. The invariant $\tau_M$ and its automorphic property

Let $(X, \iota)$ be a 2-elementary $K^3$ surface of type $M$. Let $\gamma$ be an $\iota$-invariant Kähler form on $X$. The Laplacian acting on $(0, q)$-forms on $X$ is denoted by $\square_{0,q}$. Write $\sigma(\square_{0,q})$ for the spectrum of $\square_{0,q}$ and $E_{0,q}(\lambda)$ for eigenspace of $\square_{0,q}$ corresponding to $\lambda \in \sigma(\square_{0,q})$. Since $\iota$ preserves $\gamma$, $\iota$ acts on $E_{0,q}(\lambda)$. The equivariant zeta function of $\square_{0,q}$ is defined as the following convergent series for $s \in \mathbb{C}$ with $\Re s > 0$:

$$\zeta_{0,q}(\iota)(s) := \sum_{\lambda \in \sigma(\square_{0,q}) \setminus \{0\}} \text{Tr}(\iota|_{E_{0,q}(\lambda)}) \lambda^{-s}.$$

Then $\zeta_{0,q}(\iota)(s)$ extends meromorphically to $\mathbb{C}$ and is holomorphic at $s = 0$. We define the equivariant analytic torsion $[6]$ of $(X, \gamma)$ as

$$\tau_{\mathbb{Z}_2}(X, \gamma)(\iota) := \exp \left[ -\sum_{q \geq 0} (-1)^q \zeta'_{0,q}(\iota)(0) \right].$$

Let $\eta \in H^0(X, K_X) \setminus \{0\}$ and set $\| \eta \|_{F^2}^2 := (2\pi)^{-2} \int_X \eta \wedge \overline{\eta}$. For a compact Kähler manifold $(V, \omega)$, define $\text{Vol}(V, \omega) := (2\pi)^{-\dim V} \int_V \omega^{\dim V}/(\dim V)!$. 

When \( X^i \neq \emptyset \), write \( X^i = \Pi_i C_i \) for the decomposition into the connected components. Let \( \tau(C_i, \gamma|_{C_i}) \) be the analytic torsion \([30]\) of \((C_i, \gamma|_{C_i})\). We define

\[
\tau(X^i, \gamma|_{X^i}) := \prod_i \tau(C_i, \gamma|_{C_i}), \quad \text{Vol}(X^i, \gamma|_{X^i}) := \prod_i \text{Vol}(C_i, \gamma|_{C_i}).
\]

When \( X^i = \emptyset \), we set \( \tau(X^i, \gamma|_{X^i}) = \text{Vol}(X^i, \gamma|_{X^i}) = 1 \). Let \( c_1(X^i, \gamma|_{X^i}) \) be the first Chern form of \((X^i, \gamma|_{X^i})\). By \([39, \text{Th. 5.7}]\), the real number

\[
\tau_M(X, \iota) := \text{Vol}(X, \gamma)^{1/2} \tau_{\mathbb{Z}}(X, \gamma)(\iota) \text{Vol}(X^i, \gamma|_{X^i}) \tau(X^i, \gamma|_{X^i}) \times \exp \left[ \frac{1}{8} \int_{X^i} \log \left( \frac{\eta \wedge \overline{\eta}}{\gamma^2/2!} \right) \right]_{c_1(X^i, \gamma|_{X^i})}
\]

is determined by the isomorphism class of \((X, \iota)\) and hence the period \( \overline{\Phi}_M(X, \iota) \).

As an application of the theory of (equivariant) Quillen metrics \([7, 6, 23]\), the automorphism of \( \tau_M \) was established.

**Theorem 5.1** \([39, 40, 41]\). There exist \( \ell \in \mathbb{Z}_{>0} \) and an automorphic form \( \Phi_M \) on \( \Omega_{\Lambda} \) for \( O(\Lambda) \) of weight \((\ell(r(M) - 6)), \ell)\) with

\[
\tau_M = \|\Phi_M\|^{-\frac{\ell}{r}}, \quad \text{div} \, \Phi_M = \ell \, D_\Lambda.
\]

In the rest of this paper, we determine \( \Phi_M \) for all \( M \). Since it was done for exceptional \( M \) in \([39]\), \( M \) is assumed to be non-exceptional in what follows.

6. THE LOCUS OF VANISHING THETA-NULL: THE CASE \( \delta = 1 \)

In the rest of this paper, for a primitive 2-elementary Lorentzian sublattice \( M \subset \mathbb{L}_{K3} \), we write \( r, l, \delta, g, k \) for \( r(M), l(M), \delta(M), g(M), k(M) \), respectively, when there is no possibility of confusion. Recall that these invariants are introduced in Sections 1 and 3.2.1. We write

\[
\Lambda = M^\perp.
\]

Let \( \mathcal{M}_g \) be the moduli space of smooth curves of genus \( g \geq 1 \). In Sections 6 and 7, we study the Torelli map \( J_M : \Omega^1_\Lambda \to A_g \) from the geometric point of view. We here view the Torelli map rather as a morphism

\[
\overline{\mathcal{M}}_g : \mathcal{M}_g^1 \to \mathcal{M}_g
\]

from the moduli space of 2-elementary \( K3 \) surfaces to that of curves, which associates to \((X, \iota)\) the genus \( g \) component of \( X^i \). Our main purpose here is to describe the inverse image of a certain geometric locus in \( \mathcal{M}_g \) as a Heegner divisor of \( \mathcal{M}_g^1 \) in a few cases. This will be the first and necessary step toward a more complete description, Theorem 9.13 which will be obtained in the final part of the paper.

Recall that the characteristic Heegner divisor \( H_\Lambda \) of \( \Omega_\Lambda \) was defined in Section 2.3 and that the theta-null divisor \( \theta_{\text{null}, g} \) of \( A_g \) was defined in Section 4.1. We denote by

\[
\overline{H_\Lambda} \subset \mathcal{M}_g
\]

the reduced algebraic divisor corresponding to \( H_\Lambda \), and

\[
\mathcal{M}'_g = \theta_{\text{null}, g} \cap \mathcal{M}_g
\]
the reduced thetanull divisor in $\mathcal{M}_g$. It is well-known that $\mathcal{M}_g^0 \subset \mathcal{M}_g$ is the locus of curves $C$ having an effective even theta characteristic, namely an effective line bundle $L$ with $L^\otimes 2 \simeq K_C$ and $h^0(L)$ even.

In the present section we treat the moduli spaces in the following two series:

- $k = 0, \delta = 1, 3 \leq g \leq 10$,
- $k = 1, 6 \leq g \leq 9$.

Notice that in the second series we have $\delta = 0$ only when $g = 6$. We shall prove the following.

**Theorem 6.1.** If $3 \leq g \leq 10$ and $(k, \delta) = (0, 1)$, the Heegner divisor $\overline{\mathcal{H}}_\Lambda$ is irreducible and the following set-theoretic equality of (reduced) divisors of $\mathcal{M}_\Lambda^0$ holds:

$$\overline{\mathcal{H}}_\Lambda^{-1}(\mathcal{M}_g^0) = \overline{\mathcal{H}}_\Lambda \cap \mathcal{M}_\Lambda^0.$$  

The same assertion also holds for the second series when $\delta = 1$, but the following weaker version will suffice for the rest of the paper.

**Proposition 6.2.** If $6 \leq g \leq 9$ and $k = 1$, $\overline{\mathcal{H}}_\Lambda(\mathcal{M}_\Lambda^0)$ is not contained in $\mathcal{M}_g^0$.

These results will be used in Section 8. Theorem 6.1 will be proved in Sections 6.1-6.3, and Proposition 6.2 in Section 6.5.

### 6.1. Proof of Theorem 6.1: the strategy.

Let us first explain the outline of the proof of Theorem 6.1, reducing it to the construction of certain elliptic curves.

As the first step we see the irreducibility of $\overline{\mathcal{H}}_\Lambda$, which holds in a wider range.

**Lemma 6.3.** When $\delta = 1$ and $r \leq 9$, $\overline{\mathcal{H}}_\Lambda$ is an irreducible divisor of $\mathcal{M}_\Lambda$.

**Proof.** This is restated as the property that vectors $l \in \Lambda^r$ with $(l, l) = \varepsilon_\Lambda$ and $|l| = 1_\Lambda$ are all equivalent under $O^+(\Lambda)$. Consider the vector $l' = 2l$ in $\Lambda$. Since $1_\Lambda$ is of order 2, $l'$ is primitive in $\Lambda$ and satisfies

$$\text{div}(l') = 2, \quad |l'/\text{div}(l')| = 1_\Lambda \in A_\Lambda, \quad (l', l') = 4\varepsilon_\Lambda.$$  

When $(r, l) \neq (9, 9)$, the lattice $\Lambda$ contains $U \oplus U$, and then we can resort to the Eichler criterion (cf. [32]) which says that the $O^+(\Lambda)$-equivalence class of a primitive vector $l' \in \Lambda$ depends only on the norm $(l', l')$ and the element $|l'/\text{div}(l')| \in A_\Lambda$. Hence the above vectors $l' = 2l$ are all $O^+(\Lambda)$-equivalent. When $(r, l) = (9, 9)$, $\overline{\mathcal{H}}_\Lambda$ is defined by $(-2)$-vectors $l' \in \Lambda$ with $\Lambda = Zl' \oplus (l')\perp$. The isometry class of $(l')\perp$ is uniquely determined by [23], namely $(l')\perp \simeq U\oplus Z$. So that these $(-2)$-vectors $l'$ are all $O^+(\Lambda)$-equivalent.

With the irreducibility of $\overline{\mathcal{H}}_\Lambda$ verified, the proof of Theorem 6.1 is reduced to showing the non-emptiness of $\overline{\mathcal{H}}_\Lambda^{-1}(\mathcal{M}_g^0)$ and the inclusion

$$\overline{\mathcal{H}}_\Lambda^{-1}(\mathcal{M}_g^0) \subset \overline{\mathcal{H}}_\Lambda.$$  

We only need to verify (6.1) outside a locus of codimension $\geq 2$ of $\mathcal{M}_\Lambda^0$. Our approach will be based on the following geometric observation.

**Proposition 6.4.** Let $(X, i)$ be a 2-elementary $K3$ surface. If $X$ has a smooth elliptic curve $E$ with $E + i(E) \sim X^t$, then the period of $(X, i)$ is contained in the Heegner divisor $\overline{\mathcal{H}}_\Lambda$.
Proof. Let $H_\pm$ denote the $\iota$-(anti-)invariant lattices of $(X, \iota)$. The cycle $D_\pm := E \pm \iota(E)$ is contained in $H_\pm$ respectively. We shall show that $D_-$ satisfies

$$D_-, D_- = 2r - 20, \quad D_-/2 \in H'_-, \quad [D_-/2] = 1_{H_-} \in A_{H_-}. \quad (6.2)$$

The presence of such an anti-invariant cycle in the Picard lattice means that the period of $(X, \iota)$ lies in $\mathcal{P}_A$.

Since $E$ is an elliptic curve and hence its class in $H^2(X, \mathbb{Z})$ is isotropic, the first equality of $(6.2)$ follows from Lemma 6.5.

To see the last equality of $(6.2)$, we note that the anti-isometry $\lambda : A_{H_+} \to A_{H_-}$ induced from the relation $H_+ = (H_-)^2 \cap H^2(X, \mathbb{Z})$ maps $[D_+/2]$ to $[D_-/2]$ because $D_+/2 + D_-/2 = E$ is contained in $H^2(X, \mathbb{Z})$. Since $[D_+/2]$ is the characteristic element of $A_{H_+}$ by Lemma 6.5 below, so is $[D_-/2]$ in $A_{H_-}$. □

Lemma 6.5. For any 2-elementary K3 surface $(X, \iota)$ the element $[X'/2] \in A_{H_+}$ is the characteristic element.

Proof. Let $f : X \to Y$ be the quotient map by $\iota$, and let $B \subset Y$ be the branch curve. Every element of the dual lattice $H'_+$ can be written as $f^*L/2$ for some $L \in \text{Pic}(Y)$. Then

$$(X'/2, f^*(L/2)) = (B, L)/4 = (-K_Y, L)/2.$$

We can see that $(L + K_Y, L) \in 2\mathbb{Z}$ from the Riemann-Roch formula. Therefore

$$(X'/2, f^*(L/2)) \equiv (L, L)/2 = (f^*(L/2), f^*(L/2)) \mod \mathbb{Z},$$

which means that $X'/2 \in H'_+$ and that $[X'/2]$ is characteristic. □

In Sections 6.2 and 6.3, we will construct an elliptic curve $E$ as in Proposition 6.4. The non-emptiness of $\mathcal{P}_{A_+}(\mathcal{M}_g)$ will be seen in the course of proof.

6.2. Proof of Theorem 6.1: the case $g = 3$. We begin with the case $g = 3$. Recall that a smooth curve of genus 3 has an effective even theta characteristic precisely when it is hyperelliptic. So let $(X, \iota)$ be a 2-elementary K3 surface with $(g, k) = (3, 0)$ such that $X'$ is hyperelliptic. Consider the degree 4 line bundle $L = \mathcal{O}_X(X')$, which is hyperelliptic in the sense of Section 6.3. By Saint-Donat’s classification, $L$ defines a degree 2 morphism

$$\phi : X \to Q$$

onto a quadric $Q \subset \mathbb{P}^3$. We may assume that $L$ is ample, because the locus where $X'$ is hyperelliptic and $\mathcal{O}_X(X')$ is non-ample has codimension $\geq 2$ in $\mathcal{M}_A^0$. In that case $Q$ is smooth.

Claim 6.6. $\iota$ acts on $Q$ by switching the two rulings on it.

Proof. First note that $\iota$ acts on $Q$ nontrivially, for the branch curve of $\phi$ is a member of $|-2K_Q|$ and hence has genus 9. Then $\iota$ fixes the curve $\phi(X')$, which by the definition of $\iota$ has bidegree $(1, 1)$. It is easily verified that any non-trivial involution of $Q$ fixing a smooth bidegree $(1, 1)$ curve must switch the two rulings. □
We choose a ruling line $l$ on $Q$ and put $E = \phi^*l$. Then $E$ is a smooth elliptic curve on $X$ for a general choice of $l$ and satisfies the linear equivalence

$$E + \iota(E) \sim \phi^*\mathcal{O}_Q(1, 1) \sim X^*.$$ 

By Proposition 6.4 we get the inclusion $(6.1)$.

The non-emptiness of $\mathcal{P}_X^L(2\mathcal{M}_P^3)$ can be seen by reversing this construction: choose a bidegree $(4, 4)$ curve $B \subset P^1 \times P^1$ preserved by the switch involution of $P^1 \times P^1$ and take the double cover $X \to P^1 \times P^1$ branched over $B$. The switch involution can be lifted to $X$ so that its fixed curve is the preimage of the diagonal of $P^1 \times P^1$, which is hyperelliptic of genus 3. Thus Theorem 6.1 is proved in case $g = 3$. □

6.3. Proof of Theorem 6.1. the case $4 \leq g \leq 10$. We next treat the case $4 \leq g \leq 10$ in Theorem 6.1. Let $(X, \iota)$ be a $2$-elementary $K3$ surface with $4 \leq g \leq 10$, $k = 0$ and $\delta = 1$. Let $Y = X/\iota$ be the quotient surface and $C \subset Y$ be the branch $-2K_Y$-curve. The quotient map $X \to Y$ gives the canonical identification

$$C \simeq X^i.$$ 

The anti-canonical model $\bar{Y} \subset P^{g-1}$ of $Y$ is a Gorenstein del Pezzo surface of degree $g-1$, and $Y$ is its minimal resolution. Note that if $X \to \bar{X}$ is the contraction of $(-2)$-curves disjoint from $X^i$, we naturally have $Y \simeq \bar{X}/\iota$. We may view $C$ also as lying on the smooth locus of $\bar{Y}$. By the adjunction formula we have $-K_Y|_C \simeq K_C$, and the restriction map $| - K_Y| \to |K_C|$ is isomorphic because $h^0(K_Y) = h^1(K_Y) = 0$. Therefore the composition of inclusions

$$C \subset \bar{Y} \subset P^{g-1}$$

gives the canonical embedding of $C$, and we can identify $P^{g-1}$ with $|K_C|^\vee$. This also shows that $C$ is non-hyperelliptic.

Lemma 6.7. If $C$ has an effective even theta characteristic $L$, then $h^0(L) = 2$.

Proof. If $h^0(L) \neq 2$, then $h^0(L) \geq 4$. By Clifford’s theorem we have

$$6 \leq 2\dim|L| < \deg(L) = g - 1.$$ 

This holds only when $g \geq 8$ and $h^0(L) = 4$. Actually the case $g = 8$ can be excluded because a blow-down of $Y$ presents $C$ as a plane sextic with two double points and hence $C$ has Clifford index 2. The case $g = 10$, where $C$ is a smooth plane sextic, is treated in [3] Exercise VI. B-3. In case $g = 9$, presenting $C$ as plane sextic with a node or cusp, we can argue similarly. □

Proposition 6.8. There exists a locus $Z \subset \mathcal{M}_X^1$ of codimension $\geq 2$ with the following property: When $(X, \iota)$ lies outside $Z$, the curve $C$ has a theta characteristic $L$ with $h^0(L) = 2$ if and only if $C$ can be cut out from $\bar{Y}$ by a quadric $Q \subset P^{g-1}$ of rank 3. In this case, $L$ is base point free.

Proof. (Step 1) Assume that $C \subset \bar{Y}$ is cut out by a quadric $Q$ of rank 3. The vertex of $Q$, a $(g - 4)$-plane, is disjoint from $\bar{Y}$; otherwise $C$ would be singular. The pencil of $(g - 3)$-planes in $Q$ gives $C$ a theta characteristic $L$ with $h^0(L) \geq 2$, which is free because $C$ is disjoint from the vertex. We have $h^0(L) = 2$, for $|L| = |K_C - L|$ is identified with the linear system of hyperplanes of $P^{g-1}$ containing a $(g - 3)$-plane, which is a pencil.
Choose a basis $\alpha, \beta \in H^0(K_C) = H^0(\mathcal{O}_{\mathbb{P}^{p-1}}(1))$, then $C$ is contained in the rank 3 quadric $Q \subset \mathbb{P}^{p-1}$ defined by $u_1u_2 = u_3^2$. The vertex of $Q$ is the $(g-4)$-plane $V$ defined (set-theoretically) by $(u_1 = u_2 = 0) \cap Q$. The free part $|L_0|$ is given by the pencil of $(g-3)$-planes in $Q$ through $V$, and the fixed part $D_0$ is defined by
\[ 2D_0 = (u_1 = u_2 = 0)|_C. \]
In order to show that this quadric $Q$ cuts out $C$ from $\tilde{Y}$, it suffices to prove $\tilde{Y} \not\subset Q$, for then $C$ and $Q|_Y$ are both $-2K_Y$-curves on $\tilde{Y}$.

(Step 2) Conversely, suppose that $C$ has a complete half-canonical pencil $|L|$. Choose a basis $\alpha, \beta$ of $H^0(L)$ and write $|L| = |L_0| + D_0$ with $|L_0|$ the free part and $D_0$ the fixed part. The divisor $D_0$ is defined by $\alpha = \beta = 0$. If we set
\[ u_1 = \alpha^2, \quad u_2 = \beta^2, \quad u_3 = \alpha \beta \in H^0(K_C) = H^0(\mathcal{O}_{\mathbb{P}^{p-1}}(1)), \]
then $C$ is contained in the rank 3 quadric $Q \subset \mathbb{P}^{p-1}$ defined by $u_1u_2 = u_3^2$. The vertex of $Q$ is the $(g-4)$-plane $V$ defined (set-theoretically) by $(u_1 = u_2 = 0) \cap Q$. The free part $|L_0|$ is given by the pencil of $(g-3)$-planes in $Q$ through $V$, and the fixed part $D_0$ is defined by
\[ 2D_0 = (u_1 = u_2 = 0)|_C. \]

In order to show that this quadric $Q$ cuts out $C$ from $\tilde{Y}$, it suffices to prove $\tilde{Y} \not\subset Q$, for then $C$ and $Q|_Y$ are both $-2K_Y$-curves on $\tilde{Y}$.

(Step 3) Suppose the contrary: $\tilde{Y} \subset Q$. We then have three linearly independent sections $\tilde{u}_1, \tilde{u}_2, \tilde{u}_3 \in H^0(-K_Y)$ on $Y$ with $\tilde{u}_1\tilde{u}_2 = \tilde{u}_3^2$ and $u_1 = \tilde{u}_1|_C$. Choose a blow-down $\pi : Y \to \mathbb{P}^2$ and let $Z \subset \mathbb{P}^2$ be the blown-up points (which possibly contain infinitely near ones). We have $\#Z = 10 - g$. The image $\pi(C)$ of $C$ is a plane sextic having double points at $Z$ and no other singularities. Via the mapping
\[ | - K_Y | \to |\mathcal{O}_{\mathbb{P}^2}(3)|, \quad D \mapsto \pi(D), \]
we can identify $| - K_Y |$ with the linear system of plane cubics through $Z$, and $D$ is recovered from $\Gamma = \pi(D)$ by $D = \pi^*\Gamma - \pi^{-1}(Z)$. Now by our assumption $\tilde{u}_1\tilde{u}_2 = \tilde{u}_3^2$, the divisors of $\tilde{u}_1, \tilde{u}_2, \tilde{u}_3$ correspond to three linearly independent cubics $\Gamma_1, \Gamma_2, \Gamma_3$ with $\Gamma_1 + \Gamma_2 = 2\Gamma_3$. This equality can hold only when
\[ \Gamma_1 = 2l_1 + l, \quad \Gamma_2 = 2l_2 + l, \quad \Gamma_3 = l_1 + l_2 + l \]
for some distinct lines $l_1, l_2, l$. Let $p = l_1 \cap l_2$. The net spanned by $\Gamma_1, \Gamma_2, \Gamma_3$ consists of splitting cubics $l + l' + l''$ where $l', l''$ are lines through $p$. In particular, its base locus is $p \cup l$. Recall that the restriction of this net to $C$, after the transformation
\[ (6.3) \quad |P(u_1, u_2, u_3)| = \mathcal{O}^{Sym^2H^0(L)}(\mathbb{P}^2), \]
we also denote $E = \pi^{-1}(p)$. We observe the following:

1. $Z$ lies on $p \cup l$;
2. $p \in Z$ and $p \notin l$;
3. the free part $|L_0|$ is given by the projection from $p$;
4. the fixed part $D_0$ is given by
\[ 2D_0 = (\hat{l} + E)|_C. \]

(1) is obvious. We can see (3) by noticing that $\phi_{L_0} : C \to \mathbb{P}^1$ coincides with the projection from $p$ after composing them with the conic embedding $\mathbb{P}^1 \hookrightarrow \mathbb{P}^2$, the composition being the resolution of the rational map defined by $Sym^2H^0(L)$. Under (2), we have $\text{div}(\tilde{u}_i) = 2\hat{l}_i + E + \hat{l}$ for $i = 1, 2$, so that (4) follows from (6.3). It remains to see (2). Firstly, if $p \notin \pi(C)$, then $L_0 \sim \pi^*\mathcal{O}_{\mathbb{P}^2}(1)|_C$ which is absurd. If $p \in \pi(C)$ but $p \notin Z = \text{Sing}(\pi(C))$, then $L_0 \sim \pi^*\mathcal{O}_{\mathbb{P}^2}(1)|_C - \pi^{-1}(p)$ by (3) and $D_0 \equiv \pi^{-1}(p)$ by (6.3). It follows that $L \geq \pi^*\mathcal{O}_{\mathbb{P}^2}(1)|_C$, and hence $\dim |L| \geq 2$, a contradiction. Therefore $p \in Z$. Next assume $p \in l \cap Z$. Then both $\Gamma_1$ and $\Gamma_2$ have multiplicity 3 at $p$, so that $\text{div}(\tilde{u}_i) = 2\hat{l}_i + 2E + \hat{l}$ for $i = 1, 2$. Then $2D_0 = (2E + \hat{l})|_C$ by (6.3). Since $L_0 \sim \pi^*\mathcal{O}_{\mathbb{P}^2}(1)|_C - E|_C$ by (3), we have $L \geq \pi^*\mathcal{O}_{\mathbb{P}^2}(1)|_C$, the same contradiction as before. This verifies (2).
(Step 5) Now since the $9 - g$ points $Z \backslash p$ lie on $l$ and since no four points of $Z$ can be collinear by the nefness of $-K_Y$, we must have $|Z \backslash p| \leq 3$ and thus $6 \leq g \leq 9$. The right hand side of (6.6) is divisible by 2 only if $\pi(C)$ is totally tangent to $l$ outside $Z = \text{Sing}(\pi(C))$ and $\pi(C)$ has a cusp at $p$. The cusp condition defines a divisor in the moduli space; when $7 \leq g \leq 9$ (resp. $g = 6$), the tangency condition (resp. the collinear condition on the three points $Z \backslash p$) defines another divisor. These two divisors, both Heegner and irreducible, defines a codimension 2 locus $Z$ in the moduli space. If $(X, \iota) \notin Z$, then (6.6) cannot hold and thus $\bar{Y} \not\subset Q$. By (Step 2), this implies that $C$ is cut out from $\bar{Y}$ by $Q$ when $(X, \iota) \notin Z$. □

Since the intersection of a general Del Pezzo surface $Y \subset \mathbf{P}^{g - 1}$ and a quadric $Q \subset \mathbf{P}^{g - 1}$ of rank 3 is a smooth curve, we see the non-emptiness of $\overline{n}^{1}(\mathcal{M}_g)$.

Now let $C \subset \bar{Y}$ be cut out by a quadric $Q$ of rank 3. We take the double cover
\[ \pi : \bar{Q} \rightarrow \mathbf{P}^{g - 1} \]
branched over $Q$. The (contracted) quotient map $\bar{X} \rightarrow \bar{Y}$ by $\iota$ can be identified with the restriction $\pi^{-1}(\bar{Y}) \rightarrow \bar{Y}$ of $\pi$. We again denote by $\iota$ the covering transformation of $\pi : \bar{Q} \rightarrow \mathbf{P}^{g - 1}$. We also view $\bar{X} \subset \mathbf{P}^{g}$ naturally. Note that $\bar{Q}$ is a quadric of rank 4 in $\mathbf{P}^{g}$ and hence is the cone over a smooth quadric surface $Q_0 \cong \mathbf{P}^{1} \times \mathbf{P}^{1}$ with vertex $\mathbf{P}^{g - 4}$. Let $f : \bar{Q} \rightarrow Q_0$ be the projection from the vertex. Then the pencils $f^*|\mathcal{O}_{Q_0}(1, 0)|$ and $f^*|\mathcal{O}_{Q_0}(0, 1)|$ are $\mathbf{P}^{1}$-families of $(g - 2)$-planes that sweep out $\bar{Q}$. As is easily verified, $\iota$ switches these two rulings. Restricted to $\bar{X} = \pi^{-1}(\bar{Y})$, the pencil $f^*|\mathcal{O}_{Q_0}(1, 0)|$ induces an elliptic fibration on $X$, say $|E|$. The cycle $E + \iota(E)$ is a hyperplane section of $\bar{X} \subset \mathbf{P}^{g}$. On the other hand, $X^i \subset \bar{X}$ is the ramification divisor of $\bar{X} \rightarrow \bar{Y}$ and hence also cut out by a hyperplane of $\mathbf{P}^{g}$. Therefore $E + \iota(E)$ is linearly equivalent to $X^i$ on $X$. By Proposition 6.4 and Theorem 6.1 is proved in case $4 \leq g \leq 10$. □

Remark 6.9. In the above construction, the given half-canonical pencil on $C \cong X^i$ coincides with the restriction of the elliptic fibration $|E|$: this follows because $|E|$ is the restriction of a $\mathbf{P}^{g - 2}$-ruling on $\bar{Q}$, which in turn is a component in the pullback of the family of hyperplanes in $\mathbf{P}^{g - 1}$ that cut out doubly from $Q$ the $\mathbf{P}^{g - 3}$-ruling.

Remark 6.10. A general member of $\overline{n}^{1}(\mathcal{M}_g)$ has a unique effective even theta characteristic, because the period of those $(X, \iota)$ having several elliptic curve classes $|E|$ with $E + \iota(E) \sim X^i$ lie in (the image of) the intersection of at least two components of $\mathcal{H}_A$.

6.4. Trigonal curves. This section is preliminaries for the subsequent Sections 6.5 and 7. A smooth projective curve $C$ of genus $g \geq 5$ is said to be trigonal if it has a degree 3 morphism to $\mathbf{P}^{1}$. Such a morphism, if exists, is unique up to $\text{Aut}(\mathbf{P}^{1})$. Let us summarize some properties of trigonal curves (cf. [25]).

It is classically known that a trigonal curve $C$ can be canonically embedded in a Hirzebruch surface. This is due to the fact that the canonical model of $C$ is contained in a unique rational normal scroll, namely the image of a Hirzebruch surface $F_n$ by a bundle $L_{1,m}$ with $m > 0$ (see Section 3.3 for the notation). The integer $n$ is called the scroll invariant, and $m$ the Maroni invariant of $C$. As a curve on $F_n$, $C$ belongs to the linear system $|L_{3,b}|$ with $b = m - n + 2$ by the adjunction formula. The trigonal map of $C$ is given by the restriction of the projection $F_n \rightarrow \mathbf{P}^{1}$. We have the genus formula $g = 3n + 2b - 2$, which gives the relation of $n$ and $m$. These (equivalent) invariants give a stratification of the
Lemma 6.12, \(C\) has no effective even theta characteristic: indeed, according to \([3\] p.211\) we have

\[\text{Then our assertion follows from the classical fact that any smooth plane quintic has no fixed point other than} \quad O\]

Then our assertion follows from the classical fact that any smooth plane quintic has no fixed point other than \(O\).

Proposition 6.11 (Maroni). Let \(T = L_{0,1}^\perp C\) be the trigonal bundle and write \(W_+ = rT + W_{g-1-3r}(C)\), where \(W_{g-1-3r}(C) := W_0^{g-1-3r}(C)\). Then

\[W_{g-1}^+(C) = W_+ + (K_C - W_+).\]

Using this description, we can give a geometric characterization of trigonal curves having effective theta characteristics.

Lemma 6.12. A trigonal curve \(C\) of scroll invariant \(n\) and Maroni invariant \(m\) has a theta characteristic \(L\) with \(h^0(L) \geq r + 1\) if and only if there exists a curve \(H \in |L_{1,m-2r}|^\perp\) on \(F_n\) such that \(H|_C = 2D\) for a divisor \(D\) of degree \(g - 1 - 3r\) on \(C\). In that case, the divisor \(rT + D\) gives such a theta characteristic.

Proof. A line bundle \(L\) is a theta characteristic with \(h^0(L) \geq r + 1\) if and only if it is a fixed point of the residual involution on \(W_{g-1}(C)\). Such \(L\) should be contained in \(W_+ \cap (K_C - W_+)\) by Proposition 6.11 so we can write \(L = rT + D\) for some \(D \in W_{g-1-3r}(C)\). Since \(L \sim K_C - L\), we have \(2D \sim K_C - 2rT\). The restriction map \(|L_{1,m-2r}| \rightarrow |K_C - 2rT|\) is isomorphic because \(h^1(K_{F_n} - L_{0,2r}) = 0\) for \(i = 0, 1\). Thus there exists \(H \in |L_{1,m-2r}|^\perp\) with \(H|_C = 2D\). Conversely, if we have such \(H\) and \(D\), then \(L = rT + D\) is a theta characteristic with \(h^0(L) \geq r + 1\) by Proposition 6.11.

6.5. Proof of Proposition 6.2. We shall show that a general member \(C\) of \(\overline{\mathcal{M}}_A(\mathcal{M}_g^0)\) has no effective even theta characteristic when \(k = 1\) and \(6 \leq g \leq 9\), using the description of \(C\) given in [24].

We first consider the case \(\delta = 1\), where \(6 \leq g \leq 9\). In this case \(C\) is a general trigonal curve of genus \(g\) with Maroni invariant 2, which can be realized as a general member of the linear system \(|L_{3,10-g}|\) on \(F_{g-6}\) [24 Corollaries 6.2 and 7.6]. By Lemma 6.12 \(C\) has a theta characteristic \(L\) with \(h^0(L) \geq 2\) if and only if there exists a curve \(H \in |L_{1,0}|^\perp\) totally bitangent to \(C\). However, it is readily seen that a general member of \(|L_{3,10-g}|\) has no such tangent curve.

When \(\delta = 0\), we have \(g = 6\). In this case \(C\) is a plane quintic [24 Corollary 7.3]. Then our assertion follows from the classical fact that any smooth plane quintic has no effective even theta characteristic: indeed, according to [9] p.211 we have

\[W_3^0(C) = \{ \mathcal{O}_C(p - q) \otimes \mathcal{O}_{\mathbb{P}^2}(1) \mid p, q \in C \}.\]

The residual involution acts on this \(W_3^0(C)\) by switching \(p\) and \(q\). It has no fixed point other than \(\mathcal{O}_{\mathbb{P}^2}(1)|_C\), which is an odd theta characteristic. Thus Proposition 6.2 is proved.

7. The locus of vanishing theta-null: the case \(\delta = 0\)

We continue the geometric study of the Torelli map, still viewed as a morphism \(\overline{\mathcal{M}}_A : \mathcal{M}_g^0 \to \mathcal{M}_g\) between the moduli spaces. In this section we treat the following two series:

- \(r = 2, \delta = 0\) \((g = 9, 10)\),
• \(r = 10, \delta = 0, 4 \leq g \leq 6\).

In these cases, \(\mathfrak{M}_\Lambda(\mathcal{M}_\Lambda^g)\) is contained in \(\mathfrak{M}_g^r\) because a general member of \(\mathfrak{M}_\Lambda(\mathcal{M}_\Lambda^g)\) possesses a rather apparent effective even theta characteristic.

For the first series, we will show that an analogue of Theorem 6.1 holds by replacing \(\mathfrak{M}_g^r\) with the (reduced) divisor \(\mathfrak{M}_g^r := \text{div}(\Upsilon_g) \cap \mathfrak{M}_g^r\) of \(\mathfrak{M}_g^r\), where \(\Upsilon_g\) is the Siegel modular form introduced in Section 4.1. Geometrically this locus parametrizes curves having at least two effective even theta characteristics. (See Lemma 4.1.)

**Proposition 7.1.** When \((r, \delta) = (2, 0)\) and \(g = 10\), the Heegner divisor \(\mathfrak{H}_\Lambda\) is irreducible and equal to \(\mu_\Lambda^{-1}(\mathfrak{M}_g^9)\). In particular, the genus 10 component of \(X^i\) has a unique effective even theta characteristic if the period of \((X, i)\) lies outside \(\mathfrak{H}_\Lambda\).

In case \((r, l, \delta) = (2, 2, 0)\), the Heegner divisor \(\mathfrak{H}_\Lambda\) is reducible, reflecting the fact that norm \(-4\) vectors \(l \in \Lambda\) are divided into two classes according to whether \(\text{div}(l) = 1\) or 2. We accordingly write \(\mathfrak{H}_\Lambda = \mathfrak{H}_1 + \mathfrak{H}_2\).

**Proposition 7.2.** When \((r, \delta) = (2, 0)\) and \(g = 9\), the component \(\mathfrak{H}_1\) is irreducible and equal to \(\mu_\Lambda^{-1}(\mathfrak{M}_g^8)\). In particular, \(X^i\) has a unique effective even theta characteristic if the period of \((X, i)\) lies outside \(\mathfrak{H}_\Lambda\).

For the second series, we will prove the following.

**Lemma 7.3.** If \((r, \delta) = (10, 0)\) and \(g = 4, 5\), then \(\mathfrak{M}_\Lambda(\mathcal{M}_\Lambda^g)\) is not contained in the hyperelliptic locus.

**Lemma 7.4.** If \((r, \delta) = (10, 0)\) and \(g = 6\), then a general member of \(\mathfrak{M}_\Lambda(\mathcal{M}_\Lambda^g)\) has exactly one effective even theta characteristic.

In Section 9 these results will be used to prove Theorem 0.1 (2), (3). Lemmas 7.3 and 7.4 will be strengthened in Corollary 9.14 by an argument of modular form (a geometric proof is also possible).

**7.1. Proof of Proposition 7.1.** The line of the proof of Proposition 7.1 (and 7.2) is similar to Theorem 6.1. We begin by checking the irreducibility of the Heegner divisor \(\mathfrak{H}_\Lambda\), which is defined by norm \(-4\) vectors in \(\Lambda\).

**Lemma 7.5.** When \((r, l, \delta) = (2, 0, 0)\), \(\mathfrak{H}_\Lambda\) is irreducible.

**Proof.** Since \(\Lambda \simeq \mathbb{Z}^2 \oplus \mathbb{E}^0\) is unimodular, by the Eichler criterion the \(O^+(\Lambda)\)-equivalence class of a primitive vector of \(\Lambda\) is determined by its norm. \(\square\)

We describe the members of \(\mathcal{M}_\Lambda^g\) following the construction in Section 6.1 of [22]. We consider curves on the Hirzebruch surface \(\mathcal{F}_4\). Let \(U \subset |L_{3,0}|\) be the open locus of smooth curves. We have a morphism \(p: U \to \mathcal{M}_\Lambda^0\) by associating to \(C \in U\) the double cover of \(\mathcal{F}_4\) branched over \(C + \Sigma\).

**Lemma 7.6.** There exists a geometric quotient \(U/\text{Aut}(\mathcal{F}_4)\) and the period map \(p\) descends to a biregular isomorphism \(\mathcal{P}: U/\text{Aut}(\mathcal{F}_4) \to \mathcal{M}_\Lambda^0\). In particular, the Torelli map \(\mathcal{M}_\Lambda^0 \to \mathfrak{M}_g\) is given by \(\mathcal{P}^{-1}\) and is injective, with the image the trigonal locus of Maroni invariant 2.
Proof. The $p$-fibers are the $\text{Aut}(F_4)$-orbits because the $\text{Aut}(F_4)$-orbits correspond to the isomorphism classes of trigonal curves of Maroni invariant 2, and the Torelli map recovers these isomorphism classes. Since $\mathcal{M}_A^0$ is normal, then Proposition 0.2 tells that the image of $p$ is identified with the geometric quotient of $U$ by $\text{Aut}(F_4)$. It remains to show the surjectivity of $p$.

Let $(X,\iota)$ be an arbitrary member of $\mathcal{M}_A^0$, and let $\{e,f\}$ be the natural hyperbolic basis of its invariant lattice $H_{\perp} \simeq U$. The vector $2(e+f)$ satisfies the arithmetic conditions in Lemma 3.6 and hence gives an $\iota$-invariant hyperelliptic bundle of degree 8. This defines a generically two-to-one morphism $X \to Y$ where $Y = \mathbb{P}^2$ or $F_{2n}$ with $n \leq 2$, on which $\iota$ acts by the covering transformation by Lemma 3.8. Among these possibilities of $Y$, the branch $-2K_Y$-curve can contain a component of genus 10 only when $Y = \mathbb{P}^2$ or $F_4$. The case $Y = \mathbb{P}^2$ cannot happen because it would be $(\tau,\eta,\delta) = (1,1,1)$ in that case. Hence $Y = F_4$. Since $-2K_{F_4} = \Sigma + |L_{3,0}|$ and since $L_{3,0}$ has arithmetic genus 10, the branch curve should be of the form $\Sigma + C$ with smooth $C \in |L_{3,0}|$. Thus $(X,\iota) = p(C)$. \hfill $\Box$

Let $C$ be a member of $U$. Since $C$ is disjoint from $\Sigma$, the bundle $L_{1,-4}|_C$ is trivial so that $K_C \simeq L_{1,2}|_C \simeq L_{0,6}|_C$. Hence $L_{0,3}|_C$ is a theta characteristic with $h^0(L_{0,3}|_C) = 4$. This shows that $\pi_\Lambda(\mathcal{M}_A^0) \subset \mathfrak{W}'$. We are interested in the locus $\pi_\Lambda(\mathcal{M}_A^0) \cap \mathfrak{W}''$ where $C$ has another effective even theta characteristic.

Lemma 7.7. The curve $C$ has an effective even theta characteristic different from $L_{0,3}|_C$ if and only if there exists a smooth member $H$ of $|L_{1,0}|$ such that $H|_C = 2D$ for some divisor $D$ of degree 6 on $C$.

Proof. By Lemma 6.12 $C$ has a theta characteristic $L$ with $h^0(L) \geq 2$ if and only if there exists $H \in |L_{1,0}|$ with $H|_C$ divisible by 2, in which case $L$ is given by $(H|_C)/2 + L_{0,1}|_C$. If $H$ is singular, it contains $\Sigma$ as a component and hence can be written as $H = \Sigma + \sum_{i=1}^4 F_i$ for some $L_{0,1}$-fibers $F_1,\cdots,F_4$. Since $H|_C = \sum_{i=1}^4 F_i|_C$, after renumbering we must have $F_1 = F_2$ and $F_3 = F_4$. Thus $L = L_{0,3}|_C$ in this case. \hfill $\Box$

We can now complete the proof of Proposition 7.1. Since $\pi_\Lambda(\mathcal{M}_A^0) \subset \mathfrak{W}'$, the inverse image $\pi_\Lambda^{-1}(\mathfrak{W}'')$ is a divisor in $\mathcal{M}_A^0$. It can be easily checked with Lemma 7.7 that $\pi_\Lambda(\mathcal{M}_A^0) \cap \mathfrak{W}'$ is non-empty. Hence it remains to prove the inclusion $\pi_\Lambda^{-1}(\mathfrak{W}'') \subset \overline{\mathcal{H}}_A$. Let $(X,\iota)$ be a 2-elementary $K3$ surface with $(g,k) = (10,1)$ such that $\pi_\Lambda(X,\iota) \in \mathfrak{W}''$. By Lemmas 7.6 and 7.7, we have $(X,\iota) = p(C)$ for a curve $C$ as in Lemma 7.7. Let $H$ be a smooth $L_{1,0}$-curve with $H|_C$ divisible by 2. The pullback of $H$ by the covering map $\pi : X \to F_4$ splits into two $(-2)$-curves: $\pi^*H = E + \iota(E)$. Therefore $X$ has the $\iota$-anti-invariant cycle

$$D_\pm = E - \iota(E)$$

of norm $-16$. Let $H_- \subset H^2(X,\mathbb{Z})$ be the anti-invariant lattice of $(X,\iota)$. Since

$$(D_-,H_-) = (D_- + E + \iota(E),H_-) = 2(E,H_-) \subset 2\mathbb{Z}$$

and since $H_-$ is unimodular, $D_-$ is divisible by 2 in $H_-$. Therefore $\text{Pic}(X)$ contains the anti-invariant cycle $D_-/2$ of norm $-4$, which implies that the period of $(X,\iota)$ lies in $\overline{\mathcal{H}}_A$. This proves Proposition 7.1. \hfill $\Box$
7.2. Proof of Proposition 7.2. In this subsection we prove Proposition 7.2. We first explain the decomposition of the Heegner divisor $\mathcal{H}_\Lambda$. Recall that $\mathcal{H}_\Lambda$ is defined by norm $-4$ vectors $l$ in $\Lambda \simeq \mathbb{U} \oplus \mathbb{U}(2) \oplus \mathbb{E}^2$. Since $\Lambda$ cannot contain $(-4)$ as an orthogonal direct summand, we have either $\text{div}(l) = 1$ or $2$. By the Eichler criterion, each type of norm $-4$ vectors consist of a single $O_0^+(\Lambda)$-orbit (in case $\text{div}(l) = 2$, $[l/2] \in A_\Lambda$ is the unique element of norm $\equiv 1 \mod 2\mathbb{Z}$). We accordingly obtain the decomposition

$$\mathcal{H}_\Lambda = \mathcal{H}_1 + \mathcal{H}_2$$

where $\mathcal{H}_l$ is defined by those $l$ with $\text{div}(l) = i$, and each $\mathcal{H}_i$ is irreducible.

We next recall a (well-known) construction of members of $\mathcal{M}_\Lambda^0$. Let $\hat{U}$ be the parameter space of smooth $(2,4)$ complete intersections in $\mathbb{P}^3$. For each $C \in \hat{U}$ the quadric containing it is unique; $\hat{U}$ is thus stratified according to whether the quadric is smooth or a quadratic cone. In the first case $C$ is a smooth bidegree $(4,4)$ curve on $Y = \mathbb{P}^1 \times \mathbb{P}^1$, and in the latter case $C$ is a smooth $L_{4,0}$-curve on $Y = \mathbb{F}_2$. We have a period map $p : \hat{U} \to \mathcal{M}_\Lambda^0$ by associating to $C$ the double cover of $Y$ branched over $C$.

**Lemma 7.8.** The period map $p$ descends to a biregular isomorphism $\hat{U}/\text{PGL}_4 \to \mathcal{M}_\Lambda^0$ from the geometric quotient $\hat{U}/\text{PGL}_4$.

**Proof.** This is similar to Lemma 7.6 so we only indicate minimal ingredients of the argument: (1) using the natural norm 4 vector in the invariant lattice $\mathbb{U}(2)$, we can realize a given $(X,\iota)$ as a double cover of a quadric so that $p$ is surjective; (2) the $p$-fibers are PGL$_4$-orbits either by an argument modeled in Section 4.3 of [22] or by observing that the PGL$_4$-orbits correspond to the isomorphism classes of curves (cf. [3] Exercise IV. F-2).

In the proof of Proposition 7.2 we restrict ourselves to the generic case, namely the smooth quadric case. The quadratic cone case can be dealt with similarly. So let $Y = \mathbb{P}^1 \times \mathbb{P}^1$ and consider the open locus $U \subset |\mathcal{O}_Y(4,4)|$ of smooth bidegree $(4,4)$ curves. If $C \in U$, then $K_C \simeq \mathcal{O}_Y(2,2)|_C$ and the restriction map $|\mathcal{O}_Y(2,2)| \to |K_C|$ is isomorphic. In particular, an effective divisor $D$ of degree 8 on $C$ satisfies $2D \sim K_C$ if and only if there exists a bidegree $(2,2)$ curve $H$ on $Y$ with $H|_C = 2D$. We have only one apparent theta characteristic, $\mathcal{O}_Y(1,1)|_C$, which has $h^0 = 4$. This is the case where $H$ is a double bidegree $(1,1)$ curve. By [3] Exercise IV. F-2, any other effective even theta characteristic of $C$, if exist, must satisfy $h^0 = 2$.

Now let $V \subset U$ be the locus where $C$ has a theta characteristic with $h^0 = 2$. By the same argument as in Section 7.1 the proof of Proposition 7.2 is reduced to showing the inclusion $p(V) \subset \mathcal{H}_1$. So let $C \in V$ and $(X,\iota) = p(C)$. We write $\pi : X \to Y$ for the covering map. The curve $C$ admits a 1-dimensional family $\{H_t\}_{t \in \mathbb{P}^1}$ of “totally tangent” curves of bidegree $(2,2)$, i.e., $H_t|_C = 2D_t$ for some divisors $D_t$ of degree 8 on $C$, which are not double bidegree $(1,1)$ curves. Then $\{D_t\}_{t \in \mathbb{P}^1}$ is a (complete) half-canonical pencil of $C$. Note that this pencil can also be obtained by picking up $t = 0$ and considering the linear system of bidegree $(2,2)$ curves passing through $D_0$, which intersect $C$ at $D_0 + D_t$.

**Claim 7.9.** A general member of $\{H_t\}_{t \in \mathbb{P}^1}$ is smooth.

**Proof.** If $H_t$ is reducible, its irreducible components are smooth rational curves intersecting $C$ transversely at at most two points and tangent to $C$ elsewhere. Their pullback to $X$ split into two $(-2)$-curves. So if a general member is reducible, then
the K3 surface $X$ would be covered by rational curves, which is absurd. By the same reason, a general (irreducible) member cannot be singular. \qed

Let $H$ be a general member of $\{H_1\}_{t \in P^1}$. Since $H$ is totally tangent to $C$ at 8 points, its pullback to $X$ splits into two smooth elliptic curves: $\pi^*H = E + \iota(E)$. Hence $(X,\iota)$ possesses the $\iota$-anti-invariant cycle of norm $-16$:

$$D_- = E - \iota(E).$$

**Claim 7.10.** $D_-$ is divisible by 2 in the anti-invariant lattice $H_-$ and satisfies $(D_-/2, H_-) = \mathbf{Z}$.

**Proof.** Since $D_-/2 = E - \pi^*O_Y(1,1)$ is contained in $H^2(X,\mathbf{Z})$, we have $D_-/2 \in H_-$. If $(D_-/2, H_-) \neq \mathbf{Z}$, then $(D_-/2, H_-) \subset 2\mathbf{Z}$ so that $D_-/4$ would be contained in the dual lattice $H^\vee_2$. Recall that the discriminant forms $A_{H_+}$ and $A_{H_-}$ are isometric to $A_U(2)$. As elements of $A_{H_+}$ and $A_{H_-}$, $[D_-/4]$ and $[\pi^*O_Y(1,1)/2]$ are respectively the unique elements of norm $\equiv 1 \mod 2\mathbf{Z}$. By Nikulin [28], then $E/2 = D_-/4 + \pi^*O_Y(1,1)/2$ would be contained in $H^2(X,\mathbf{Z})$. This contradicts the well-known fact that the class of a smooth elliptic curve is primitive in Pic$(X)$.

To sum up, if a smooth bidegree $(4,4)$ curve $C \subset Y$ has a theta characteristic with $h^0 = 2$, then the associated 2-elementary K3 surface $(X,\iota)$ has an anti-invariant cycle $D_-/2$ of norm $-4$ and with $(D_-/2, H_-) = \mathbf{Z}$ in its Picard lattice. Hence the period of $(X,\iota)$ lies in the component $\overline{H}_1$ of $\overline{H}_A$. This finishes the proof of Proposition 7.2. \qed

### 7.3. Proof of Lemmas 7.3 and 7.4

Lemma 7.3 is an immediate consequence of the following known description of general members of $\overline{M}_A(\mathcal{M}_3^3)$. When $g = 4$, they are general curves in $\mathcal{M}_4^4$ by [22, Cor. 9.10]; when $g = 5$, they are general trigonal curves with vanishing thetanull by Kondō [21]. Since these curves are not hyperelliptic, Lemma 7.3 follows.

For the proof of Lemma 7.4 we use the generic description given in [22, Cor. 7.11]. Let $C$ be a smooth curve on $\mathbf{P}_2$ belonging to the linear system $|L_{3,1}|$ such that the $L_{0,1}$-fiber $F$ through the point $C \cap \Sigma$ intersects $C$ with multiplicity 3 there. By taking the resolution of the double cover of $\mathbf{P}_2$ branched over $C + F + \Sigma$, we obtain a 2-elementary K3 surface with $(r, l, \delta) = (10, 0, 0)$. This construction covers general members of $\mathcal{M}_3^3$, so a general member of $\overline{M}_A(\mathcal{M}_3^3)$ is a curve $C$ as above.

Denote $p := C \cap \Sigma$ and $T := L_{0,1}|_C$. Since

$$K_C \simeq L_{1,1}|_C \sim 3T + \Sigma|_C \sim 2T + 4p,$$

the divisor $T + 2p$ gives a theta characteristic of $C$ with $h^0(T + 2p) \geq 2$. By Lemma 5.12 we have $h^0(T + 2p) = 2$. Conversely, suppose we have a theta characteristic $L$ on $C$ with $h^0(L) \geq 2$. By Lemma 6.12 we can find a curve $H \in |L_{1,-1}|$ with $H|_C = 2D$ for some divisor $D$ satisfying $L \sim T + D$. Since $|L_{1,-1}| = \Sigma + |L_{0,1}|$, $H$ is of the form $H = \Sigma + F'$ for some $F' \in |L_{0,1}|$. The condition $(\Sigma + F')|_C = 2D$ forces $F'$ to pass through $p = \Sigma \cap C$. Therefore $F = F'$ and $2D = 4p$. Thus $L$ is uniquely determined as $L \sim T + 2p$. This proves Lemma 7.4. \qed

### 8. The structure of $\tau_M$: the case $\delta = 1$

In Section 8 we determine the structure of $\Phi_M$ when $\delta = 1$. 
8.1. Borcherds products for 2-elementary lattices. Recall that the Dedekind \( \eta \)-function and the Jacobi theta series \( \theta_{\Lambda_+^{\ell}}(\tau) \), \( \ell = 0, 1 \) are the holomorphic functions on the complex upper half-plane \( \mathcal{H} \)
\[
\eta(\tau) := q^{1/24} \prod_{n=1}^{\infty} (1 - q^n), \quad \theta_{\Lambda_+^{\ell}}(\tau) := \sum_{m \in \mathbb{Z} + \ell/2} q^m, \quad q := e^{2\pi i \tau}.
\]

Let \( \Lambda \subset \mathbb{L}_{K3} \) be a primitive 2-elementary sublattice of signature \( (2, r(\Lambda) - 2) \). We set
\[
\phi_{\Lambda}(\tau) := \eta(\tau)^{-8} \eta(2\tau)^8 \eta(4\tau)^{-8} \theta_{\Lambda_+}^{\ell}(\tau)^{12 - r(\Lambda)},
\]
\[
\psi_{\Lambda}(\tau) := -16\eta(2\tau)^{-16} \eta(4\tau)^8 \theta_{\Lambda_+}^{\ell/2}(\tau)^{12 - r(\Lambda)}.
\]

Let \( \{e_i\}_{i \in A_\Lambda} \) be the standard basis of the group ring \( \mathbb{C}[A_\Lambda] \). For \( 0 \leq j \leq 3 \), set \( v_j := \sum_{\gamma \in A_\Lambda, q_\Lambda(\gamma) = j/2} e_\gamma \). By \([40, \text{Eq.}(7.9)]\), the principal part of \( F_\Lambda(\tau) \) is given by
\[
\begin{align*}
\{q^{-1} + 2(16 - r(\Lambda))\} e_0 + 2^{g(\Lambda) + 1} \{16 - r(\Lambda)\} v_0 + 2^{3g(\Lambda)} q^{-\frac{1}{2}} v_3 - 2^{16 - r(\Lambda)} q^{12 - r(\Lambda)} \{1 + (28 - r(\Lambda)) q^2\} e_{1_\Lambda}.
\end{align*}
\]

Let \( \ell \in \mathbb{Z}_{>0} \) be such that \( 2^{r(\Lambda) - 16} | \ell \) for all \( \Lambda \). Then \( \ell F_\Lambda(\tau) \) has integral Fourier expansion at \( +i\infty \). Define \( \Psi_\Lambda^\ell \) as the Borcherds lift of \( \ell F_\Lambda(\tau) \) (cf. \([8, \text{Th.}13.3]\)):
\[
\Psi_\Lambda^\ell := \Psi_\Lambda(\cdot, \ell F_\Lambda).
\]

If \( r(\Lambda) \leq 16 \), then \( \Psi_\Lambda(\cdot, F_\Lambda) \) is well defined and \( \Psi_\Lambda^\ell = \Psi_\Lambda(\cdot, \ell F_\Lambda) = \Psi_\Lambda(\cdot, F_\Lambda)^\ell \) in the ordinary sense. Since \( O(\Lambda) \) preserves \( F_\Lambda \) by \([40, \text{Th.}7.7 \{2\}]\), \( \Psi_\Lambda^\ell \) is an automorphic form on \( \Omega_\Lambda \) for \( O^+(\Lambda) \) by \([8, \text{Th.}13.3]\). Recall that the divisors \( D_\Lambda^+ \), \( D_\Lambda^- \) and \( \mathcal{H}_\Lambda \) were introduced in Sections \( 2.2 \) and \( 2.3 \).

**Theorem 8.1.** The weight and the divisor of \( \Psi_\Lambda^\ell \) are given as follows:

1. If \( r(\Lambda) \leq 20 \), then
   \[
   \begin{align*}
   \text{wt}(\Psi_\Lambda^\ell) &= \begin{cases} 
   (16 - r(\Lambda))(2^{g(\Lambda)} + 1)\ell & \text{if } r(\Lambda) \neq 12, 20, \\
   (16 - r(\Lambda))(2^{g(\Lambda)} + 1)\ell - 8(1 - \delta(\Lambda))\ell & \text{if } r(\Lambda) = 12, \\
   (16 - r(\Lambda))(2^{g(\Lambda)} + 1)\ell - (28 - r(\Lambda))2^{15 - r(\Lambda)}(1 - \delta(\Lambda))\ell & \text{if } r(\Lambda) = 20,
   \end{cases} \\
   \text{div}(\Psi_\Lambda^\ell) &= \ell \{ D_\Lambda^+ + (2^{g(\Lambda)} + 1) D_\Lambda^- - 2^{16 - r(\Lambda)} \mathcal{H}_\Lambda \}.
   \end{align*}
   \]

2. If \( r(\Lambda) = 21 \), then
   \[
   \begin{align*}
   \text{wt}(\Psi_\Lambda^\ell) &= (16 - r(\Lambda))(2^{g(\Lambda)} + 1)\ell - 5^3 \cdot 41\ell, \\
   \text{div}(\Psi_\Lambda^\ell) &= \ell \{ D_\Lambda^+ + (2^{g(\Lambda)} + 1) D_\Lambda^- - 2^{16 - r(\Lambda)} \{\mathcal{H}_\Lambda + (28 - r(\Lambda)) D_\Lambda^+\} \} \\
   &= 2^{-5}\ell \cdot \{ 32 D_\Lambda^- + 3 \cdot 17 \cdot 643 \cdot D_\Lambda^+ - \mathcal{H}_\Lambda \}.
   \end{align*}
   \]

**Proof.** By using \([8, \text{Th.}13.1]\), the result follows from \([8, \text{Th.}13.3]\). \(\square\)
The Petersson norm \( \| \Psi^\ell \| = \| \Psi(\cdot, \ell F_\Lambda) \| \) is an \( O(\Lambda) \)-invariant function on \( \Omega_\Lambda \). We identify \( \| \Psi^\ell \| \) with the corresponding function on \( M_\Lambda \) and set
\[
\| \Psi(\cdot, F_\Lambda) \| := \| \Psi(\cdot, \ell F_\Lambda) \|^{1/\ell}.
\]
Then \( \| \Psi(\cdot, F_\Lambda) \| \) is independent of the choice of \( \ell \in \mathbb{Z}_{>0} \) with \( 2^{r(\Lambda)-16}\ell \). If \( r(\Lambda) \leq 16 \), then \( \| \Psi(\cdot, F_\Lambda) \| \) is the ordinary Petersson norm of \( \Psi(\cdot, F_\Lambda) \).

8.2. The structure of \( \Phi_M \): the case \( \delta = 1 \). Write \( M_{g,k} \) for a primitive 2-elementary Lorentzian sublattice of \( \mathbb{L}_{K3} \) such that
\[
(g(M_{g,k}), k(M_{g,k}), \delta(M_{g,k})) = (g, k, 1).
\]
Then \( M_{g,0} \cong A_1^+ \oplus A_1^{10-g} \) and \( (r, l, \delta) = (11 - g, 11 - g, 1) \) for \( M_{g,0} \). Set
\[
\Lambda_{g,k} := M_{g,k}^+.
\]

**Lemma 8.2.** There exist mutually perpendicular roots \( d_1, \ldots, d_k \in \Delta_{\Lambda_{g,0}}^+ \) with
\[
\Lambda_{g,0} = \Lambda_{g,k} \oplus \mathbb{Z}d_1 \oplus \cdots \oplus \mathbb{Z}d_k.
\]
In particular, if \( M_{g,k} \) exists, one has \( \Omega_{\Lambda_{g,k}} = \Omega_{\Lambda_{g,k-1}} \cap H_{d_k} \).

**Proof.** The result follows from the classification in Table 1 in Proposition 1.1. \( \square \)

By Theorem 6.1 there exist integers \( a_g, b_g, c_g \in \mathbb{Z}_{\geq 0} \) for \( 3 \leq g \leq 10 \) with
\[
\text{div}(J_{M_{g,0}}^* \chi_g^k) = a_g D_{\Lambda_{g,0}}^- + b_g \mathcal{H}_{\Lambda_{g,0}} + c_g D_{\Lambda_{g,0}}^+.
\]

**Lemma 8.3.** The following inequalities and equality hold:
\[
a_g > 0, \quad b_g > 0 \quad (3 \leq g \leq 10), \quad c_g = 0 \quad (3 \leq g \leq 9).
\]

**Proof.** We get \( a_g > 0 \) by [40] Prop.
4.2 (2) and \( b_g > 0 \) by Theorem 6.1. Let \( 6 \leq g \leq 9 \). Recall that the Zariski open subset \( D_{\Lambda}^0,+ \) (resp. \( D_{\Lambda}^- \)) of \( \Delta^+ \) (resp. \( \Delta^- \)) was defined in Section 2.2. By (3.5) and Proposition 6.2 we get \( J_{M_{g,0}}(D_{\Lambda_{g,0}}^+) = J_{M_{g,0}}(\Omega_{\Lambda_{g,0}}^0) \nsubset \theta_{\text{null},g} \), which implies \( c_g = 0 \) for \( 6 \leq g \leq 9 \). Let \( 1 \leq g \leq 5 \). By [40] Prop.
4.2 (1) \( J_{M_{g,0}}(\Omega_{\Lambda_{g,0}}^0) \nsubset \theta_{\text{null},g} \). Since \( J_{M_{g,0-1}}(D_{\Lambda_{g,0-1}}^+) = J_{M_{g,0}}(\Omega_{\Lambda_{g,0}}^0) \) by (3.5) and Lemma 8.2 we get \( J_{M_{g,0-1}}(\Omega_{\Lambda_{g,0}}^0) \nsubset \theta_{\text{null},g} \) because \( D_{\Lambda_{g,0-1}}^+ \subset \Omega_{\Lambda_{g,0-1}}^0 \). By (3.5) and Lemma 8.2 again, we get \( J_{M_{g,0-2}}(\Omega_{\Lambda_{g,0}}^0) = J_{M_{g,0-1}}(\Omega_{\Lambda_{g,0-1}}^0) \nsubset \theta_{\text{null},g} \). In the same way, we get inductively \( J_{M_{g,k}}(D_{\Lambda_{g,k}}^+) \nsubset \theta_{\text{null},g} \) for \( k \leq g - 1 \). This proves \( c_g = 0 \) for \( 3 \leq g \leq 5 \). \( \square \)

**Proposition 8.4.** If \( 3 \leq g \leq 10 \), the following equality of divisors on \( \Omega_{\Lambda_{g,k}} \) holds:
\[
\text{div}(J_{M_{g,k}}^* \chi_{g,k}^s) = a_{g,k} D_{\Lambda_{g,k}}^- + 2^{\ell} b_{g,k} \mathcal{H}_{\Lambda_{g,k}} + c_{g,k} D_{\Lambda_{g,k}}^+.
\]

**Proof.** When \( g = 10 \), \( M_{g,k} \) makes sense only for \( k = 0 \) by Proposition 1.1. Hence the assertion is obvious by (8.2) when \( g = 10 \). We must prove (8.3) when \( g \leq 9 \). We shall prove by induction the existence of integers \( a_{g,k}, b_{g,k} \in \mathbb{Z} \) with
\[
\text{div}(J_{M_{g,k}}^* \chi_{g,k}^s) = a_{g,k} D_{\Lambda_{g,k}}^- + b_{g,k} \mathcal{H}_{\Lambda_{g,k}}.
\]

When \( k = 0 \), the assertion follows from (8.2) and Lemma 8.3. We assume (8.4) for \( M_{g,k} \). By Lemma 8.2 there exists \( d \in \Delta_{\Lambda_{g,k}}^+ \) such that \( \Lambda_{g,k} = \Lambda_{g,k+1} \oplus \mathbb{Z}d \).
Then $\Omega_{g,k+1} = H_d \cap \Omega_{g,k}$. Let $i : \Omega_{g,k+1} = H_d \cap \Omega_{g,k} \hookrightarrow \Omega_{g,k}$ be the inclusion. By the compatibility of Torelli maps (3.5), we get the equality of holomorphic maps

$$J_{M,g,k} \big|_{\Omega_{g,k+1} \cup D^{\infty}_{\lambda_{g,k}}} = J_{M,g,k} \circ i|_{\Omega_{g,k+1} \cup D^{\infty}_{\lambda_{g,k}}}.$$  

Hence we get the equality of holomorphic sections on $\Omega_{g,k+1} \cup D^{\infty}_{\lambda_{g,k}}$

$$(8.5) \quad J_{M,g,k}^* \chi_{g}^{\infty} = J_{M,g,k}^* \chi_{g}.$$  

Since $\Omega_{g,k+1} \setminus (\Omega_{g,k}^0 \cup D^{\infty}_{\lambda_{g,k}})$ has codimension $\geq 2$ in $\Omega_{g,k+1}$, we deduce from (8.4) and (8.7) the equation of divisors on $\Omega_{g,k+1}$

$$(8.6) \quad J_{M,g,k+1}^* \chi_{g}^{\infty} = (J_{M,g,k} \circ i)^* \chi_{g}^{\infty} = i^* J_{M,g,k}^* \chi_{g}.$$  

Comparing (8.2) with (8.12), we get

$$\text{div}(J_{M,g,k+1}^* \chi_{g}^{\infty}) = \text{div}(i^* J_{M,g,k}^* \chi_{g}^{\infty}) = i^* (a_{g,k} D_{\lambda_{g,k}} + b_{g,k} H_{\lambda_{g,k}})$$

Here the last equality follows from Propositions 2.1 and 2.2. This proves (8.4) for $M_{g,k+1}$. By induction, (8.4) holds for all $M_{g,k}$.

Since $a_{g,k+1} = a_{g,k}$ and $b_{g,k+1} = 2b_{g,k}$ for $k \geq 0$ by (8.4), (8.7), we get

$$(8.8) \quad a_{g,k} = a_{g}, \quad b_{g,k} = 2^k b_{g}$$

for $g \leq 9$ and $k \geq 0$. This proves the result. \hfill \Box

**Proposition 8.5.** If $3 \leq g \leq 10$, then the following inequalities hold:

$$a_{g} \geq 2^{2g-1}, \quad b_{g} \geq 2^4.$$  

**Proof.** The inequality $a_{g} \geq 2^{2g-1}$ follows from [40] Prop. 4.2 (2). (To confirm $J_{M}(\Omega_{g}^{0}) \not\subseteq \theta_{\text{null},g}$, it is assumed either $r > 10$ or $(r, \delta) = (10, 1)$ there. Since the same proof of [40] Prop. 4.2 (2) works under the same assumption $J_{M}(\Omega_{g}^{0}) \not\subseteq \theta_{\text{null},g}$ and since $J_{M,o}(\Omega_{g}^{0}) \not\subseteq \theta_{\text{null},g}$ for $3 \leq g \leq 10$ by Theorem 6.1 the same conclusion as in [40] Prop. 4.2 (2) still holds for $M_{g,0}$.) Let us prove the second inequality.

Let $j : \mathcal{M}_{g} \subseteq C \to \text{Jac}(C) \in A_g$ be the Torelli map. By [30] Prop. 3.1 or [32] p.542 Proof of Th. 1, we get the equality of divisors on $\mathcal{M}_{g}$

$$(8.9) \quad \text{div}(j^* \chi_{g})|_{\mathcal{M}_{g}} = 2 \mathfrak{M}_{g}.$$  

Set $\Lambda := \Lambda_{g,0}$ and $\mu_{\Lambda}^{0} := \pi_{\Lambda} \circ H_{\Lambda}|_{\Omega_{\Lambda}^{0}}$, where $H_{\Lambda} : \Omega_{\Lambda} \to \mathcal{M}_{\Lambda}$ is the projection. Since $J_{M,o}|_{\Omega_{\Lambda}^{0}} = j \circ \mu_{\Lambda}^{0}$, we get by (8.9) the following equality of divisors on $\Omega_{\Lambda}^{0}$

$$(8.10) \quad \text{div}(J_{M,o}^* \chi_{g}^{\infty})|_{\Omega_{\Lambda}^{0}} = (\mu_{\Lambda}^{0})^* \text{div}(j^* \chi_{g}^{\infty})|_{\mathcal{M}_{g}} = 2^4 (\mu_{\Lambda}^{0})^* \mathfrak{M}_{g}.$$  

Since $\text{Supp}(\mu_{\Lambda}^{0} \mathfrak{M}_{g}) \subseteq H_{\Lambda} \cap \Omega_{\Lambda}^{0}$ and since $\pi_{\Lambda}$ is irreducible by Theorem 6.1 there exists $\beta_{g} \in \mathbb{Z}_{>0}$ such that the following equality of divisors on $\Omega_{\Lambda}^{0}$ holds

$$(8.11) \quad (\mu_{\Lambda}^{0})^* \mathfrak{M}_{g} = \beta_{g} \cdot H_{\Lambda}|_{\Omega_{\Lambda}^{0}}.$$  

By (8.10), (8.11), we get the equality of divisors on $\Omega_{\Lambda}^{0}$

$$(8.12) \quad \text{div}(J_{M,o}^* \chi_{g}^{\infty})|_{\Omega_{\Lambda}^{0}} = 2^4 \beta_{g} \cdot H_{\Lambda}|_{\Omega_{\Lambda}^{0}}.$$  

Comparing (8.2) with (8.12), we get $b_{g} = 2^4 \beta_{g} \geq 2^4$. This completes the proof. \hfill \Box

**Theorem 8.6.** There exists a constant $C_{g,k,\ell}$ depending only on $g$, $k$, $\ell$ such that the following equality of automorphic forms on $\Lambda_{g,k}$ holds:

$$\Phi_{M,g,k}^{2^{g-1}(2^k+1)} = C_{g,k,\ell} \psi_{\Lambda_{g,k}}^{2^{g-1} \ell} \otimes J_{M,g,k}^* \chi_{g}.$$
In particular, there exists a constant \( C_{g,k} \) depending only on \( g, k \) such that
\[
\tau_{M_{g,k}}^{-2g(2g+1)} = C_{g,k} \| \Psi_{A_{g,k}}(\cdot, 2g-1F_{A_{g,k}}) \| \cdot J_{M_{g,k}}^* \| \chi_g^8 \| .
\]

**Proof.** Since the result was proved in [10] Th.9.1 in the case \( g \leq 2 \), we assume \( g \geq 3 \) in what follows. Set \( M := M_{g,k} \) and \( \Lambda := \Lambda_{g,k} \). Then \( r(\Lambda) \geq 5 \) and hence \( \mathcal{M}_\Lambda \setminus \mathcal{M}_\Lambda^* \) has codimension \( \geq 2 \) in \( \mathcal{M}_\Lambda^* \). By definition, \( M = M_{g,k} \) has invariants \( r(M) = 11+k-g, l(M) = 11-k-g \), so that \( r(\Lambda) = 11-k+g \) and \( l(\Lambda) = 11-k-g \).

Since \( \text{wt}(\chi_g) = 2g-2(2g+1) \) and \( \text{wt}(\Psi_\Lambda^2) = (16-r(\Lambda))\{2g+1\}^\ell \) by Theorem 8.1 we get
\[
\text{wt}(\Psi_\Lambda^{2g-1} \otimes J_M^* \chi_g^{8\ell}) = 2g-1(2g+1)\ell \cdot (16-r(\Lambda)), 4).
\]
Since \( \text{wt}(\Phi_\Lambda) = \ell (16-r(\Lambda), 4) \) by Theorem 8.1 we get by (8.13)
\[
\text{wt}(\Psi_\Lambda^{2g-1} \otimes J_M^* \chi_g^{8\ell} / \Phi_\Lambda^{2g-1(2g+1)}) = (0, 0).
\]
By (8.14),
\[
\varphi_\Lambda := (\Psi_\Lambda^{2g-1} \otimes J_M^* \chi_g^{8\ell} / \Phi_\Lambda^{2g-1(2g+1)}).
\]
descends to a meromorphic function on \( \mathcal{M}_\Lambda \). Since \( \mathcal{M}_\Lambda^* \) is normal and since \( \dim \mathcal{M}_\Lambda \setminus \mathcal{M}_\Lambda^* \leq \dim \mathcal{M}_\Lambda^* - 2 \), \( \varphi_\Lambda \) extends to a meromorphic function on \( \mathcal{M}_\Lambda^* \).

(1) Let \( r(M) \geq 2 \). Hence \( r(\Lambda) \leq 20 \). By Theorem 8.1 and Proposition 8.4 (8.15)
\[
\text{div}(\Psi_\Lambda^{2g-1} \otimes J_M^* \chi_g^{8\ell}) = 2g-1\{D_\Lambda + (2g+1)D_\Lambda^+ - 2^{16-r(\Lambda)}\mathcal{H}_\Lambda\} + a_g D_\Lambda + 2kb_g \mathcal{H}_\Lambda
\]
\[
= (2g-1 + a_g)D_\Lambda + 2g-1(2g+1)D_\Lambda^+ + 2k(b_g - 4^4)\mathcal{H}_\Lambda.
\]
Since \( \text{div}(\Phi_\Lambda) = \ell D_\Lambda \), we deduce from (8.15) that
\[
\text{div}(\varphi_\Lambda) = (a_g - 2^{2g-1})\ell D_\Lambda^+ + 2k(b_g - 4^4)\ell \mathcal{H}_\Lambda.
\]
Since \( a_g \geq 2^{2g-1} \) and \( b_g \geq 4^4 \) by Proposition 8.5, the divisor of \( \varphi_\Lambda \) is effective by (8.16). Since \( \varphi_\Lambda \) is a holomorphic function on \( \mathcal{M}_\Lambda^* \), \( \varphi_\Lambda \) must be a constant function on \( \mathcal{M}_\Lambda^* \), which implies that
\[
a_g = 2^{2g-1}, \quad b_g = 4^4.
\]
This completes the proof when \( r(M) \geq 2 \).

(2) Assume \( r(M) = 1 \). Then \( M = \mathcal{A}_T \) and \( r(\Lambda) = 21, g = 10, k = 0, \delta = 1 \). By Theorem 8.1 (2), Proposition 8.4 and the equality \( (g - 1) + 16 - r(\Lambda) = 4 \), we get (8.18)
\[
\text{div}(\Psi_\Lambda^{2g-1} \otimes J_M^* \chi_g^{8\ell})
\]
\[
= 2g-1\ell\{D_\Lambda + (2g+1)D_\Lambda^+ - 2^{16-r(\Lambda)}\mathcal{H}_\Lambda - 2^{16-r(\Lambda)}(28 - r(\Lambda))D_\Lambda^+\}
\]
\[
+ \ell \{a_g D_\Lambda + b_g \mathcal{H}_\Lambda + c_g D_\Lambda^+\}
\]
\[
= \ell\{(2g-1 + a_g)D_\Lambda + (b_g - 4^4)\mathcal{H}_\Lambda\} + \ell\{(2^{2g-1} + 2g-1 + c_g) + 4^4 \cdot 7\}D_\Lambda^+.
\]
Since \( \text{div}(\Phi_\Lambda) = \ell D_\Lambda \), we get by (8.18)
\[
\text{div}(\varphi_\Lambda) = \ell \{(a_g - 2^{2g-1})D_\Lambda + (b_g - 4^4)\mathcal{H}_\Lambda\} + \ell(c_g - 4^4 \cdot 7)D_\Lambda^+.
\]
Since \( a_g \geq 2^{2g-1} \) and \( b_g \geq 4^4 \) by Proposition 8.5, it follows from (8.19) that \( \varphi_\Lambda \) is a non-zero holomorphic function on \( \mathcal{M}_\Lambda \setminus \mathcal{A}_T \). By Lemma 8.7 below, \( \varphi_\Lambda \) is a non-zero constant. This completes the proof of Theorem 8.6. □

**Lemma 8.7.** When \( M \simeq \kappa^*_T \), any holomorphic function on \( \mathcal{M}_\Lambda \setminus \mathcal{A}_T \) is a constant.
Proof. Let \( U \subset |\mathcal{O}_{\mathbb{P}^2}(6)| \) be the space of smooth plane sextics, and let \( V \subset |\mathcal{O}_{\mathbb{P}^2}(6)| \) be that of sextics with at most one node. By the stability criterion for plane sextics \([34]\), we have a geometric quotient \( V / \mathbb{P}G_3 \) to a smooth plane sextic the double covers of \( \mathbb{P}^2 \) branched over it. Shah \([34]\) has shown that this isomorphism extends to an open embedding \( V / \mathrm{PGL}_3 \rightarrow \mathcal{M}_\Lambda \) and that its image is contained in \( \mathcal{M}_\Lambda \setminus \mathcal{D}_\Lambda \). Hence a holomorphic function on \( \mathcal{M}_\Lambda \setminus \mathcal{D}_\Lambda \) gives that on \( V / \mathrm{PGL}_3 \), which in turn is pulled-back to \( V \). Since the complement of \( V \) in \( |\mathcal{O}_{\mathbb{P}^2}(6)| \) is of codimension 2 in \( |\mathcal{O}_{\mathbb{P}^2}(6)| \), a holomorphic function on \( V \) extends to \( |\mathcal{O}_{\mathbb{P}^2}(6)| \) holomorphically and so is a constant. □

Remark 8.8. Let \((g, k) = (10, 0)\). Since \( \varphi_\Lambda \) is constant when \( \Lambda = (\mathbb{A}^+_1)^+ \), we get

\[
a_{10} = 2^{3g-1} = 2^{19}, \quad b_{10} = 2^4, \quad c_{10} = 2^4 \cdot 7
\]

by \((8.19)\). In particular, \( J_{\mathbb{A}^+_1}^* \chi_{10} \) vanishes on \( \mathcal{D}_\Lambda^+ \). Since \( U = [\mathbb{A}^+_1 \oplus Zd] \) for any \( d \in \Delta_\Lambda^+ \), this, together with \((8.35)\), implies that \( J_{\mathbb{A}^+_1}^* \chi_{10} \) vanishes identically on \( \Omega_{U^+} \).

9. The structure of \( \tau_M^1 \): the case \( \delta = 0 \)

In Section \( \mathcal{E} \) \( M \subset L_{K/3} \) is assumed to be a primitive 2-elementary Lorentzian sublattice with \( \delta = 0 \). As before, we set \( \Lambda = M^\perp \).

9.1. The structure of \( \Phi_M^1 \): the case \( r \neq 2, 10 \) and \( \delta = 0 \)

Lemma 9.1. Let \( \Lambda \cong U \oplus U(k) \oplus D_4 \oplus E_8 \) with \( k = 1, 2 \). Then the following equality of divisors on \( \Omega_\Lambda \)

\[
\text{div}(J_M^* \chi_g^8) = 2^{g-1}(2^g + 1) \mathcal{D}_\Lambda.
\]

Proof. Recall that the lattice \( \Lambda_{g, k} \) was defined in Section \( \mathcal{E} \). Since \( \Lambda_{g, k-1} \cong \Lambda \oplus \mathbb{A}_1 \) by comparing the invariants \((r, l, \delta)\), there is a root \( d \in \Delta_{\Lambda_{g, k-1}}^+ \) with \( \Lambda_{g, k-1} \cap d^\perp \cong \Lambda \). Since \( d \in \Delta_{\Lambda_{g, k-1}}^+ \), we get by \((8.3), (8.8), (8.17)\) and Propositions \(2.1\) and \(2.2\)

\[
\text{div}(J_M^* \chi_g^8) = \text{div}(J_M^* \chi_{g,k-1}^8)|_{\Omega_\Lambda} = \left\{ 2^{g-1} \mathcal{D}_{\Lambda_{g, k-1}}^+ + 2^{k+3} \mathcal{H}_{\Lambda_{g, k-1}} \right\}|_{\Omega_\Lambda}
\]

\[= 2^{g-1} \mathcal{D}_\Lambda^+ + 2^{k+4} \mathcal{H}_\Lambda = 2^{g-1}(2^g + 1) \mathcal{D}_\Lambda.
\]

To get the last equality, we used \( g - 1 = k + 4, \mathcal{D}_\Lambda^+ = 0 \) and \( \mathcal{H}_\Lambda = \mathcal{D}_\Lambda \) for \( \Lambda \), where the last two equalities follow from \( \varepsilon_\Lambda = -2, \delta(\Lambda) = 0 \) and \( 1_\Lambda = 0 \). □

Theorem 9.2. If \( r \neq 2, 10 \) and \( \delta = 0 \), there is a constant \( C_M, \ell > 0 \) depending only on \( M \) and \( \ell \) such that the following equality of automorphic forms on \( \Omega_\Lambda \)

\[
\Phi_M^{2^{g-1}(2^g + 1)} = C_M, \ell \Psi_\Lambda^{2^{g-1} \ell} \otimes J_M^* \chi_g^{8 \ell}.
\]

In particular, there is a constant \( C_M > 0 \) depending only on \( M \) such that the following equality of automorphic forms on \( \Omega_\Lambda \)

\[
\tau_M^{-2^{g}(2^g + 1)} = C_M \left\| \Psi_\Lambda \cdot 2^{g-1} F_\Lambda \right\| \cdot J_M^* \chi_g^8.
\]

Proof. When \( r > 10 \), the result was proved in \([40]\) Th. 9.1. We may assume \( 2 < r < 10 \) and \( \delta = 0 \). By Proposition \(1.1.1\) we get \( r = 6 \) and \( \Lambda \cong U \oplus U(k) \oplus D_4 \oplus E_8, k = 1, 2 \). Since \( \delta(\Lambda) = 0 \), we have \( \mathcal{D}_\Lambda^+ = 0 \) and \( 1_\Lambda = 0 \). Since \( r(\Lambda) = 16 \), we have
The structure of Prop. 9.3), Theorem 8.6 does not hold in this case. Identify \( \varphi = \phi \).

Set \( \varphi_A := \Phi^{2g-1}_A \otimes J^*_M \chi_g / \Phi^* \). Since \( \Psi_A \) is a non-zero constant, we deduce from Lemmas \[9.1\] and wt(\( \Phi_M \)) = (4\( \ell \), 4\( \ell \)), div(\( \Phi_M \)) = \( \ell \) \( \mathcal{D}_A \) that

\[
\text{(9.1)} \quad \text{wt}(\varphi_A) = (0, 0), \quad \text{div}(\varphi_A) = 0.
\]

Hence \( \varphi_A \) is a holomorphic function on \( \mathcal{M}_A \) by \[9.1\] and extends holomorphically to \( \mathcal{M}_A \). Thus \( \varphi_A \) is a non-zero constant.

\[\square\]

9.2. The structure of \( \Phi_M \): the case \((r, \delta) = (10, 0)\).

In this subsection, we assume that \( M \) is non-exceptional and \((r, \delta) = (10, 0)\).

Then \( 0 \leq l \leq 8 \) and \( 2 \leq g \leq 6 \). Since \( J^*_M \chi_g \) vanishes identically on \( \Omega (e.g. [40], Prop. 9.3) \), Theorem [8.6 does not hold in this case. Identify \( \mathcal{M}_g \) with its image by the Torelli map \( j : \mathcal{M}_g \to \mathcal{A}_g \). Then \( J_M : \Omega^0_A \to \mathcal{A}_g \) is identified with the map \( \mu_A = j^{-1} \circ J_M : \Omega^0_A \to \mathcal{M}_g \). Write \( \mathcal{S}_{\mathcal{M}, \mathcal{M}_g, \mathcal{M}_g} \subset \mathcal{M}_g \) for the hyperelliptic locus.

**Proposition 9.3.** Let \( M \) be non-exceptional with \((r, \delta) = (10, 0)\). Then \( J^*_M \chi_g \) does not vanish identically on \( \Omega^0_A \). Moreover, for any \( d \in \Delta_A, J^*[M, \mathcal{A}_g] = 0 \) is nowhere vanishing on \( \Omega^0_A \).

**Proof.** For the first assertion, it suffices to prove \( \mu_A(\Omega^0_A) \not\subset \text{div}(\chi_g) \cap \mathcal{M}_g \). Since \( \chi_g \) is nowhere vanishing on the diagonal locus of \( \mathcal{S}_2 \) and since \( \mu_A(\Omega^0_A) \) is the image of the diagonal locus by the projection \( \mathcal{S}_2 \to \mathcal{A}_2 \), we get \( \text{div}(\chi_g) \cap \mu_A(\Omega^0_A) = 0 \). Similarly, we have \( \text{div}(\chi_3) \cap \mu_A(\Omega^0_A) = 0 \) by Lemma [11]. Let \( g = 4 \). Since \( \mu_A(\Omega^0_A) \subset \text{div}(\chi) \), the inclusion \( \mu_A(\Omega^0_A) \subset \text{div}(\chi_3) \cap \mathcal{M}_g \) would imply \( \mu_A(\Omega^0_A) \subset \text{div}(\chi_3) \cap \text{div}(\chi_4) \cap \mathcal{M}_g \). Since the right hand side coincides with \( \mathcal{S}_{\mathcal{M}, \mathcal{M}_g, \mathcal{M}_g} \) by [20], p. 544 Cor., this last inclusion contradicts Lemma [7.3]. Thus \( \mu_A(\Omega^0_A) \not\subset \text{div}(\chi_4) \cap \mathcal{M}_g \). Let \( g = 5 \). Let \( F_5 \) be the Schottky form in genus 5 (cf. [17], p. 1018), whose zero divisor characterizes the (closure of) trigonal locus of \( \mathcal{M}_5 \) (cf. [17], Cor. 18). By [21], a general point of \( \mu_A(\Omega^0_A) \) is contained in the intersection of the thenthannull divisor and the trigonal locus. Then the inclusion \( \mu_A(\Omega^0_A) \subset \text{div}(\chi_3) \cap \mathcal{M}_g \) would imply

\[
\mu_A(\Omega^0_A) \subset \text{div}(F_5) \cap \text{div}(\chi_3) \cap \text{div}(\chi_4) \cap \mathcal{M}_g.
\]

Since the right hand side coincides with \( \mathcal{S}_{\mathcal{M}, \mathcal{M}_g, \mathcal{M}_g} \) by [15], p. 67, this last inclusion contradicts Lemma [7.3]. Thus \( \mu_A(\Omega^0_A) \not\subset \text{div}(\chi_5) \cap \mathcal{M}_g \). When \( g = 6 \), we get \( \mu_A(\Omega^0_A) \not\subset \text{div}(\chi_6) \cap \mathcal{M}_g \) by Lemma [4.1] and Lemma [7.4]. This proves the first assertion. Since \( r(|M|, d|) > 10 \), the second assertion follows from [40], Prop. 4.2 (1)]. This completes the proof.

\[\square\]

**Theorem 9.4.** Let \( M \) be non-exceptional with \((r, \delta) = (10, 0)\). Then there is a constant \( C_{M, \ell} > 0 \) depending only on \( M \) and \( \ell \) such that the following equality of automorphic forms on \( \Omega_A \) holds

\[
\Phi^{(2g-1+1)(2g-1)}(2g-1) = C_{M, \ell} \Psi^{(2g-1+1)\ell} \otimes J^*_M \chi_g.
\]

In particular, there is a constant \( C_M > 0 \) depending only on \( M \) such that

\[
\tau^{(2g+1)(2g-1)} = C_M \left\| \Psi(\cdot, (2g-1 + 1) F_3) \right\| \cdot J^*_M \chi_g.
\]
Proof. Since \((r, \delta) = (10, 0)\), we get \((r(\Lambda), \delta(\Lambda)) = (12, 0)\). By [40, Th. 8.1],
\[
(9.2) \quad \text{wt}(\Psi_\Lambda) = (4(2^g - 1), 0), \quad \text{div}(\Psi_\Lambda) = \mathcal{D}_\Lambda.
\]
Since \(J_M^* \Upsilon_g\) does not vanish identically on \(\Omega^0_\Lambda\) by Proposition [9.3] and since \(\mathcal{D}_\Lambda\) is irreducible, there exists \(a \in \mathbb{Z}_{\geq 0}\) and an effective divisor \(\mathcal{E}_\Lambda\) on \(\Omega_\Lambda\) such that
\[
(9.3) \quad \text{wt}(J_M^* \Upsilon_g) = (0, 4(2^g - 1)(2^g - 1)), \quad \text{div}(J_M^* \Upsilon_g) = a \mathcal{D}_\Lambda + \mathcal{E}_\Lambda.
\]
Set \(\Phi := \Psi_A^{(2^g-1)+1} \otimes J_M^* \Upsilon_g / \Phi_M^{(2^g-1)(2^g-1)}\). Comparing (9.2), (9.3) and \(\text{wt}(\Phi_M) = (4\ell, 4\ell), \text{div}(\Phi_M) = \ell \mathcal{D}_\Lambda, \ell \mathcal{E}_\Lambda\), we get
\[
(9.4) \quad \text{wt}(\varphi_\Lambda) = (0, 0), \quad \text{div}(\varphi_\Lambda) = \ell \{a - 2(2^{2g-1} - 1)\} \mathcal{D}_\Lambda + \ell \mathcal{E}_\Lambda.
\]
By Proposition [9.3], we can apply Lemma [43] to a general curve \(\gamma: \Delta \to \mathcal{M}_\Lambda\) intersecting \(\mathcal{D}_\Lambda\) transversally. Since \(a \geq 2(2^{2g-1} - 1)\) by Lemma [43] we get \(\text{div}(\varphi_\Lambda) \geq 0\). By the Koecher principle, \(\varphi_\Lambda\) is a non-zero constant. \(\square\)

In the rest of this section, we determine \(\Phi_M\) for the remaining \(M\), i.e., those \(M\) with \((r, \delta) = (2, 0)\). Then, either \(M \cong \mathbb{U}\) or \(\mathbb{U}(2)\).

9.3. The structure of \(\Phi_\Omega\). In Section [9.3] we set
\[
M := \mathbb{U}, \quad \Lambda = M^\perp := \mathbb{U}^\oplus \oplus \mathbb{E}^\oplus 2.
\]
Then \(q = 10\) and \(J_M^* \chi_{10}\) vanishes identically on \(\Omega^0_\Lambda\).

Let \(E_4(\tau) = \theta_{\mathbb{E}^\perp}(\tau) = 1 + 240q + \cdots\) be the Eisenstein series of weight 4 (or equivalently the theta series of \(\mathbb{E}^\perp\)) and set
\[
(9.5) \quad f_\Lambda(\tau) := E_4(\tau) / \eta(\tau)^{24} = q^{-1} + 264 + O(q).
\]
Then \(f_\Lambda(\tau)\) is a modular form of weight \(-8\). In Section [5.3] we prove the following:

Theorem 9.5. There exists a constant \(C_{M, \ell} > 0\) such that
\[
\Phi_M^{(2^g-1)(2^g-1)} = C_{M, \ell} \Psi_A(\cdot, 2^{g-1}F_\Lambda + f_\Lambda)^\ell \otimes J_M^* \Upsilon_g.
\]
In particular, there is a constant \(C_M > 0\) depending only on \(M = \mathbb{U}\) such that
\[
\mathcal{M}_M^{-(2^g-1)(2^g+2)} = C_M \| \Psi_A(\cdot, 2^{g-1}F_\Lambda + f_\Lambda) \| \cdot J_M^* \| \Upsilon_g \|.
\]

For the proof of Theorem 9.5 we first prove the following:

Lemma 9.6. \(J_M^* \Upsilon_{10}\) is nowhere vanishing on \(\Omega^0_\Lambda \setminus H_\Lambda\).

Proof. Let \((X, \iota, \alpha)\) be an arbitrary marked 2-elementary K3 surface of type \(M = \mathbb{U}\) with period in \(\Omega_\Lambda \setminus H_\Lambda\). Let \(C\) be the component of genus 10 of \(X^e\). Fix a symplectic basis of \(H_1(C, \mathbb{Z})\), so that \(\Omega(C) \in \mathcal{G}_{10}\), where \(\Omega(C)\) is the period of \(C\) with respect to the symplectic basis. By Proposition [9.1] there is a unique even pair \((a_0, b_0)\), \(a_0, b_0 \in \{0, 1\}^{10}\) such that \(\theta_{a_0, b_0}(\Omega(C)) = 0\) and \(\theta_{a, b}(\Omega(C)) \neq 0\) for all even pair \((a, b)\) with \((a, b) \neq (a_0, b_0)\). Hence we get
\[
J_M^* \Upsilon_{10}(X, \iota) = \Upsilon_{10}(\Omega(C)) = \prod_{(a, b) \neq (a_0, b_0)} \theta_{a, b}(\Omega(C))^{8} \neq 0.
\]
This proves the lemma. \(\square\)
By Lemma 9.6, there exist \( \alpha, \beta \in \mathbb{Z}_{>0} \) such that
\[
(9.6) \quad \ override(9.6) \quad \text{div}(J^*_{\mathcal{M}} \mathcal{T}_{10}) = \alpha D_{\Lambda} + \beta \mathcal{H}_{\Lambda}.
\]

To prove Theorem 9.3, we must determine \( \beta \). We use the following notation: Set
\[
L := \mathbb{U} \oplus \mathbb{U} \oplus \mathbb{E}_8 \oplus \mathbb{E}_8 \oplus \mathbb{A}_1 = \Lambda \oplus \mathbb{A}_1.
\]
Let \( d \in \Delta^+_L \) be a generator of \( \mathbb{A}_1 \). Then \( \Lambda = L \cap d^+ \), \( L^+ = \mathbb{A}_1^+ \) and \( A_L = \{ 0, 1_L \} \), where \( 1_L = [d/2] \). As before, we make the identification
\[
H_d = \Omega_{L\cap d^+} = \Omega_{\Lambda}.
\]

Let \([\eta]\) \in \mathcal{H}^2_d \) be an arbitrary point. Let \( U \cong \Delta^19 \) be a small neighborhood of \([\eta]\) in \( \Omega_L \) equipped with a system of coordinates \((t, s_1, \ldots, s_{18})\) such that \( U \cap \mathcal{D}_L = U \cap H_d = U \cap \Omega_{\Lambda} = \{ (t, s) : t \neq 0 \} \cong \Delta^{18} \). Since \( d \in \Delta^+_L \) and hence \( g(L) = g(\Lambda) = 10 \) by Lemma 11.5, the Torelli map \( J_{\mathcal{A}_1^+} \) is a holomorphic map from \( U \to \mathcal{A}_{10} \) by Theorem 3.5. Let \( \Pi : \mathcal{S}_{10} \to \mathcal{A}_{10} \) be the projection. Since \( U \) is contractible, \( J_{\mathcal{A}_1^+} : U \to \mathcal{A}_{10} \) is liftable. Namely, there exists a holomorphic map \( \tilde{J}_{\mathcal{A}_1^+} : U \to \mathcal{S}_{10} \) such that
\[
J_{\mathcal{A}_1^+} = \Pi \circ \tilde{J}_{\mathcal{A}_1^+}.
\]

Since \( \tilde{J}_{\mathcal{A}_1^+} \) takes its values in \( \mathcal{S}_{10} \), the value \( \theta_{a,b}(\tilde{J}_{\mathcal{A}_1^+}(t, s)) \) makes sense for all \((s, t) \in U \) and even \((a, b), (a, b) \in \{0, 1/2\}^{10} \). Since \( \tilde{J}_{\mathcal{A}_1^+} : \mathcal{S}_{10} \to \mathcal{S}_{10} \) is nowhere vanishing on \( U \setminus (\mathcal{D}_L \cup H_d) \) and since there exists by Proposition 7.1 a unique even theta constant \( \theta_{a_0, b_0} \) vanishing identically on \( H_d \), we get the following:

- \( U \cap H_d \) is a component of \( U \cap \text{div}(\tilde{J}_{\mathcal{A}_1^+} \theta_{a_0, b_0}) \);
- \( U \cap H_d \) is not a component of \( U \cap \text{div}(\tilde{J}_{\mathcal{A}_1^+} \theta_{a,b}) \) for any even \((a, b) \neq (a_0, b_0) \).

Thus there exist \( c \in \mathbb{Z}_{>0}, c_{a,b}(\lambda) \in \mathbb{Z}_{\geq 0} \) such that for \((a, b) = (a_0, b_0) \)
\[
(9.7) \quad \text{div}(\tilde{J}_{\mathcal{A}_1^+} \theta_{a_0, b_0})|_U = c H_d + \sum_{\lambda \in L^+/\pm 1, \lambda^2 = -9/2, |\langle \lambda, d \rangle| = 1} c_{a_0, b_0}(\lambda) H_{\lambda}
\]
and such that for all \((a, b) \neq (a_0, b_0) \)
\[
(9.8) \quad \text{div}(\tilde{J}_{\mathcal{A}_1^+} \theta_{a,b})|_U = \sum_{\lambda \in L^+/\pm 1, \lambda^2 = -9/2, |\langle \lambda, d \rangle| = 1} c_{a,b}(\lambda) H_{\lambda}.
\]

Let \( s_d \in \mathcal{O}(d) \) be the reflection with respect to \( d \). Since \( J_{\mathcal{A}_1^+} \circ s_d = J_{\mathcal{A}_1^+} \), we have \( s_{d}^* \circ (\tilde{J}_{\mathcal{A}_1^+})^* = (\tilde{J}_{\mathcal{A}_1^+})^* \), which implies the following equality for every even pair \((a, b) \)
\[
(9.9) \quad c_{a,b}(s_{d}(\lambda)) = c_{a,b}(\lambda).
\]

**Lemma 9.7.** Let \( \lambda \in L^+ \) be such that \( \lambda^2 = -9/2, |\langle \lambda, d \rangle| = 1, |\lambda| = 1_L \). If \( c_{a_0, b_0}(\lambda) > 0 \), then \( c_{a,b}(\lambda) = 0 \) for all \((a, b) \neq (a_0, b_0) \).

**Proof.** Assume \( c_{a_0, b_0}(\lambda) > 0 \) and \( c_{a', b'}(\lambda) > 0 \) for some even \((a', b') \neq (a_0, b_0) \). Then, for every 2-elementary \( K3 \) surface \((X, \iota)\) of type \( \mathcal{A}_1^+ \) whose period lies in \( U \cap H_1 \setminus H_d \), \( X^\iota \) has two distinct effective even half canonical bundles corresponding to \((a_0, b_0)\) and \((a', b')\). This contradicts Remark 6.10.
Recall that \( i : \Omega_\Lambda \hookrightarrow \Omega_L \) is the inclusion induced by that of lattices \( \Lambda = L \cap d^{-1} \subset L \). On \( H_d^0 \cap U \), set
\[
\tilde{J}_M := \tilde{J}_{\tilde{A}_1^+} \mid_{U \cap H_d^0}.
\]
By \eqref{9.6}, we have \( J_M = \Pi \circ \tilde{J}_M \).

Since \( U \cap H_d \subset H_d^0 = \Omega_{\Lambda}^0 \), we have the following equality of divisors on \( U \cap \Omega_{\Lambda}^0 \) by \eqref{9.6}
\[
\text{div}(\tilde{J}_M^* \Upsilon_{10}) \mid_{U \cap H_d} = \beta \sum_{\mu \in \Lambda/\pm 1, \mu^2 = -4} H_\mu.
\]

Lemma 9.8. For every \( \lambda \in L^\vee \) with \( \lambda^2 = -9/2, \langle \lambda, d \rangle = \pm 1, \lambda \equiv 1_L \mod L \), the following equalities hold \( c_{a,0,b_0}(\lambda) = 0 \), \( \sum_{(a,b) \neq (a_0,b_0)} c_{a,b}(\lambda) = \beta/2 \).

Proof. Since \( \tilde{J}_{\tilde{A}_1^+}^* (\chi_{10}/\theta_{a_0,b_0})^8 \mid_{U \cap H_d} = \tilde{J}_M^* \Upsilon_{10} \mid_{U \cap H_d} \) by the definitions of \( \Upsilon_g \) and \( \theta_{a_0,b_0} \), we get the equality of divisors on \( U \cap \Omega_{\Lambda}^0 \)
\[
i^* \text{div}(\tilde{J}_{\tilde{A}_1^+}^* (\chi_{10}/\theta_{a_0,b_0})^8 \mid_{U}) = i^* \text{div}(\tilde{J}_M^* \Upsilon_{10} \mid_{U}) = \text{div}(\tilde{J}_M^* \Upsilon_{10}),
\]
where the second equality follows from \eqref{9.10}. On the other hand, we get by \eqref{9.8}
\[
\text{div}(\tilde{J}_{\tilde{A}_1^+}^* (\chi_{10}/\theta_{a_0,b_0})^8 \mid_{U}) = \lambda \in L^\vee / \pm 1, \lambda^2 = -9/2, \langle \lambda, d \rangle = 1, [\lambda] = 1_L \langle a,b \rangle \neq (a_0,b_0)
\]
which, together with \eqref{2.2}, yields the following equality of divisors on \( U \)
\[
i^* \text{div} \left( \tilde{J}_{\tilde{A}_1^+}^* \left( \frac{\chi_{10}}{\theta_{a_0,b_0}} \right)^8 \mid_{U} \right) = \sum_{\mu \in \Lambda / \pm 1, \mu^2 = -4} \{ \sum_{(a,b) \neq (a_0,b_0)} c_{a,b}(\lambda) \} H_\mu.
\]
Substituting \eqref{9.11}, \eqref{9.13} into \eqref{9.12} and comparing the coefficients of \( H_\mu \), we get
\[
\sum_{(a,b) \neq (a_0,b_0)} \{ c_{a,b}(\mu + \frac{d}{2}) + c_{a,b}(\mu - \frac{d}{2}) \} = \beta.
\]
Since \( c_{a,b}(\mu + \frac{d}{2}) = c_{a,b}(\mu - \frac{d}{2}) \) by \eqref{9.9}, we get \( \sum_{(a,b) \neq (a_0,b_0)} c_{a,b}(\lambda) = \beta/2 \) by \eqref{9.14}. If \( c_{a_0,b_0}(\lambda) > 0 \), then \( \sum_{(a,b) \neq (a_0,b_0)} c_{a,b}(\lambda) = 0 \) by Lemma \ref{8.7} Since \( \beta > 0 \), this contradicts the equality \( \sum_{(a,b) \neq (a_0,b_0)} c_{a,b}(\lambda) = \beta/2 \). Thus \( c_{a_0,b_0}(\lambda) = 0 \). \( \square \)

Lemma 9.9. One has the equality \( \beta = 2^5 \).

Proof. By \eqref{9.7}, \eqref{9.8} and Lemma \ref{8.8}, we get on \( U \)
\[
\text{div}(\tilde{J}_{\tilde{A}_1^+}^* \theta_{a_0,b_0}^8) = c H_d, \quad \text{div}(\tilde{J}_{\tilde{A}_1^+}^* (\chi_{10}/\theta_{a_0,b_0})^8) = (\beta/2) \cdot \mathcal{H}_L,
\]
which yields the equality of divisors \( \text{div}(J_{\tilde{A}_1^+}^* \chi_{10}^8) = c D_L^+ + (\beta/2) \cdot \mathcal{H}_L \) on \( U \). By Remark \ref{8.8} we get \( c = c_{10} = 2^4 \cdot 7 \) and \( \beta/2 = b_{10} = 2^4 \). Thus \( \beta = 2^5 \). \( \square \)

Proof of Theorem 9.5 By Theorem \ref{8.1} \( 1 \), we have
\[
\text{wt}(\Psi_A^{2^l}) = -4(2^l + 1)(2^0 - 2^l + 1), \quad \text{div}(\Psi_A^{2^l}) = 2^4 D_A - \mathcal{H}_A.
\]
By \([8]\) Th. 13.3, we get
\[
\text{wt}(\Psi_A(\cdot, f_A)) = 2^2(2^5 + 1), \quad \text{div}(\Psi_A(\cdot, f_A)) = D_A.
\]
By \((9.15), (9.16)\), we get
\[
\text{wt}(\Psi_A(\cdot, 2^g F_A + \tau)) = -2^2(2^9 + 1)(2^{10} - 1),
\]
\[
\text{div}(\Psi_A(\cdot, 2^g F_A + \tau)) = (2^9 + 1)D_A - 2^{99} \mathcal{H}_A.
\]
Set \(\varphi_A := \Psi_A(\cdot, 2^g F_A + \tau) \otimes \Upsilon_g^\ell / \Phi^\ell_{M_A}(2^g - 1)\). Since \(\text{wt}(\Phi_M) = (-4\ell, 4\ell)\) and \(\text{div}(\Phi_M) = \ell D_A\), we deduce from \((9.17), (9.18)\) that \(\text{wt}(\varphi_A) = (0, 0)\) and
\[
\text{div}(\varphi_A) = \ell (\alpha - 2(2^9 - 1)) D_A + (\beta - 2^{99}) \mathcal{H}_A = \ell (\alpha - 2(2^9 - 1)) D_A,
\]
where we used Lemma 9.9 to get the second equality. By Lemma 9.6 and Theorem 8.3 for \([M \perp / d]\), \(d \in \Delta_A\), Lemma 4.3 applies to a general curve \(\gamma: \Delta \to M_A\) intersecting \(D_A\) transversally. Since \(\alpha \geq 2(2^9 - 1)\) by Lemma 4.3 we get \(\text{div}(\varphi_A) \geq 0\). As before, this implies that \(\varphi_A\) is a constant. \(\square\)

9.4. The structure of \(\Phi_{\U(2)}\). In Section 9.4, we set\[
M := \U(2), \quad A = M^\perp := \U(2) \oplus \E_8 \oplus \E_8.
\]
Then \(g = 9\) and \(J_M^\perp\) vanishes identically. Let \(\{e, f\}\) be a basis of \(\U(2)\) with \(e^2 = f^2 = 0\) and \(e, f\) \(= 2\). Hence \((e + f)/2 \in A\) is the unique element with non-zero norm. Let \(e_{00}, e_{01}, e_1, e_{11}\) be the standard basis of \(C[A]\), where \(e_{0\beta}\) corresponds to \((\alpha e + \beta f)/2 \in A\). Applying the construction \([9]\) Proof of Lemma 11.1, \([33]\) Th. 6.2 to the modular form \(\eta(\tau)^{-8}\eta(2\tau)^{-8}\), we define
\[
f_A(\tau) := 8 \sum_{\gamma \in A_d} \eta(\tau)^{-8}\eta(\tau)^{-8} + (-1)^{g(\gamma)}\eta(\tau + 1)^{-8}\eta(\tau + 1)^{-8} e_\gamma
\]
\[
+ \eta(\tau)^{-8}\eta(2\tau)^{-8} e_{00}.
\]
Then \(f_A(\tau)\) is a modular form of weight \(-8\) and of type \(\rho_A\) with principal part \(\eta(\tau) + 136 e_{00} + 16q^{-1}\) \(e_{11}\).

Since \(O(q)\) preserves \((e + f)/2\), the Heegner divisor of \(\Omega\)
\[
\mathcal{H}_A(-1, e_{11}) := \sum_{\lambda \in \Lambda / \Lambda^\ell: \lambda^2 = -1, \lambda^2 = (e + f) / 2} \mod \Lambda
\]
is \(O(\Lambda)\)-invariant. By \([8]\) Th. 13.3, the Borcherds lift \(\Psi_A(\cdot, f_A)\) is an automorphic form on \(\Omega\) for \(O(\Lambda)\) such that
\[
\text{wt } \Psi_A(\cdot, f_A) = 68 = 2^6 + 2^2, \quad \text{div } \Psi_A(\cdot, f_A) = D_A + 2^4 \mathcal{H}_A(-1, e_{11}).
\]

In this subsection, we prove the following:

**Theorem 9.10.** There exists a constant \(C_M, \ell > 0\) such that
\[
\Phi_M(2^g - 1)(2^g - 1) = C_M, \ell \Psi_A(\cdot, 2^g F_A + \tau) \otimes J_M^\ell \Upsilon_g^\ell.
\]
In particular, there is a constant \(C_M > 0\) depending only on \(M = \U(2)\) such that
\[
\tau_M(2^g + 2)(2^g - 1) = C_M \|\Psi_A(\cdot, 2^g F_A + \tau)\| \cdot \|J_M^\ell \Upsilon_g\|.
\]
Define the reduced divisor $H_1$ on $\Omega_\Lambda$ as

$$H_1 := H_\Lambda - H_\Lambda(-1, e_{11}) = \sum_{\lambda \in \Lambda, \ell_+ = -4, \ell_- = 1} H_\lambda.$$  

The divisor $\mathcal{H}_1 \subset \mathcal{M}_\Lambda$ in Section 7.2 is obtained as the quotient $\mathcal{H}_1 = H_1/O(\Lambda)$.

**Lemma 9.11.** $J_M^* \Upsilon_9$ is nowhere vanishing on $\Omega_\Lambda^0 \setminus H_1$.

**Proof.** By using Proposition 7.2 instead of Proposition 7.1, the proof is parallel to that of Lemma 9.6. \hfill \Box

By Lemma 9.11 there exist $\alpha, \beta \in \mathbb{Z}_{>0}$ such that

$$\text{(9.21)} \quad \text{div}(J_M^* \Upsilon_9) = \alpha D_\Lambda + \beta H_1.$$  

**Lemma 9.12.** One has the inequality $\beta \geq 2^4$.

**Proof.** Let $\lambda \in \Lambda$ be an arbitrary vector such that $\lambda^2 = -4$ and div($\lambda$) = 1. We set

$$H^0_\Lambda := H_\Lambda \setminus (D_\Lambda \cup \bigcup_{\lambda \in \Lambda, (\lambda')^2 = -4, \text{div}(\lambda') = 1} H_\Lambda).$$  

Then $H^0_\Lambda$ is a non-empty Zariski open subset of $H_\Lambda$. Let $[\eta] \in H^0_\Lambda$ be an arbitrary point. Let $U \cong \Delta^4$ be a small neighborhood of $[\eta]$ in $\Omega_\Lambda$ such that $U \cap (H_1 \cup D_\Lambda) = U \cap H^0_\Lambda \cong \Delta^4$. Since $U$ is small enough, there is a marked family of 2-elementary $K3$ surfaces $((x_1,t) \to U, a)$ of type $M = U(2)$, whose period map is the inclusion $U \to \Omega_\Lambda$. Set $C := \mathcal{X}'$. Then $p: C \to U$ is a family of smooth curves of genus 9. Set $C_t := p^{-1}(t) \cap C$ for $t \in U$. The period map $J_M|_U$ is a holomorphic map from $U$ to $\mathfrak{A}_9$ such that $J_M(t) = \Omega(C_t)$. Since $U$ is contractible, the local system $R^1(p|_C)^*\mathcal{Z}$ is trivial and admits a symplectic basis. Hence $J_M: U \to \mathfrak{A}_9$ lifts to a holomorphic map $\tilde{J}_M: U \to \mathfrak{S}_9$ such that $\tilde{J}_M = \Pi \circ \tilde{J}_M$, where $\Pi: \mathfrak{S}_9 \to \mathfrak{A}_9$ is the projection. Since $\tilde{J}_M$ takes its values in $\mathfrak{S}_9$, the value of the theta constant $\theta_{a,b}(\tilde{J}_M(t))$ makes sense for all $t \in U$ and for every even pair $(a,b)$, $a,b \in \{0,1/2\}^9$. Moreover, since the family $p: C \to U$ admits a level 4l-structure for any $l \in \mathbb{Z}_{>0}$, the square root $\tilde{J}_M^* \sqrt{\theta_{a,b}}$ is a well-defined holomorphic section of a holomorphic line bundle on $U$ for every even pair $(a,b)$ by [37, Th. 1]. Since any holomorphic line bundle on $U$ is trivial, we may regard $\tilde{J}_M^* \sqrt{\theta_{a,b}} \in \mathcal{O}(U)$.

We deduce from Proposition 7.2 the existence of a unique even pair $(a_0, b_0)$ and at least one even pair $(a_1, b_1)$ with the following properties:

1. $\tilde{J}_M^* \theta_{a_0,b_0}$ vanishes identically on $U$;
2. Set-theoretically, $U \cap \text{div}(\tilde{J}^*_M \theta_{a_1,b_1}) = U \cap H_\Lambda$.

By (2) and the fact $\tilde{J}_M^* \sqrt{\theta_{a_1,b_1}} \in \mathcal{O}(U)$, there exists $c \in \mathbb{Z}_{>0}$ such that on $U$

$$\text{div}(\tilde{J}^*_M \theta_{a_1,b_1}) = 2c H_\Lambda.$$  

By (1) and the definition of $\Upsilon_9$, we have

$$\tilde{J}_M^* \Upsilon_9|_U = \prod_{(a,b) \neq (a_0,b_0)} \tilde{J}_M^* \theta_{a,b} = \tilde{J}_M^* \theta_{a_0,b_0} \prod_{(a,b) \neq (a_0,b_0),(a_1,b_1)} \tilde{J}_M^* \theta_{a,b}.$$  

Setting $E := \text{div}(\prod_{(a,b) \neq (a_0,b_0),(a_1,b_1)} \tilde{J}_M^* \theta_{a,b})$, we get the equality of divisors on $U$

$$\text{div}(\tilde{J}_M^* \Upsilon_9|_U) = 16c H_\Lambda + E.$$  

Thus we get the desired inequality $\beta \geq 16c \geq 2^4$. \hfill \Box
Proof of Theorem 9.10 By Theorem 8.1 (2), we get
\[(9.22) \quad \operatorname{wt}(\Phi_{\lambda}) = -2^{-2}(2^4(2^9 + 1) + 1)\ell, \quad \operatorname{div}(\Phi_{\lambda}) = \ell (D_\Lambda - 2^{-4}H_\Lambda).\]

By (9.20) and (9.22), we get
\[
\operatorname{wt}(\Phi_{\lambda}^* \cdot \Psi_{\lambda}(\cdot, f_\lambda)) = -2^2(2^8+1)(2^9-1), \quad \operatorname{div}(\Phi_{\lambda}^* \cdot \Psi_{\lambda}(\cdot, f_\lambda)) = (2^8+1)D_\Lambda - 2^4H_1.
\]

Since \(\operatorname{wt}(J_M^* \Upsilon_9) = (0, 2^2(2^8+1)(2^9-1))\) and \(\operatorname{div}(J_M^* \Upsilon_9) = \alpha D_\Lambda + \beta H_1\) by (9.21), we get
\[
\operatorname{wt}(\Psi_{\lambda}(\cdot, 2^8F_\lambda + f_\lambda) \otimes J_M^* \Upsilon_9) = -4(2^8+1)(2^9-1), 4(2^8+1)(2^9-1),
\]
\[
\operatorname{div}(\Psi_{\lambda}(\cdot, 2^8F_\lambda + f_\lambda) \otimes J_M^* \Upsilon_9) = (\alpha + 2^8 + 1)D_\Lambda + (\beta - 2^4)H_1.
\]

Since \(\operatorname{wt}(\Phi_M) = (-4\ell, 4\ell)\) and \(\operatorname{div}(\Phi_M) = \ell D_\Lambda\),
\[
\varphi_{\lambda} := \Psi_{\lambda}(\cdot, 2^8F_\lambda + f_\lambda)^\ell \otimes J_M^* \Upsilon_9 / \Phi_{\lambda}^{(2^8+1)(2^9-1)}
\]
is a meromorphic function on \(M_\lambda\) with divisor
\[
\operatorname{div}(\varphi_{\lambda}) = \ell(\alpha - 2(2^{16} - 1))D_\Lambda + \ell(\beta - 2^4)H_1.
\]

By Lemma 9.11 and Theorem 8.6 for \([M \perp d], d \in \Delta_\Lambda\), Lemma 8.9 applies to a general curve \(\gamma : \Delta \to M_\Lambda\) intersecting \(\overline{D_\Lambda}\) transversally. Since \(\alpha \geq 2(2^{16} - 1)\) and \(\beta \geq 2^4\) by Lemmas 8.3 and 8.12 we get \(\operatorname{div}(\varphi_{\lambda}) \geq 0\). Thus \(\varphi_{\lambda}\) is a constant. \(\Box\)

9.5. The divisors of \(J_M^* \chi_8^8\) and \(J_M^* \Upsilon_9\).

Theorem 9.13. Let \(M\) be a non-exceptional primitive 2-elementary Lorentzian sublattice of \(\mathbb{L}_{K_3}\) with \(\Lambda = M^\perp\) and invariants \((r, l, \delta)\). Then the following holds:
(1) If \(g = 0\), i.e., \(r + l = 22\), then \(\operatorname{div}(J_M^* \chi_8^8) = 0\).
(2) If \(r \geq 2\), \(\delta = 1\) and \(1 \leq g \leq 9\), then \(\operatorname{div}(J_M^* \chi_8^8) = 2^{2^g - 1}D_\Lambda + 2^{k+4}H_\Lambda\).
(3) If \((r, \delta) = (1, 1)\), then \(\operatorname{div}(J_M^* \chi_8^8) = 2^9D_\Lambda + 2^4\cdot 7D_\Lambda + 2^4H_\Lambda\).
(4) If \(\delta = 0\) and \(r \neq 2, 10\), then \(\operatorname{div}(J_M^* \chi_8^8) = 2^{2^g - 1}(2^g + 1)D_\Lambda\).
(5) If \((r, \delta) = (2, 0)\) or \((10, 0)\), then \(J_M^* \chi_8^8\) vanishes identically on \(\Omega_\Lambda\).
(6) If \((r, \delta) = (10, 0)\), then \(\operatorname{div}(J_M^* \Upsilon_9) = 2(2^{2^g-1} - 1)D_\Lambda\).
(7) If \((r, l, \delta) = (2, 0, 0)\), then \(\operatorname{div}(J_M^* \Upsilon_{10}) = 2(2^{18} - 1)D_\Lambda + 2^5H_\Lambda\).
(8) If \((r, l, \delta) = (2, 2, 0)\), then \(\operatorname{div}(J_M^* \Upsilon_9) = 2(2^{16} - 1)D_\Lambda + 2^4\{H_\Lambda - H_\Lambda(-1, e_{11})\}\).

Proof. The assertion (1) is obvious since \(\chi_8 = 1\) for \(g = 0\). For \(g = 1, 2\) (resp. \(3 \leq g \leq 9\)), we get (2) by [40] Proposition 4.2 (2), (3) (resp. Lemma 8.3 Proposition 8.4 (8.17)). We get (3) by Proposition 8.3 (8.17), 8.20. When \(r > 10\) (resp. \(2 < r < 10\)), we get (4) by [40] Equ. (9.3) and the equality \(a = E = 0\) in [40] Proof of Th. 9.1] (resp. Lemma 9.11). We get (5) by [40] Proposition 9.3 when \(r = 10\). When \(r = 2, \delta = 0\), there are two possible cases: \(g = 10\) and \(g = 9\). In case \(g = 10\), (5) was proved in Remark 8.5. In case \(g = 9\), (5) was proved in Section 7.2. This proves (5). We get (6) by [9.3] and the equality \(a = 2(2^{2^g-1} - 1)\) in the proof of Theorem 9.4. We get (7) by [9.6], since \(\beta = 2^5\) and \(\alpha = 2(2^{18} - 1)\) in the proof of Theorem 9.5. We get (8) by [9.21], since the equalities \(\alpha = 2(2^{16} - 1)\) and \(\beta = 2^4\) follow from the proof of Theorem 9.10. This completes the proof. \(\Box\)

Corollary 9.14. For \((r, l, \delta) = (10, 2, 0), (10, 4, 0), J_M(\Omega_{11})\) is disjoint from the hyperelliptic locus. For \((r, l, \delta) = (10, 0, 0)\), every member of \(J_M(\Omega_{11})\) has exactly one effective even theta characteristic.
Proof. Set-theoretically, \( \delta_{hyp,4} \) (resp. \( \delta_{hyp,5} \)) is given by \( \text{div}(\chi_4) \cap \text{div}(\Upsilon_4) \) (resp. \( \text{div}(\chi_5) \cap \text{div}(\Upsilon_5) \cap \text{div}(F_5) \)) on \( \mathbb{M}_4 \) (resp. \( \mathbb{M}_5 \)). Since \( J^*_M \Upsilon_4 \) (resp. \( J^*_M \Upsilon_5 \)) is nowhere vanishing on \( \Omega^1_4 \) by Theorem \ref{thm:main} (6) for \((r, l, \delta) = (10, 4, 0) \) (resp. \((10, 2, 0) \)), we get the first assertion. When \((r, l, \delta) = (10, 0, 0) \), \( J^*_M \Upsilon_6 \) vanishes identically on \( \Omega^1_6 \) and \( J^*_M \Upsilon_6 \) is nowhere vanishing on \( \Omega^1_4 \) by Theorem \ref{thm:main} (5), (6). This, together with Lemma \ref{lem:spin1}, implies the second assertion. \( \square \)

Let us give a geometric interpretation of Theorem \ref{thm:main}, where we use the notion of log Del Pezzo surfaces of index \( \leq 2 \). We refer to \cite{1} for this notion. Let \( S \) be a log Del Pezzo surface of index \( \leq 2 \). By \cite{1} Th. 1.5, the bi-anticanonical system of \( S \) contains a smooth member. For any smooth member \( C \in | - 2K_S | \), one can canonically associate a 2-elementary K3 surface \((X_{(S,C)}, \iota_{(S,C)}) \) whose quotient \( X_{(S,C)}/\iota_{(S,C)} \) is the right resolution of \( S \). (See \cite{1} Sect. 2.1) We define the invariant \( \delta(S) \in \{0, 1\} \) as that of the 2-elementary lattice \( H^2(X_{(S,C)}, \mathbb{Z})_+ \). Then \( \delta(S) \) is independent of the choice of a smooth member \( C \in | - 2K_S | \).

**Corollary 9.15.** Let \( S \) be a log Del Pezzo surface of index \( \leq 2 \) and let \( C \in | - 2K_S | \) be a smooth member. If \( S \not\equiv F_0, P(1, 1, 2) \), then the following hold:

1. When \( (\rho(S), \delta(S)) \neq (2, 0), (10, 0) \), \( C \) has an effective even theta characteristic if and only if the period of \((X_{(S,C)}, \iota_{(S,C)}) \) lies in the characteristic Heegner divisor.

2. When \( (\rho(S), \delta(S)) = (2, 0) \) or \( (10, 0) \), \( C \) always has an effective even theta characteristic. Moreover, \( C \) has at least two effective even theta characteristics if and only if the period of \((X_{(S,C)}, \iota_{(S,C)}) \) lies in the characteristic Heegner divisor.

**Proof.** Since the period of \( C \) is exactly the image of \((X_{(S,C)}, \iota_{(S,C)}) \) by the Torelli map, the result follows from Theorem \ref{thm:main}. \( \square \)

**10. Spin-1/2 bosonization formula and a factorization of \( \tau_M \)**

In Section \ref{sec:bosonization} we introduce a twisted version \( \tau_{sp}^1 \) of \( \tau_M \) and give its explicit formula purely in terms of Borcherds products. The relations \ref{eq:bosonization}, \ref{eq:factorization} below provide a factorization of \( \tau_M \) at the level of holomorphic torsion invariants.

**10.1. Spin-1/2 bosonization formula.** Let \( C \) be a smooth projective curve of genus \( g \) and let \( \Sigma \) be its theta characteristic. The pair \((C, \Sigma) \) is called a spin curve. A theta characteristic \( \Sigma \) is ineffective if \( h^0(\Sigma) = 0 \). Let \( \omega \) be a Kähler form on \( C \). Then \( \Sigma \) is equipped with the Hermitian metric induced by \( \omega \). Let \( \tau(C, \Sigma; \omega) \) be the analytic torsion of \( \Sigma \) with respect to \( \omega \). Recall that \( \text{vol}(C, \omega) = \int_C \omega/2\pi \). We set

\[
\bar{\tau}_g(C, \Sigma) := \text{Vol}(C, \omega)\tau(C, \omega)\tau(C, \Sigma; \omega)^2.
\]

By the anomaly formula for Quillen metrics \cite{1}, if \( \Sigma \) is ineffective, \( \bar{\tau}_g(C, \Sigma) \) is independent of the choice of a Kähler form \( \omega \) on \( C \). Thus we get an invariant \( \bar{\tau}_g \) of ineffective spin curves of genus \( g \). In Section \ref{sec:bosonization} we recall the spin-1/2 bosonization formula \ref{eq:bosonization}, \ref{eq:factorization}, which gives an explicit formula for \( \bar{\tau}_g \) viewed as a function on the moduli space of ineffective spin curves of genus \( g \) with level 2-structure.

Let \( V \) be a fixed symplectic vector space of rank \( 2g \) over \( \mathbb{F}_2 \) equipped with a fixed symplectic basis \( \{e_1, \ldots, e_g, f_1, \ldots, f_g\} \). A level 2-structure on \( C \in \mathbb{M}_g \) is defined as an isomorphism of symplectic vector spaces \( \alpha: V \cong H_1(C, \mathbb{F}_2) \), where \( H_1(C, \mathbb{F}_2) \) is equipped with the intersection pairing. Let \( \text{Alb}(C)[2] \) (resp. \( \text{Pic}^0(C)[2] \)) be the 2-division points of the Albanese variety \( \text{Alb}(C) \) (resp. Picard variety \( \text{Pic}^0(C) \)). By the canonical isomorphism \( H_1(C, \mathbb{F}_2) \cong \frac{1}{2}H_1(C, \mathbb{Z})/H_1(C, \mathbb{Z}) \cong \text{Alb}(C)[2] \) and the
Abel-Jacobi isomorphism $\text{Pic}^0(C) \cong \text{Alb}(C)$, a level 2-structure on $C$ is identified with a symplectic basis of $\text{Pic}^0(C)[2]$ with respect to the Weil pairing.

Let $\mathcal{M}_g(2)$ be the moduli space of projective curves of genus $g$ with level 2-structure and let $p: \mathcal{M}_g(2) \to \mathcal{M}_g$ be the natural projection. Let $S_g^+$ be the moduli space of even spin curves of genus $g$ and let $\pi: S_g^+ \to \mathcal{M}_g$ be the natural projection. We define $S_g^+(2)$ as the fiber product $S_g^+ \times_{\mathcal{M}_g} \mathcal{M}_g(2)$. The projection from $S_g^+(2)$ to $\mathcal{M}_g(2)$ (resp. $S_g^+$) is denoted again by $p$ (resp. $\pi$). The covering $p: S_g^+(2) \to \mathcal{M}_g(2)$ of degree $2^{g-1}(2g + 1)$ is trivial as follows. On $(C, \alpha) \in \mathcal{M}_g(2)$, there is a distinguished even theta characteristic $\kappa \in \text{Pic}^{g-1}(C)$ called Riemann’s constant (e.g. [13, p.6 and Lemma 1.5]). For every even pair $(a, b), a, b \in \{0, 1/2\}^g$, we define a section $\sigma_{a,b}: \mathcal{M}_g(2) \to S_g^+(2)$ by $\sigma_{a,b}(C, \alpha) := (C, \kappa \otimes \chi_{a,b}, \alpha)$, where $\chi_{a,b} \in \text{Pic}^0(C)[2]$ is the point corresponding to $\sum_i 2a_i \xi_i + \sum_i 2b_i \bar{\xi}_i \in F^{2g}$ via the isomorphism $F^{2g} \cong \text{Pic}^0(C)[2]$ induced by $\alpha$. In this way, we get a decomposition $S_g^+(2) = \bigcup_{(a,b)} \sigma_{a,b}(\mathcal{M}_g(2))$. We set $S_g^+(0)(2) := \bigcap_{(a,b)} \sigma_{a,b}(\mathcal{M}_g(2))$ and $S_g^+(0) := \bigcup_{(a,b)} \sigma_{a,b}(\mathcal{M}_g(2))$. Since $\kappa(\alpha \otimes \chi_{a,b}) = 0$ if and only if $\chi_{a,b}(\Omega(C)) \neq 0$ for $(C, \alpha) \in \mathcal{M}_g(2)$, $\tau_g$ is a function on $S_g^+(0)$.

On the other hand, for every even pair $(a, b)$, the theta constant $\theta_{a,b}$ is a section of a certain line bundle on $\mathcal{M}_g(2)$ and its Petersson norm $\|\theta_{a,b}\|$ is a function on $\mathcal{M}_g(2)$. For $g = 0$, we define $\|\theta_{a,b}\| := 1$. Let $\zeta_Q(s)$ be the Riemann zeta function. By the spin-1/2 bosonization formula [2, 11, 13, Th 4.9 (i), p.94 Eq. (4.58), p.97 Eq. (5.7)], the following equality of functions on $\mathcal{M}_g(2) \setminus \text{div}(\theta_{a,b})$ holds:

$$\sigma_{a,b}^* \pi^* \tau_g = c_g \|\theta_{a,b}\|^{-4}, \quad c_g := (4\pi)^{-g} e^{6(1-g)(2\zeta(1)-\zeta(1))},$$

where $c_g$ is evaluated by the arithmetic Riemann-Roch theorem [16] for $g = 0$, by Kronecker’s limit formula and Ray-Singer’s formula [30, Th. 4.1] for $g = 1$, by and Wentworth’s formula [33, Eq. (1.1) and Cor. 1.1] for $g \geq 2$. In other words,

$$\text{Vol}(C, \omega)^{\tau(C, \omega) \tau(C, \kappa \otimes \chi_{a,b}; \omega)^2} = c_g \|\theta_{a,b}(\Omega(C))\|^{-4}$$

for all $(C, \alpha) \in \mathcal{M}_g(2) \setminus \text{div}(\theta_{a,b})$ and even pairs $(a, b)$. Notice that the Laplacians (resp. volume) in [33] differ from ours by the scaling factor 2 (resp. $2\pi$). Hence Wentworth’s formula [33, Eq. (1.1) and Cor. 1.1] reads

$$\text{Area}(C, \omega)^2 \zeta_{\Omega}(0) \tau(C, \zeta_{\Omega}(0)) \tau(C, \kappa \otimes \chi_{a,b}; \omega)^2$$

$$= (4\pi)^{6(2\zeta(1)-\zeta(1))} e^{4(1-g)(2\zeta(1)-\zeta(1))} \|\theta_{a,b}(\Omega(C))\|^{-4},$$

where $\zeta_{\Omega}(s)$ (resp. $\zeta_{\Omega}(s)$) is the spectral zeta function of the Laplacian $(\bar{\partial} + \bar{\partial})^2$ acting on the smooth sections of $\mathcal{O}_C$ (resp. $\Sigma$) and Area$(C, \omega) := \int_C \omega$. Since

$$\zeta_{\Omega}(0) = \frac{\chi(C)}{6} - h^0(\mathcal{O}_C), \quad \zeta_{\Omega}(0) = \frac{\chi(C)}{3} + \frac{1}{2} \deg \Sigma - h^0(\Sigma) = \frac{g - 1}{6}$$

by [13, p.37 1.16] and since $\text{Vol}(C, \omega) = \text{Area}(C, \omega)/2\pi$, we get the value $c_g$ in (10.1).

Let us extend the definition of $\tau_g$ to disconnected curves as follows. A line bundle on a disconnected curve is a theta characteristic if it is a componentwise theta characteristic. Similarly, a theta characteristic on a disconnected curve is ineffective if it is componentwise ineffective. In what follows, for a disjoint union of smooth projective curves $C = \bigcup_{i \in I} C_i$ with $g(C_i) := g_i$, and an ineffective theta characteristic $\Sigma = \{\Sigma_i\}_{i \in I}$ on $C$, we define

$$\tilde{\tau}_g(C, \Sigma) := \prod_{i \in I} \tilde{\tau}_{g_i}(C_i, \Sigma_i),$$
where \( g := \sum_{i \in I} g_i \) is the total genus of \( C \).

### 10.2. A factorization of \( \tau_M \).

We introduce the following twisted version of \( \tau_M \).

#### Definition 10.1.

Let \((X, \iota)\) be a 2-elementary \(K3\) surface of type \( M \) and let \( \gamma \) be an \( r \)-invariant Kähler form on \( X \). If \( M \not\equiv \mathbb{U}(2) \oplus E_8(2) \), define

\[
\tau_{M, \text{spin}}(X, \iota) := \prod_{\Sigma = K_{X, \iota}, h^0(\Sigma) = 0} \left\{ \text{Vol}(X, \gamma)^{\text{deg}(\tau_\iota)} \tau(c_{Y}(X, \gamma)(\iota)) \tau(X^\iota, \Sigma; \gamma|_{X^\iota})^{-2} \right\}
\]

\[
\times \exp \left[ \frac{1}{8} \int_{X^\iota} \log \left( \frac{\eta \wedge \bar{\eta}}{\gamma^2/2!} \right) \left( \frac{\text{Vol}(X, \gamma)}{\|\eta\|^2_{L^2}} \right) c_1(X^\iota, \gamma|_{X^\iota}) \right],
\]

where \( \Sigma \) runs over all ineffective theta characteristics on \( X^\iota \). If \( M \cong \mathbb{U}(2) \oplus E_8(2) \) and hence \( X^\iota = \emptyset \), define

\[
\tau_{M, \text{spin}}(X, \iota) := \tau_M(X, \iota)^2.
\]

Recall that the vector-valued modular form \( f_\Lambda \) of type \( \rho_\Lambda \) was defined by (9.5), (9.19) when \( r = 22 - r(\Lambda) = 2 \). We extend its definition to the case \( r \neq 2 \) by setting

\[
f_\Lambda := \delta_{r,10} F_\Lambda.
\]

Then Theorem 0.1 is interpreted as the modularity of \( \tau_{M, \text{spin}} \) as follows.

#### Theorem 10.2.

There exists a constant \( C'_M > 0 \) depending only on \( M \) such that the following equality of functions on \( M'_A \setminus H_\Lambda \) holds:

\[
(10.4) \quad \tau_{M, \text{spin}} = C'_M \|\Psi_\Lambda(\cdot, 2g^{-1} F_\Lambda + f_\Lambda)\|^{-1/2}.
\]

**Proof.** For a 2-elementary \( K3 \) surface \((X, \iota)\) of type \( M \) with \((r, l, \delta) \neq (10, 10, 0), (10, 8, 0)\), recall that \( X^\iota \) consists of a curve of genus \( g = g(M) \) and \( k = k(M) \) smooth rational curves (cf. Section 3.2).

*(Case 1)* If \((r, \delta) \neq (2, 0), (10, 0)\) and \( X^\iota \) has no effective even theta characteristics, we get

\[
(10.5) \quad \tau_{M, \text{spin}}(X, \iota) = \prod_{\Sigma = K_{X, \iota}, h^0(\Sigma) = 0} \tau(\iota) \tau(c_{Y}(X^\iota, \Sigma)) = \prod_{(a,b) \text{ even}} \left( \frac{\theta_{\Lambda}(\Omega(X^\iota))}{\|\theta_{\Lambda}(\Omega(X^\iota))\|}\right) \leq \frac{\tau_M(X, \iota)^{2g-1}(2g+1)}{12 \cdot \tau(\iota)_0} \|\theta_{\Lambda}(\Omega(X^\iota))\|^4 = c_M \tau_M(X, \iota)^{2g-1}(2g+1) \|\theta_{\Lambda}(\Omega(X^\iota))\|^4\]

with

\[
c_M := (c_g^{-1} - 1)^{2g-1}(2g+1) \{ (4\pi)^{g} e^{6(10-r)(2\zeta(1)+\zeta(1))} \}^{-2g-1}(2g+1).
\]

Here the first equality of (10.5) follows from Definition 10.1 and the second follows from 10.2. Comparing Theorem 0.1 and (10.5), we get (10.4) with \( (C'_M)^2 := c_M^2 / C_M \) in this case.

*(Case 2)* If \((r, \delta) = (2, 0), (10, 0)\) with \((r, l, \delta) \neq (10, 10, 0), (10, 8, 0)\) and if \( X^\iota \) has a unique effective even theta characteristic corresponding to a theta constant \( \theta_{a_0,b_0}(\Omega(X^\iota)) \) with respect to a suitable level 2 structure, we get in the same way (10.6)

\[
(10.6) \quad \tau_{M, \text{spin}}(X, \iota) = \prod_{\Sigma = K_{X, \iota}, h^0(\Sigma) = 0} \tau(\iota) \tau(c_{Y}(X^\iota, \Sigma)) = \prod_{(a,b) \neq (a_0,b_0), \text{even}} \left( \frac{\theta_{\Lambda}(\Omega(X^\iota))}{\|\theta_{\Lambda}(\Omega(X^\iota))\|}\right) \leq \frac{\tau_M(X, \iota)^{2g-1}(2g+1)}{12 \cdot \tau(\iota)_0} \|\theta_{\Lambda}(\Omega(X^\iota))\|^4 = c_M \tau_M(X, \iota)^{2g-1}(2g+1) \|\theta_{\Lambda}(\Omega(X^\iota))\|^4\]

\]
with
\[c_M := (\xi_0^{-k} \xi_g^{-1}) (2^g-1)(2^{g-1}+1) = \left\{ (4\pi)^2 e^{6(10-r)}(2\zeta(1-1)+\zeta(1)) \right\} - (2^g-1)(2^{g-1}+1).\]

By Theorem 10.1 and (10.6), we get (10.4) with \((C_M')^2 := c_M^2 / C_M\) in this case.

(Case 2) If \((r, l, \delta) = (10, 10, 0)\), then \(X^t = \emptyset\). Since we defined \(g = 1\) in this case, we get (10.4) with \((C_M')^2 := C_M^{-1}\) by Definition 10.1 and Theorem 0.1. If \((r, l, \delta) = (10, 8, 0)\), then \(X^t\) consists of two disjoint elliptic curves. In the same way as in (10.6), we get (10.3) with \((C_M')^2 := c_M^2 / C_M\), \(c_M = (\xi_1^{-2})^6 = (4\pi)^{-18}\) in this case. This completes the proof.

\[\square\]

Remark 10.3. Assume \(H_{\Lambda} \neq \emptyset\). As the period of a 2-elementary \(K3\) surface of type \(M\) approaches to a point of \(H_{\Lambda}\), one of the ineffective even theta characteristics on its fixed curve becomes effective in the limit and the value \(\tau_{M}^{\text{spin}}\) jumps there. Because of this jumping, \(\tau_{M}^{\text{spin}}\) is a discontinuous function on \(M_{\Lambda}^1\). Since \(\|\Psi_{\Lambda}(\cdot, 2^{g-1}F_{\Lambda} + f_{\Lambda})\|\) is also discontinuous along \(H_{\Lambda}\) by [33, Th. 1.1 (i)], it is an interesting problem of comparing \(\tau_{M}^{\text{spin}}\) and \(\|\Psi_{\Lambda}(\cdot, 2^{g-1}F_{\Lambda} + f_{\Lambda})\|\) on the locus \(H_{\Lambda}\).
