Downlink Scheduling over Markovian Fading Channels

Wenzhuo Ouyang, Atilla Eryilmaz, and Ness B. Shroff

Abstract—We consider the scheduling problem in downlink wireless networks with heterogeneous, Markov-modulated, ON/OFF channels. It is well-known that the performance of scheduling over fading channels relies heavily on the accuracy of the available Channel State Information (CSI), which is costly to acquire. Thus, we consider the CSI acquisition via a practical ARQ-based feedback mechanism whereby channel states are revealed at the end of only scheduled users' transmissions. In the assumed presence of temporally-correlated channel evolutions, the desired scheduler must optimally balance the exploitation-exploration trade-off, whereby it schedules transmissions both to exploit those channels with up-to-date CSI and to explore the current state of those with outdated CSI.

In earlier works, Whittle’s Index Policy had been suggested as a low-complexity and high-performance solution to this problem. However, analyzing its performance in the typical scenario of statistically heterogeneous channel state processes has remained elusive and challenging, mainly because of the highly-coupled and complex dynamics it possesses. In this work, we overcome these difficulties to rigorously establish the asymptotic optimality properties of Whittle’s Index Policy in the limiting regime of many users. More specifically: (1) we prove the local optimality of Whittle’s Index Policy, provided that the initial state of the system is within a certain neighborhood of a carefully selected state; (2) we then establish the global optimality of Whittle’s Index Policy under a recurrence assumption that is verified numerically for our problem. These results establish that Whittle’s Index Policy possesses analytically provable optimality characteristics for scheduling over heterogeneous and temporally-correlated channels.

I. INTRODUCTION

Channel fluctuation is an intrinsic characteristic of wireless communications. Such a variation calls for allocation of the wireless resources in a dynamic manner, leading to the classic opportunistic scheduling principle (e.g., [1][2]). Under the assumption that the instantaneous channel state information (CSI) is fully available to the scheduler, many efficient opportunistic scheduling algorithms (e.g., [4]-[6]) have been proposed and extensively studied.

More recent works have focused on designing scheduling algorithms under imperfect CSI, where the channel state is modeled as independent and identically distributed (i.i.d.) processes across time (e.g., [9]-[13]). On the other hand, although the i.i.d. channel model brings ease of analysis, it fails to capture the time-correlation of the fading channels [3]. Specifically, it fails to exploit the channel memory, which is a critical resource for making scheduling decisions. However, designing efficient scheduling schemes under time-correlated channels with imperfect CSI is a very challenging problem. The challenge is mainly because of the difficulty in making the classic ‘exploitation versus exploration’ trade-off (e.g., [7], [8]), in which a scheduler needs to strike a balance between selecting the channels with up-to-date channel memory that guarantees high immediate gains, or to explore the channels with outdated CSI for more informed decisions and associated future throughput gains.

We consider the downlink scheduling problem where a base station transmits to the users within its transmission range, subject to scheduling constraints. To model the time correlations present over fading channels, we assume that wireless channels evolve as Markov-modulated ON/OFF processes. The channel state information is obtained from ARQ-based feedback, only after each scheduled transmission. Nevertheless, due to time correlation, the memory of the past channel state can be used to predict the current channel state prior to scheduling decision. Hence, channel memory should be intelligently exploited by the scheduler in order to achieve high throughput performance.
In a related work [14], a similar problem is considered under delayed CSI, where it is assumed that perfect CSI is available within a maximum delay, which is in turn smaller than the delay experienced by the ARQ feedback used for collision detection. These assumptions allow the scheduling decisions to be decoupled from CSI acquisition, which leads to the development of centralized as well as distributed schedulers. However, this approach does not use ARQ as a means of acquiring improved channel quality information. In contrast, in our setup the nature of ARQ feedback creates an implicit impact of scheduling decisions on the CSI feedback, which completely transforms the nature of the optimal scheduler design, and therefore requires a different approach. Under the scenario where all the channels have identical Markov statistics, round-robin-based algorithms (e.g., [15]–[18]) have been shown to possess optimality properties in throughput performance. However, the round-robin-based algorithms are no longer optimal in asymmetric scenarios, e.g., when different channels have different Markov transition statistics, as is naturally the case in typical heterogeneous conditions.

Under the asymmetric scenarios, our downlink scheduling problem is an example of the classic Restless Multiarmed Bandit Problem (RMBP) [19]. Low-complexity Whittle’s Index Policies [19] for the downlink scheduling problem have been proposed in [20],[21] based on RMBP theory. However, although Whittle’s Index Policy can bring significant throughput gains by exploiting the channel memory [21], the analytical characterization of its performance under asymmetric scenarios is very challenging and prohibitively technical. This is because asymmetry leads to a sophisticated interplay of memory evolution among channels with heterogeneous characteristics, which brings a significant challenge to the analysis of Whittle’s Index Policy not present in the perfectly symmetric scenario.

For RMBP problems under general scenarios, Whittle’s Index Policy has been proven in [22] to be asymptotically optimal as the number of users grows, provided a non-trivial condition, known as Weber’s condition, holds. Nonetheless, Weber’s condition concerns the global convergence of a non-linear differential equation, which is extremely difficult to verify even numerically in our downlink scheduling scenario. In [23], optimality properties of general RMBP is studied, where a sub-optimal BALANCED-INDEX policy, as well as a THRESHOLD-WHITTLE policy, are proved to provide 2-approximation performance, i.e., achieves at least half of the optimal reward. Our work takes a different approach than [23] to specifically study the per-user throughput performance of the Whittle’s Index Policy for downlink scheduling, and consider the strict optimality metric in the asymptotic regime when the number of users scales.

In this paper, we take significant steps in analyzing the optimality properties of Whittle’s Index Policy for the downlink scheduling problem in the presence of channel heterogeneity. Specifically, our contributions are as follows.

- We apply the Whittle’s index framework to our downlink scheduling problem and identify the optimal policy for the problem with a relaxed constraint in Section III. This policy, with carefully selected randomization, provides a performance upper bound to Whittle’s Index Policy.

- We establish the local optimality of Whittle’s Index Policy in the asymptotic regime when the number of users scales in Section V. Specifically, we show that the performance of the index policy can get arbitrarily close to that of the relaxed-constraint optimal policy, provided that the initial state of the system is within a certain neighborhood of a carefully selected state.

- Based on the local optimality result, under a numerically verifiable recurrence assumption, we then establish the global optimality of Whittle’s Index Policy in the limiting regime of many users in Section VI.

II. SYSTEM MODEL AND PROBLEM FORMULATION

A. Downlink Wireless Channel Model

We consider a time-slotted, wireless downlink system with one base station and \( N \) users. The wireless channel \( C_i[t] \) between base station and user \( i \) remains static within each time slot \( t \) and evolves stochastically across time slots, independently across users. We adopt the simplest non-trivial model of time-correlated fading channels by considering two-state ON/OFF channels, where the state space of channel \( i \) is \( S_i = \{0, 1\} \), with the value of each state representing the transmission rate a channel can support at the state.

One important component of our model is the inclusion of channel heterogeneity that the users will typically experience in real systems. Such asymmetry creates a significant challenge to the design and analysis of optimal scheduling schemes compared to perfectly symmetric channels. To avoid cumbersome notation and unessential technical complications, in this work, we model channel asymmetry by considering only two classes of channel statistics. Specifically, for all
the channels in class $k$, $k=1,2$, their states evolve according to the same Markov statistics. However, these characteristics differ between classes. The state transition of channels in class $k$ is depicted in Fig. 1, represented by a $2 \times 2$ probability transition matrix,

$$
P_k = \begin{bmatrix} p_k & 1 - p_k \\ r_k & 1 - r_k \end{bmatrix},
$$

where

$$p_k := \text{prob}(C_i[t]=1 \mid C_i[t-1]=1),$$

$$r_k := \text{prob}(C_i[t]=1 \mid C_i[t-1]=0).$$

for channel $i$ in class $k$. The number of class $k$ channels is $\gamma_k N$, $k \in \{1, 2\}$ with $\gamma_k$ being the proportion of channels in class $k$ with respective to the total number $N$ of channels.

We study the scenario where all the Markovian channels are positively correlated, i.e., $p_k > r_k$ for $k=1,2$. This assumption, which is commonly made in this domain (e.g., [17], [18], [24]), means that the channel evolution has a positive auto-correlation. Hence, roughly speaking, the channel has a stronger potential to stay in its previous state than jumping to another, which is typical especially in slow fading environment. For ease of exposition, we shall exclude the trivial case when $r_k=0$ or $p_k=1$, $k=1,2$.

**B. Scheduling Model – Belief Value Evolution**

We assume that the base station can simultaneously transmit to at most $\alpha N \in \mathbb{Z}^+$ users in a time slot without interference, where $\alpha \in (0,1]$ stands for the maximum fraction of users that can be activated. For example, in a multi-channel communication model, $\alpha$ would correspond to the fraction of all users that can be simultaneously serviced in unit time. However, the scheduler does not know the exact channel state in the current slot when the scheduling decision is made. Instead, the scheduler maintains a belief value $\pi_i[t]$ for each channel $i$, which is defined as the probability of channel $i$ being in the ON state at the beginning of slot $t$. The accurate channel state is revealed via ACK/NACK feedback from the scheduled users, only at the end of each time slot after the data is transmitted. This accurate channel state feedback is in turn used by the scheduler to update the belief values.

For user $i$ in class $k$, $k=1,2$, let $a_i[t] \in \{0,1\}$ indicate whether the user is selected for transmission in slot $t$. Then, from the definition the belief values, $\pi_i[t]$ evolves as follows,

$$\pi_i[t+1]= \begin{cases} p_k, & \text{if } a_i[t]=1, C_i[t]=1, \\ r_k, & \text{if } a_i[t]=1, C_i[t]=0, \\ \pi_i[t]p_k+(1-\pi_i[t])r_k, & \text{if } a_i[t]=0. \end{cases}$$

(1)

In our setup, belief values are known to be sufficient statistics to represent the past scheduling decisions and feedback (e.g., [16], [25]). In the meanwhile, in our ON/OFF channel model, $\pi_i[t]$ also equals to the expected throughput contributed by channel $i$ if it is scheduled in time slot $t$.

For a user in class $k$, $k=1,2$, we use $b^k_{c,l}$ to denote its belief value when the most recent observed channel was $c \in \{0,1\}$, and is $l$ slots in the past. From the belief update rule (1), $b^k_{c,l}$ can be calculated as a function of $l \geq 1$ as,

$$b^k_{0,l} = \frac{r_k-(p_k-r_k)^lr_k}{1+r_k-p_k}, \quad b^k_{1,l} = \frac{r_k+(1-p_k)(p_k-r_k)^l}{1+r_k-p_k}.$$

Fig. 2 illustrates the belief value update when a channel stays idle (i.e., $a_i=0$). It is clear that if the scheduler is never updated of the state of channel $i$ (in class $k$), the belief value will converge to its stationary probability of being ON, denoted by the stationary belief value $b^k_s := \lim_{l \to \infty} b^k_{c,l}$.

The vector $\vec{\pi}[t]=(\pi_1[t], \cdots, \pi_N[t])$ denotes the belief values of all channels at the beginning of slot $t$. We use $B_k$ to represent the set of the belief values for class $k$ channels, where $B_k=\{b^k_s, b^k_{c,l}, c \in \{0,1\}, l \in \mathbb{Z}^+\}$.

We assume that the system starts to operate from slot $t=0$. At the beginning of slot 0, for each channel the scheduler has either observed its channel state before, or has never been updated of its channel state, i.e., with belief value $b^k_s$. It is then clear that, based on the belief update rule (1), $\pi_i[t] \in B_k$ for all $t \geq 0$, i.e., each belief value $\pi_i[t]$ evolves over countably many states.

In the rest of the paper, we shall use ‘belief value’ and ‘belief state’ interchangeably.

**C. Downlink Scheduling Problem – POMDP Formulation**

We consider the broad class $U$ of (possibly non-stationary) scheduling policies that makes a scheduling...
The downlink scheduling problem is then to identify a policy in $U$ that maximizes the infinite horizon, time average expected throughput, subject to the constraint on the number of users selected at each time slot. Given the initial state $\pi[0]$, the problem is formulated as,

$$\max_{u \in U} \liminf_{T \to \infty} \frac{1}{T} E \left[ \sum_{t=0}^{T-1} \sum_{i=1}^{N} \pi_i[t] \cdot a_i^u[t] \right] \pi[0]$$

(2)

subject to

$$\sum_{i=1}^{N} a_i^u[t] \leq \alpha N, \quad \forall t.$$  
(3)

where the belief value $\pi_i[t]$ evolves according to rule (1) based on the scheduling decision $a_i^u[t]$ under policy $u$. Such an objective is standard in literature for Markov Decision Processes under the long term average reward criteria (e.g., [26]). Noting that since the scheduling decisions are made based on incomplete knowledge of channel states, this problem is a Partially Observable Markov Decision Process [25].

This problem is in fact an example of Restless Multiarmed Bandit Problem (RMBP) [19]. For a general RMBP, finding an optimal solution is PSPACE-hard [27]. However, for the downlink scheduling problem at hand, a low-complexity Whittle’s Index Policy was proposed in [20][21] based on the RMBP theory that inherently exploits the channel memory when making scheduling decisions. For detailed descriptions of general RMBP and Whittle’s Index Policy for downlink scheduling, please refer to [19][21].

For the downlink scheduling problem, we note that there is only limited analytical characterization of Whittle’s Index Policy, which is restricted in perfectly symmetric scenarios where Whittle’s Index Policy takes a special round-robin form [20]. In asymmetric cases, however, the scheduling decision no longer takes the form of round-robin, bringing sophisticated complications in belief value evolutions that are tightly coupled among channels, which significantly complicates the analysis. The main focus of this paper is to analytically characterize the performance of Whittle’s Index Policy in the asymmetric case with two classes of channels.

III. UPPER BOUND ON ACHIEVABLE THROUGHPUT

We begin our analysis by characterizing an upper bound to the throughput performance of all feasible downlink scheduling policies that satisfies the constraint (3). The upper bound is obtained from a fictitious policy which is optimal for the downlink scheduling problem under a relaxed constraint.

Note here that such relaxation is also a crucial step in the study of the general RMBP problem. Yet, our analysis, being specific to the downlink scheduling problem, has its novelties, as we shall remark on later.

A. Average-Constrained Relaxed Scheduling Problem

We consider an associated relaxed problem of (2)-(3) that only requires an average number of users to be activated in the long run, defined as follows

$$\max_{u \in U} \liminf_{T \to \infty} \frac{1}{T} E \left[ \sum_{t=0}^{T-1} \sum_{i=1}^{N} \pi_i[t] \cdot a_i^u[t] \right] \pi[0]$$

(4)

subject to

$$\limsup_{T \to \infty} \frac{1}{T} E \left[ \sum_{t=0}^{T-1} \sum_{i=1}^{N} a_i^u[t] \right] \leq \alpha N.$$  
(5)

Note that, contrary to the stringent constraint (3), the relaxed constraint (5) allows the activation of more than $\alpha$ fraction of users in each time slot, provided the long term average fraction does not exceed $\alpha$. Hence the optimal policy under this relaxed constraint, which we shall identify next, provides a throughput upper bound to any policy that satisfies the stringent constraint.

B. Optimal Policy for the Relaxed Problem

We remark that the relaxed problem is also an important component of Whittle’s analysis of general RMBPs [19], in which an optimal policy for the relaxed problem is developed based on the Whittle’s index values. Following the approach of classic RMBP framework [19], in our downlink scenario, we identify an optimal policy for the relaxed problem based on Whittle’s indices.

Specifically, for channels in class $k$, the Whittle’s index value $W_k(\pi)$ is assigned to each belief state $\pi \in B_k$. These index values intuitively capture the exploitation and exploration value to be gained from scheduling the associated channel when its belief value is $\pi$. This characteristic of $W_k(\pi)$ is also illustrated in
Section VII-B via numerical investigations. The index value function is expressed in closed form as

\[ W_k(\pi) = \begin{cases} 
\frac{(b^k_{0,i} - b^k_{0,i+1})(1+1) + b^k}{1-p_k + (b^k_{0,i} - b^k_{0,i+1})(1+1) + b^k_{0,i+1}} & \text{if } r_k \leq \pi = b^k_{0,i} < b^k_{i+1} \\
(1-p_k)(1+r_k-p_k) + r_k & \text{if } b^k_{i+1} \leq \pi \leq p_k 
\end{cases} \]  

(6)

Note that the above expression is a modified version of the expression in [20]. Details of the derivation can be found in [23].

The following two characteristics they possess are primarily significant for our analysis:

- \( W_k(\pi) \) monotonically increases with \( \pi \in B_k \).
- \( W_k(\pi) \in [0,1] \) for all \( \pi \in B_k \).

The next lemma identifies an index-based policy with appropriate randomization that is optimal for the relaxed constraint problem. This policy schedules each user based on its own belief value, independently from other users. The proof of the Lemma can be found in [20].

**Lemma 1.** For the problem under relaxed constraint, there exists an optimal stationary policy \( \phi^\ast \), parameterized by the threshold \( \omega^\ast \) and a randomization parameter \( \rho^\ast \in (0,1) \), such that

(i) Channel \( i \) in class \( k \) is scheduled if \( W_k(\pi_i[t]) > \omega^\ast \), and stays idle if \( W_k(\pi_i[t]) < \omega^\ast \). If \( W_k(\pi_i[t]) = \omega^\ast \), it is scheduled with probability \( \rho^\ast \).

(ii) The parameters \( \omega^\ast \) and \( \rho^\ast \) are such that, under policy \( \phi^\ast \), the relaxed constraint [5] is strictly satisfied with equality.

From now on, we shall denote \( \phi^\ast \) as the ‘Optimal Relaxed Policy’. For technical purposes, we henceforth assume \( \alpha \) is such that \( \rho^\ast \neq 1 \). Since each \( \alpha \) value maps to a unique \( (\omega^\ast, \rho^\ast) \) pair [29], only countably many \( \alpha \) values correspond to \( \rho^\ast = 1 \), i.e., achieved by deterministic policies. Therefore, the set of \( \alpha \in (0,1) \) for which \( \rho^\ast = 1 \) has Lebesgue measure one.

**C. Steady State Distribution of Belief Values**

We next present the transition structure of the belief values under Optimal Relaxed Policy, captured in the following lemma. The structure will be critical in the development of our subsequent main results.

**Lemma 2.** For each channel in class \( k \), under the Optimal Relaxed Policy, the structure of belief value evolution depends on the threshold \( \omega^\ast \) of policy.

(i) If \( \omega^\ast \geq W_k(b^k) \), the belief value evolution is transient. With probability 1, ultimately no channel in class \( k \) will transmit.

**Proof:** The proof of this lemma follows from the monotonic structure of belief evolution, as shown in Fig. 2 Details are included in Appendix [14].

Thus, if \( \omega^\ast \geq \max\{W_1(b^k), W_2(b^k)\} \), the above analysis reveals that ultimately no user transits, corresponding to the trivial case of \( \alpha N = 0 \). Also, if \( \omega^\ast \) is between \( W_1(b^k) \) and \( W_2(b^k) \), the class with the smaller \( W_k(b^k) \) will eventually transit into a passive mode, hence reducing the system to a well-understood scenario with a single class of channels [15][16]. Thus, here we focus on the heterogeneous case of \( \omega^\ast < W_k(b^k), k=1,2 \), where the steady-state belief value distribution exists for both classes under the Optimal Relaxed Policy.

**D. Upper bound on achievable throughput**

The throughput performance of Optimal Relaxed Policy provides an throughput upper bound for all policies under the stringent constraint. The value of such an upper bound clearly depends on the number of users in each class \( \gamma_k N, k=1,2 \), as well as the fraction \( \alpha \) of users allowed for activation. Denoting \( \gamma = [\gamma_1, \gamma_2] \), we represent the time average expected throughput of the Optimal Relaxed Policy as \( \nu^N(\gamma, \alpha) \). The following lemma states that, as long as \( \gamma \) and \( \alpha \) are given, the per-user throughput (i.e., \( \nu^N(\gamma, \alpha)/N \)) is independent of \( N \).

**Lemma 3.** Given \( \gamma \) and \( \alpha \), \( \nu^N(\gamma, \alpha)/N \) is independent of \( N \), denoted henceforth as \( r(\gamma, \alpha) \).

**Proof:** The proof follows from showing that, when the number of users \( N \) grows, as long as the proportion of each class of channels stays the same and the fraction \( \alpha \) of users activated does not change, the form of Optimal Relaxed Policy does not change. Since each user is scheduled independently, the throughput \( \nu^N(\gamma, \alpha) \) is proportional to \( N \), establishing the lemma. Details are provided in Appendix [15].

We hence refer to the \( (\gamma, \alpha) \) pair as ‘system parameters’. Therefore \( N r(\gamma, \alpha) \) provides a throughput upper bound to any policy in the same system under the stringent constraint [3]. Equivalently, \( r(\gamma, \alpha) \) provides a per-user throughput performance upper bound to all policies that satisfies the stringent constraint.

We next describe Whittle’s Index Policy for the strictly-constrained problem (2)-(4), and later study the closeness of its performance to the upper bound established here.
IV. WHITTLE’S INDEX POLICY DESCRIPTION

In this section we formally introduce Whittle’s Index Policy for solving the stringently-constrained downlink scheduling problem (2)-(3).

A. Whittle’s Index Policy

The Optimal Relaxed Policy, along with the Whittle’s index values, gives consistent ordering of belief values with respective to the indices. For instance, under the Optimal Relaxed Policy, if it is optimal to schedule one channel, it is then optimal to transmit to other channels with higher index values. So the Whittle’s index value gives an intuitive order of how attractive the channel is for scheduling. This intuition leads to Whittle’s Index Policy [20] under the stringent constraint on the maximum number of channels that can be scheduled.

Whittle’s Index Policy: At the beginning of each time slot, the channel \( i \) in class \( k \) is scheduled if its Whittle’s index value \( W_k (\pi_i) \) is within the top \( \alpha N \) index values of all channels in that slot, with arbitrary tie-breaking while assuring a total \( \alpha N \) channels being scheduled.

Whittle’s Index Policy is attractive because it has very low complexity, and it was observed via numerical investigations to yield significant throughput performance gains over the scheduling strategies that does not utilize channel memory [21]. The main focus of our work is to analytically understand the approximate or asymptotic optimality of Whittle’s Index Policy in asymmetric scenarios.

B. Whittle’s Index Policy over Truncated State Space

Recall from Section 11 that the belief values evolve over a countable state space, also note that if a channel is not scheduled for a long time, its belief value will get arbitrarily close to its stationary belief value. This motivates us to consider a truncated version of the belief value evolution whereby the belief value is set to its steady state if the corresponding channel is not scheduled for a large number, say \( \tau \), slots. This mild assumption facilitates more tractable performance analysis of the policy. Thus, if a class \( k \) user is not scheduled for \( \tau \) time slots, its channel state history is entirely forgotten and its belief value will transit to the stationary belief value \( b^k_s \), where the truncation \( \tau \) is assumed to be very large.

Whittle’s Index Policy is then implemented over the truncated belief state, which differs from the non-truncated case merely in the truncated belief value evolution. We believe that, the truncated scenario can provide arbitrarily close approximation to the original system when \( \tau \) is large. More importantly, as we shall see in the following two sections, Whittle’s Index Policy, implemented over the truncated belief state space, achieve asymptotically optimal performance as long as the truncation is sufficiently large.

V. LOCAL OPTIMALITY OF WHITTLE’S INDEX POLICY

In this section, we study the optimality properties of Whittle’s Index Policy for downlink scheduling, over a large truncated belief space. This result forms the basis for the subsequent global optimality result in Section 11. We start by introducing a state space over which the local optimality will be established.

A. System State Vector

We define the system state \( Z^N \) as a vector that represents the proportion of channels in each belief value, over the truncated space when the total number of users is \( N \), i.e., \( Z^N = [Z^1, Z^2, \ldots, Z^N] \), with

\[
Z^k [Z_{0,1}^k, \ldots, Z_{0,\tau}^k, Z_{s,1}^k, \ldots, Z_{s,1}^k, Z_{1,1}^k, \ldots, Z_{1,1}^k], k=1,2.
\]

where \( Z_{c,l}^k \) and \( Z_{s}^k \) respectively denote the proportion of channels in the corresponding belief state \( b^k_{c,l} \) and \( b^k_s \) with respect to the total number of users \( N \). Hence, each element of \( Z^N \) is a multiple of \( 1/N \) so that \( Z^N \) takes values in a lattice with mesh size \( 1/N \). Noting that the total number of users in each class does not change over time, for any \( N \) the system state \( Z^N[t] \in Z \) where

\[
Z : = \{ Z^N \geq 0 : \sum_{c,l} Z_{c,l}^k = \gamma_k, k=1,2 \}.
\]

The system state vector \( Z^N[t] \) does not distinguish users with the same belief state, thus its dimension will not scale with \( N \). Therefore, compared with \( \bar{\pi}[t] \), it provides a more convenient representation of the system belief state. Furthermore, \( Z^N[t] \) fully determines the instantaneous throughput gain in slot \( t \) under both Whittle’s Index Policy and the Optimal Relaxed Policy (introduced in Lemma 1), because the instantaneous throughput gains under both policies are only determined by the distribution of the channels with different belief values, not their identities.

From Lemma 2 and the subsequent remarks, under the operation of the Optimal Relaxed Policy, the belief state evolution of each channel is positive recurrent with a steady-state distribution. The following lemma also establishes the independence of this steady-state
distribution from \(N\), and defines a useful parameter for future use.

**Lemma 4.** Given the system parameters \((\gamma, \alpha)\), the system state vector \(Z^N[t]\) under the Optimal Relaxed Policy converges in distribution to a random vector, denoted as \(Z^N[\infty]\). The mean of \(Z^N[\infty]\) is independent of \(N\) and is denoted as

\[
\zeta^\alpha_\gamma := E\left[ Z^N[\infty] \right].
\]

**Proof:** This lemma follows from a similar principle to the one we established in Lemma 3. For details, please refer to Appendix D.

It is easy to see that \(\zeta^\alpha_\gamma \in Z\) and the form of \(\zeta^\alpha_\gamma\) fully determines the time average throughput of the Optimal Relaxed Policy. Therefore, the vector \(\zeta^\alpha_\gamma\) provides an important benchmark for our asymptotic analysis. If, in the long run under Whittle’s Index Policy, the system state \(Z^N[t]\) stays close to \(\zeta^\alpha_\gamma\), it indicates that Whittle’s Index Policy will have throughput performance close to that of the Optimal Relaxed Policy—the throughput upper bound. To capture the closeness, we define the \(\delta\) neighborhood of \(\zeta^\alpha_\gamma\) as

\[
\Omega_\delta(\zeta^\alpha_\gamma) = \{Z \in Z : ||Z - \zeta^\alpha_\gamma|| \leq \delta\}, \tag{8}
\]

for \(\delta > 0\), where \(|| \cdot ||\) stands for Euclidean distance. We are now ready to state and prove our first main result regarding a form of local optimality of Whittle’s Index Policy.

**B. Local Optimality of Whittle’s Index Policy**

Under the system parameters \((\gamma, \alpha)\), we let \(R^N_T(\gamma, \alpha, x)\) represent the time average throughput obtained over the time duration \(0 \leq t < T\) under Whittle’s Index Policy, conditioned on the initial system state \(Z^N[0] = x\), i.e.,

\[
R^N_T(\gamma, \alpha, x) := \frac{1}{T} E\left[ \sum_{t=0}^{T-1} \sum_{i=1}^{N} \pi_i[t] a^\text{ind}_i[t] | Z^N[0] = x \right],
\]

where \((a^\text{ind}_i[t])_i\) denotes the scheduling decision vector made by Whittle’s Index Policy at time \(t\).

Recall from Lemma 3 that \(r(\gamma, \alpha)\) denotes the per-user throughput under the Optimal Relaxed Policy, which serves as an upper bound on Whittle’s Index Policy performance. The next proposition characterizes the local convergence property of Whittle’s Index Policy performance to \(r(\gamma, \alpha)\).

**Proposition 1.** Under the system parameters \((\gamma, \alpha)\), there exists a \(\delta > 0\) neighborhood \(\Omega_\delta(\zeta^\alpha_\gamma)\) of \(\zeta^\alpha_\gamma\) such that, if the initial system state \(x\) is within \(\Omega_\delta(\zeta^\alpha_\gamma)\), then

\[
\lim_{T \to \infty} \lim_{m \to \infty} \frac{R^N_T(\gamma, \alpha, x)}{N_m} = r(\gamma, \alpha),
\]

where \(\{N_m\}_m\) is any increasing sequence of positive integers with \(\alpha N_m, \gamma k N_m \in Z^+, k = 1, 2\) and all \(m\).

**Proof Outline:** Here, we give a high level description of the proof for an intuitive understanding, and refer the reader to Appendix D for the rigorous derivation.

- We start by defining a fluid approximation, whereby the discrete-time evolution of \(Z^N[t]\) under Whittle’s Index Policy is modeled as a deterministic vector \(z[t] \in Z\) that evolves in discrete time over \(Z\) and is independent of \(N\). Under this fluid approximation, the users are no longer unsplittable entities so that the state space of \(z[t]\) is no longer restricted to a lattice as it was for \(Z^N[t]\). Also, the fluid approximation \(z[t]\) evolves in a deterministic manner, in contrast to the stochastic transition of \(Z^N[t]\). The evolution of \(z[t]\) is defined by a difference equation as a function of the expected state change of \(Z^N[t]\) under Whittle’s Index Policy as follows

\[
z[t+1] - z[t] \bigg|_{z[t]=z} = E\left[ Z^N[t+1] - Z^N[t] \bigg| Z^N[t] = z \right], \tag{9}
\]

where \(N\) is any integer for which \(z\) is a feasible state.

- We then establish local convergence of the fluid approximation model when \(z[0]\) is within a small enough \(\delta\) neighborhood \(\Omega_\delta(\zeta^\alpha_\gamma)\) of \(\zeta^\alpha_\gamma\). We show the convergence by first noting that the differential equation (9) is linear within a wider convex region than \(\Omega_\delta(\zeta^\alpha_\gamma)\). Within this region, we obtain a closed form expression of the right hand side of (9), which enables us to investigate the eigenvalue structure of the linear differential equation. We show that each eigenvalue \(\lambda\) satisfies \(|\lambda| < 1\) and apply standard linear system theory to establish the local convergence.

- We then connect the fluid approximation model \(z[t]\) to the discrete-time stochastic system state \(Z^N[t]\) by using a discrete-time extension of Kurtz’s Theorem, which can be interpreted as an extension of the strong law of large numbers to random processes (see [30]). Essentially, it states that, over any finite time duration \([0, T]\), the actual system evolution \(Z^N[t]\) can be made arbitrarily close to the above fluid approximation \(z[t]\) by increasing the number of channels \(N\) sufficiently, with exponential convergence rate.

- The previous convergence result, together with the local convergence result of the fluid evolution \(z[t]\) to
ζγ, enables us to establish the local convergence of the 

system state ZN[t] to ζγ as the number of users N grows, provided that the initial state ZN[0] ∈ Ωδ(ζγ). Hence the system state under Whittle’s Index Policy will stay close (in a probabilistic sense) to the expectation ζγ of the system state under the Optimal Relaxed Policy, which, in turn, indicates that the throughput performance of Whittle’s Index Policy will approach the throughput upper bound r(γ, α), as expressed in the proposition.

We again emphasize that the technical details of the outlined steps are fairly intricate and are moved to Appendix D.

Proposition 1 illustrates an interesting local optimality property of Whittle’s Index Policy as the number of users scales. In fact, our result can be generalized to all state parameters (γ, α) stay the same. It indicates that, under Whittle’s Index Policy, as long as the initial state ZN[0] is close enough to ζγ, the average per-user throughput over any finite time duration will get arbitrarily close to the Optimal Relaxed Policy performance as the number of users scales.

**Remark:** We note that the sequence {Nm}m is used to guarantee that the number of channels in each class, as well as the number of scheduled users, take integer values. In fact, our result can be generalized to all N by slightly perturbing γ and α as a function of N but assuring their limits are well-defined.

VI. GLOBAL OPTIMALITY OF WHITTLE’S INDEX POLICY

The above local optimality result heavily relies on the initial state ZN[0] being close to ζγ, which is difficult to guarantee. In this section, we study the global optimality of the infinite horizon throughput performance of Whittle’s Index Policy starting from any initial state. We begin our analysis by presenting the recurrence structure of the system state.

**Lemma 5.** Under system parameters (γ, α), for any ϵ > 0, if the number of users N is large enough,

(i) The system state ZN[t] evolves as an aperiodic Markov chain, in a state space that contains only one recurrent class.

(ii) There exists at least one recurrent state within the ϵ neighborhood Ωε(ζγ) of ζγ.

**Proof:** We prove this lemma by constructing probability paths from any state to the neighborhood Ωε(ζγ). Details of the proof are included in Appendix E.

This lemma states that ZN[t] will ultimately enter any small neighborhood of ζγ when N is large enough. Together with Proposition 1, this result shows promise for establishing the global asymptotic optimality of Whittle’s Index Policy. This is plausible because once ZN[t] enters Ωδ(ζγ), the performance of Whittle’s Index Policy afterwards can get very close to its upper bound as N scales, as established in Proposition 1. However, since we consider the infinite horizon time average throughput, this argument would break down if the time it takes for ZN[t] to enter Ωδ(ζγ) also scales up with N. This observation motivates us to introduce a useful assumption, which will later be justified (in Section VII-A) via numerical studies.

**Assumption Ψ:** For each ϵ > 0, let Γx(N) represent the first time of reaching Ωε(ζγ) starting from ZN[0] = x, i.e.,

Γx(N) = min{t : ZN[t] ∈ Ωε(ζγ) | ZN[0] = x}.

Then we assume that, the expected time of reaching Ωε(ζγ) is bounded by a constant Mε < ∞, i.e.,

E[Γx(N)] ≤ Mε,

for all x and large enough N.

Since for each N, ZN[t] under Whittle’s Index Policy is recurrent and aperiodic with a finite state space, there exists a steady-state distribution associated with ZN[t]. As before, we use ZN[∞] to denote the associated limiting random vector. The next lemma establishes that, under Assumption Ψ, the distribution of ZN[∞] approaches a point-mass at ζγ as N scales. Here, again, the sequence {Nm}m is defined in the same way as in Proposition 1.

**Lemma 6.** Under Assumption Ψ and system parameters (γ, α), for any ϵ > 0, the steady state probability of ZN[t] under Whittle’s Index Policy satisfies

$$\lim_{m \to \infty} P(Z^{N_\infty} \in \Omega_\epsilon(\tilde{\zeta}_\gamma)) = 1.$$  

**Proof:** The proof utilizes Theorem 6.89 from [30], which builds on the following arguments.

Note that ϵ > 0 can be selected to be small enough for the following argument. As depicted in Fig. 3, we let Tε be a random variable denoting, in steady state, the time duration between consecutive hitting times into the neighborhood Ωε(ζγ) from outside of the neighborhood. Let T0ε denote the time duration from the time ZN[t] enters the neighborhood Ωε(ζγ) from outside until the time it leaves. Hence, the expected proportion of time that ZN[t] stays outside this neighborhood is (E[Tε] − E[T0ε])/E[Tε].
We know that the numerator \( E[T_\varepsilon] - E[T_\varepsilon^0] \) is uniformly bounded for all \( N \) due to Assumption \( \Psi \). However, as \( N \) increases, it is more likely for \( Z^N[t] \) to stay within the neighborhood for a long time before exiting it (based on the convergence of fluid approximation model and Kurtz’s Theorem in the proof of Proposition 1). Thus, \( E[T_\varepsilon^0] \), and hence the denominator \( E[T_\varepsilon] \), grow to infinity as \( N \) scales. Therefore, the expected proportion of time spent outside \( \Omega_\varepsilon(\zeta^N_N) \) vanishes as \( N \) scales up, which leads to the statement of the lemma. Details of the proof can be found in Appendix G.

Under Whittle’s Index Policy with system parameters \((\gamma, \alpha)\), we let \( R^N_x(\gamma, \alpha) \) be the achieved infinite horizon, time average throughput, conditioned on the initial system state \( Z^N[0] = x \), i.e.,

\[
R^N_x(\gamma, \alpha) := \lim_{T \to \infty} \frac{1}{T} E \left[ \sum_{i=1}^{T-1} \sum_{t=0}^{N} \pi_{i} | x_i^N(t) | Z^N[0] = x \right]
\]

From Lemma 6 we know that, in steady-state, the system state \( Z^N_m[\infty] \) is increasingly concentrated around \( \zeta^N_N \) as \( m \) increases, regardless of the initial state \( x \). We build on this to establish the global asymptotical optimality of Whittle’s Index Policy.

**Proposition 2.** Under Assumption \( \Psi \), for any initial system state \( x \), we have

\[
\lim_{m \to \infty} \frac{R^N_x(m)(\gamma, \alpha)}{N_m} = r(\gamma, \alpha).
\]

Since \( r(\gamma, \alpha) \) is an upper bound on the maximum achievable per-user throughput by any policy, this implies that Whittle’s Index Policy is optimal in the many user regime.

**Proof:** We prove this result by decomposing \( R^N_x(\gamma, \alpha) \) as a summation of the expected throughput conditioned on whether the system state is within or outside an arbitrarily small \( \epsilon \) neighborhood of \( \zeta^N_N \). Since the latter has diminishing probability according to Lemma 6 the expected throughput of Whittle’s Index Policy can get arbitrarily close to that of Optimal Relaxed Policy. Details of the proof are provided in Appendix G.

**Remarks:**

1) We would like to emphasize that the global optimality result is not a straight-forward extension of the local convergence result by contrasting Proposition 1 and Proposition 2. Note that in Proposition 1 the time limit is outside the limit of the number of users \( N \), where each convergence (with \( N \)) is with respect to a fixed time duration. However, the order of limit is switched in the global optimality result of Proposition 2 as it states the convergence with \( N \) the infinite horizon average throughput, which is much stronger and hence is much more challenging to prove.

2) We would like to contrast Assumption \( \Psi \) with Weber’s condition \([22]\). For general RMBP problem, Weber’s condition leads to the same global asymptotic optimality result. While confirming Weber’s condition may be possible in very low-dimensional problems, in our downlink scheduling problem, this requires one to rule out the existence of both closed orbits and chaotic behavior of a high-dimensional non-linear differential equation, which is extremely difficult to check - even numerically. Assumption \( \Psi \), on the other hand, takes a much simpler form, as it is defined over the actual stochastic system and is amenable to easy numerical verification, as is performed in Section VII-A.

**VII. Numerical Results**

**A. Verification and Interpretation of Assumption \( \Psi \)**

We start by numerically verifying Assumption \( \Psi \). We consider the asymmetric scenario with two classes of channels with system parameters \( \gamma = [0.45, 0.55], \alpha = 0.6 \), with \( p_1 = 0.9, r_1 = 0.45, p_2 = 0.8, r_2 = 0.3 \).
We next examine the change of the average hitting time $\Gamma_N^\alpha(\epsilon)$, while maintaining $\alpha$ and $\gamma$.

We let $x, y \in Z$ be initial values of $Z_N^N[0]$ that are selected to be two extreme points in the state space to exhibit the uniformity of $\Gamma_N^\alpha(\epsilon)$ to the initial state. Specifically, state $x$ corresponds to the case when all the users have just observed their channels to be in OFF state, i.e., with belief value $b_{01}^k$, $k=1,2$. And $y$ corresponds to the case when all users have no initial observation of their channels state history, i.e., with belief value $b_{01}^y$, $k=1,2$.

We examine the average value of hitting time $\Gamma_N^\alpha(\epsilon)$ and $\Gamma_N^\epsilon(\epsilon)$ with a very small neighborhood $\epsilon=0.005$, when the number of users $N$ grows from $10 \times 10^3$ to $500 \times 10^3$. As indicated in Fig. 4 for both cases, the average time of hitting the $\epsilon$ neighborhood first decreases with $N$, and then converges and stays almost the same as $N$ scales up. This is especially intriguing. The rationale behind this phenomenon is as follows. Under Whittle’s Index Policy, a total number of $\alpha N$ users are activated at each time slot. Therefore, for relatively small number of users, the amount of probabilistic belief state transitions, as well as the amount of system states in the neighborhood, increases with $N$, leading to a higher chance of hitting the desired neighborhood $\Omega_\epsilon(\bar{\zeta}_y)$ and smaller value of hitting time. However, the belief update of each user contributes to the $1/N$ change of the system state $Z_N^N[t]$, which decreases with $N$. Therefore, as $N$ further increases, the total amount of transitions of the system state $Z_N^N[t]$ due to channel state feedback is roughly $\alpha N - 1/N = 0$, which is invariant of $N$. Table I illustrates the average value of hitting time $\Gamma_N^\alpha(\epsilon)$ and $\Gamma_N^\epsilon(\epsilon)$ under a variety of randomly generated system parameters when $1\%$ convergence is reached as $N$ scales. These result shows that the hitting time is bounded and hence of verifies Assumption $\Psi$.

**B. ‘Exploitation versus Exploration’ Trade-off**

In this section, we demonstrate how the Whittle’s index value captures the ‘exploitation versus exploration’ trade-off for our asymmetric downlink scheduling problem.

Consider two classes of ON/OFF fading channels with belief value evolutions plotted in Fig. 5(a). Note that both classes have the same stationary distribution $b_{k}^c = 0.5$, $k \in \{1, 2\}$ of being at ON state, but channels in class 1 has a higher degree of time correlation, i.e., fades slower, than channels in class 2 since $p_1 > p_2$ and $r_1 < r_2$. The corresponding Whittle index values of the two classes of channels are depicted in Fig. 5(b) as functions of the updated belief value starting from different initial states.

To understand the nature of Whittle’s index value, we first consider the case when the channels in both classes are observed to be ON at time 0 and stay passive since then. As indicated in Fig. 5(a) the class
1 channel has a higher belief value than the class 2 channel, hence scheduling the class 1 channel gives a higher immediate throughput than scheduling the class 2 channel. Moreover, once a class 1 channel is scheduled, it is more likely to stay in ON state again, bringing high future gains. Accordingly, the index values in Fig. 5(b) when both state evolutions start from ON states capture that it is more attractive to schedule the class 1 channel because of the advantage in both exploitation and exploration.

On the other hand, when the scheduler has observed channels in both classes to be OFF at time 0, Fig. 5(a) shows that the class 2 channel has a higher belief value than the class 1 channel. However, although the Whittle’s index value in Fig. 5(b) of class 2 channel is initially smaller than that of class 1 channel, after a certain amount of delay (around 8 slots in the figure) this order is switched, which is interpreted as follows: initially, since the class 1 channel has smaller belief value than that of the class 2 channel, it is more attractive to exploit the immediate gain brought by the class 2 channel. However, as the passive time grows, as indicated in Fig. 5(a), the difference between immediate gain of both classes diminishes. Then, it becomes more attractive to explore the class 1 channel because its longer memory can bring higher future gains if it turns out to be in ON state.

This investigation reveals the intricate nature of Whittle’s index value in capturing the fundamental ‘exploration versus exploitation’ trade-off. In our scheduling problem with asymmetric channel statistics, such a property of Whittle’s Index Policy turns out to be crucial in achieving asymptotically optimal performance.

C. Performance Evaluation and Comparison

Note that our results focus on asymptotic regime when the number of users scales up. We next numerically evaluate the performance of the Whittle’s Index Policy under finite number of users. We next consider a system where \( \gamma = [0.6, 0.4], \alpha = 0.3, (p_1, r_1) = (0.75, 0.2) \) and \((p_2, r_2) = (0.8, 0.3)\), and evaluate the value \( R_y^{N}(\gamma, \alpha) / N \) when \( N \) increases as multiples of 5, i.e., \( N = 5m, m = 1, 2, \cdots \). Fig. 6(a) and (b) respectively correspond to the aforementioned extreme points. As observed in Fig. 6, the per-user throughput value \( R_y^{N}(\gamma, \alpha) / N \) of Whittle’s Index Policy quickly converges to the upper bound value \( r(\gamma, \alpha) \). This result indicates that, in realistic scenarios with finite \( N \), the global convergence result in Proposition 2 holds under moderate number of users (under \( N = 50 \) as shown in Fig. 5).

Fig. 6: Performance evaluation and comparison of per-user throughput of Whittle’s Index Policy. (a) \( Z^N[0] = x \); (b) \( Z^N[0] = y \). Fig. 6 also plots the per-user throughput performance of the BALANCEDINDEX policy, which is proposed in [23] and proved to achieve throughput half of the optimal throughput, i.e., 2-approximation performance. As observed in Fig. 6, the asymptotic per-user throughput performance of BALANCEDINDEX is strictly lower than the Whittle’s Index Policy. This is because although BALANCEDINDEX policy guarantees 2-approximation to the optimal throughput performance, it does not provide strictly optimal per-user throughput performance in the asymptotic regime of large number of users, as compared with Whittle’s Index Policy. Fig. 6 also evaluates the performance of a slight modification Whittle’s Index Policy, namely the THRESHOLD-WHITTLE policy, proposed in [24] by slightly adjusting the Whittles index value at belief values \( p_i, i = 1, 2 \). It can be observed from the figure that the per-user throughput performance of THRESHOLD-WHITTLE policy is very close to that of the Whittle’s Index Policy, indicating that the modification of the Whittle’s indices in THRESHOLD-WHITTLE policy does not bring significantly change the throughput performance for the plotted example. It was proven in [23] that the THRESHOLD-WHITTLE policy achieves at least half of the optimal throughput.
However, analytically proving the asymptotic optimality of THRESHOLD-WHITTLE policy remains an open question.

D. Evaluation of Fairness among Users

In this section, we evaluate the fairness performance of Whittle’s Index Policy. We exam the throughput difference between the two types of users, under different set of Markov transition statistics. To facilitate better evaluation, we define the throughput \( r_x^N(k, \gamma, \alpha) \) to be the per-user throughput within each class \( k \) of users, i.e.,

\[
\lim_{T \to \infty} \frac{1}{\gamma_k N} E \left[ \sum_{t=0}^{T-1} \sum_{i \in \mathcal{N}_k} \pi_i[t] a_i^{\text{ind}}[t] | Z^N[0] = x \right],
\]

where \( \mathcal{N}_k \) represents the set of users in class \( k \). We consider the scenario where \((p_1, r_1) = (0.9, 0.1)\) and \((p_2, r_2) = (0.6, 0.4)\) with \( \gamma = [0.5, 0.5], \alpha = 0.3 \). Therefore, the channels in class 1 have a much higher degree of correlation than the channels in class 2, i.e., it is more likely for the channels in class 1 to stay in its previous-slot state than change to a different state compared with channels in class 2. However, channels in both classes have the same steady state probability in state ‘1’, i.e., \( b_1^1 = b_2^1 = 0.5 \). Fig. 7 plots the per-user throughput within each class under Whittle’s Index Policy. It can be observed that users in class 1 achieves higher throughput than users in class 2. The higher throughput gain of class 1 is brought by the higher degree of temporal correlation and also the aforementioned ‘Exploitation versus Exploration’ trade-off. Since the class-1 channels have higher degree of time-correlation, if a class-1 channel is previously observed in state 1, the scheduler tends to continue to serve it for longer time to obtain high immediate gains. It is also more attractive to explore a channel in class 1 because, as previously discussed, higher future gains can be obtained if it turns out to be in state ‘1’. Therefore, channels in class 1 have higher overall throughput than channels in class 2, resulting in the big gap in throughput between the two classes of users in Fig. 7.

To facilitate better performance in terms of fairness, we evaluate the performance of the following heuristic policy \( \Xi \) based on the Whittle’s index values. In policy \( \Xi \), instead of directly using Whittle’s index values, the algorithm schedules the \( \alpha N \) users with the largest \( \frac{W_k(\pi_i[t])}{R_i[t]} \),

\[
\text{(a)} \quad \text{Average value of } r_x^N(1, \gamma, \alpha)
\]

\[
\text{(b)} \quad \text{Average value of } r_x^N(2, \gamma, \alpha)
\]

Fig. 7: Evaluation of \( r_x^N(k, \gamma, \alpha) \) with \( N \). (a) Whittle’s Index Policy; (b) Policy \( \Xi \).

at slot \( t \), where \( \tilde{R}_i[t] \) is user \( i \)'s achieved throughput up to slot \( t \), i.e., \( \tilde{R}_i[t] = \sum_{\tau=t-1}^{T-1} \pi_i[\tau] \cdot a_i^{\text{ind}}[\tau] | \pi[0] \). Hence a user’s priority for scheduling is determined by its Whittle’s index value relative to its own actual achieved throughput. Therefore policy \( \Xi \) mimics the proportional fair scheduling algorithms (e.g., [3]) commonly used in communication networks. Fig. 7(b) evaluates the performance of policy \( \Xi \). As we see, under the algorithm \( \Xi \), the throughput gap between the two classes of channels is closer than Whittle’s index policy, indicating improved fairness performance. Finally, we believe that combining Whittle’s index and the frame-based scheduling [18] can lead to low-complexity algorithms that optimally meet the fairness constraints among different users.

VIII. CONCLUSION

In this paper, we studied the problem of downlink scheduling over ON/OFF Markovian fading channels in the presence of channel heterogeneity. We consider the scenario where instantaneous channel state information is not perfectly known at the scheduler, but is
acquired via a practical ARQ-styled feedback after each scheduled transmission. We analytically characterized the performance of Whittle’s Index Policy for downlink scheduling, and proved its local and global asymptotic optimality properties as the number of users scales. Specifically, provided that the initial system state is within a certain region, we established the local optimality of Whittle’s Index Policy by investigating the evolution of the system belief state with a fluid approximation. We then established the global asymptotic optimality of Whittle’s Index Policy under a recurrence condition, which is suitable for numerical verification. Our results establish that Whittle’s Index Policy, which is attractive due to its low-complexity operation, also processes strong asymptotic optimality properties for scheduling over heterogeneous Markovian fading channels. Future research directions includes design of scheduling algorithms that not only maximizes the sum throughput, but also provides fairness among heterogeneous users using Whittle’s index.

Consider two systems with different total number of users but identical $\alpha$ and $\gamma$. Suppose the first system has $N_1$ total number of users while the second system has $N_2$ number of users. For the first system with $N_1$ total number of users, suppose the policy $\phi^*$, specified in Lemma 1 is optimal for the relaxed-constraint problem. For each channel $i$ in class $k$, we let $A_{\phi^*}^k$ denote the expected fraction of time of activation, i.e.,

$$A_{\phi^*}^k = \lim_{T \to \infty} \frac{1}{T} \mathbb{E} \left[ \sum_{t=0}^{T-1} a_{i}^{\phi^*} \mid t \right].$$

Then, according to Lemma 1(ii), the expected number of activated users satisfies

$$\gamma_1 N_1 \cdot A_{\phi^*}^1 + \gamma_2 N_1 \cdot A_{\phi^*}^2 = \alpha N_1.$$

Now apply the same policy $\phi^*$ when the total number of users is $N_2$. Since $\phi^*$ schedules each channel independently, $A_{\phi^*}^1$ and $A_{\phi^*}^2$ does not change in this scenario. Therefore, the expected number of activated users is expressed as

$$\gamma_1 N_2 \cdot A_{\phi^*}^1 + \gamma_2 N_2 \cdot A_{\phi^*}^2 = \frac{N_2}{N_1} \left[ \gamma_1 N_1 \cdot A_{\phi^*}^1 + \gamma_2 N_1 \cdot A_{\phi^*}^2 \right] = \alpha N_2,$$

hence the complementary slackness condition (i.e., Lemma 1(ii)) for the relaxed-constraint problem is also satisfied under $\phi^*$, when the total number of users is $N_2$. Hence the policy $\phi^*$ satisfies both Lemma 1(i) and (ii) under the total number of users $N_2$, and is an optimal policy for that scenario.

Therefore, fixing system parameters $(\gamma, \alpha)$, for different number $N$ of users, the policy $\phi^*$ is always optimal. Since the policy $\phi^*$ schedules each channel independently, we let $v_N(\gamma, \alpha)$ denote the expected reward contributed by each channel in class $k$. Hence we have

$$v_N(\gamma, \alpha) = N \gamma_1 v_1(\gamma, \alpha) + N \gamma_2 v_2(\gamma, \alpha).$$

Therefore the per-user throughput is

$$\frac{v^N(\gamma, \alpha)}{N} = \gamma_1 v_1(\gamma, \alpha) + \gamma_2 v_2(\gamma, \alpha),$$

which is independent of $N$. Hence the lemma is proven.
APPENDIX C
PROOF OF LEMMA 4

Given system parameters $(\gamma, \alpha)$, we know from the proof of Lemma 3 that the form of the Optimal Relaxed Policy, denoted by $\phi^*$, does not change with the number $N$ of users. Since $\phi^*$ schedules each channel independently, we let $\epsilon_k = [\epsilon_0^k, \cdots, \epsilon_{\tau}^k, \epsilon_{\tau+1}^k, \cdots, \epsilon_{1,1}^k]$ denote the steady state distribution of the belief value of a user in class $k$ under $\phi^*$, with $\epsilon_k^k + \sum_{c, h} \epsilon_{c,h}^k = 1$. Therefore,

$$E[Z^N(\infty)] = \frac{1}{N}[\gamma_1 N \epsilon_1, \gamma_2 N \epsilon_2] = [\gamma_1 \epsilon_1, \gamma_2 \epsilon_2].$$

Since $\phi^*$ is independent of $N$, $\epsilon_k$ is independent of $N$ for $k = 1, 2$. Therefore $E[Z^N(\infty)]$ is independent of the user number $N$, which proves the lemma.

APPENDIX D
PROOF OF PROPOSITION 1

A. Notations

We shall denote the $i$th element of $Z^N[t]$ as $Z_i^N[t]$, and let $\beta_i$ denote the corresponding belief value. The index value corresponding to $\beta_i$ is denoted as $w_i$. In this proof, since we are fixing the system parameters $(\gamma, \alpha)$, we shall drop the suffixes $\alpha$ and $\gamma$ to denote $\beta_i$ as $\beta_i$.

For ease of exposition, in this proof we assume $W_2(b_{0,0}^1) < W_1(b_{0,0}^1) = \omega^* < W_2(b_{0,0}^1)$. Hence, in the Optimal Relaxed Policy, channels in class 1 are activated when their belief values are above $b_{0,0}^1$, and stay idle if their belief values are below $b_{0,0}^1$, and activates with probability $\rho^* \in (0, 1)$ at $b_{0,0}^1$. For channels in class 2, they are activated when their belief values no smaller than $b_{0,0}^2$ and stay idle otherwise.

B. Transition properties of the system state

We first investigate the belief transition structure of the system state $Z^N[t]$ under the Whittle’s Index Policy. It is clear that $Z^N[t]$ evolves as a Markov Chain. We define the expected drift $\nabla Z^N[t]$ associated with the transition of $Z^N[t]$ as follows,

$$\nabla Z^N[t] = E[Z^N[t+1] - Z^N[t] \mid Z^N[t]].$$

For a channel with belief value $\beta_i$, we let $q^0_{i,j}$ and $q^1_{i,j}$ be the probability that its belief state changes to state $\beta_j$ under the idle and transmission actions, respectively. For example, if $\beta_i$ corresponds to belief value $b_{0,0}^1$, then $q^0_{i,i+1} = 1$ if the channel stays idle, otherwise $q^1_{i,1} = 1 - b_{0,0}^1$ and $q^1_{i,2r+1} = b_{0,0}^1$, which corresponds to the probability of observed channel being 0 or 1, respectively. Under the Whittle’s Index Policy, we let $g_i(z)$ be the fraction of users in belief value $\beta_i$ that are activated,

$$g_i(z) = \begin{cases} 
2(2\tau+1) & \text{if } \tau \leq i + \tau \leq 3\tau+1, \text{ and } j = i+1 \\
2(2\tau+1) & \text{if } \tau \leq i \leq 2\tau+1, \text{ and } j = i-1 \\
1 & \text{if } i = \tau + 1 \text{ or } 3\tau + 2, \text{ and } j = i
\end{cases}$$

We shall let $e_{ii} = 0$, and let $e_{ij}, i \neq j$ be a vector that has $-1$ at the $i$th element, $1$ at the $j$th element, and 0 at all other elements. Hence if a user changes its belief state from $\beta_i$ to $\beta_j$, the corresponding change of the system state $Z^N[t]$ is in the direction of $e_{ij}$ with scale $1/N$. Therefore, $\nabla Z^N[t]$ is a composition of expected changes in each direction $e_{ij}$. Suppose $Z^N[t] = z$, since the expected amount of change of $Z^N[t]$ in direction $e_{ij}$ is $z_i[t]q_{ij}(z[t])$, the expected drift $\nabla Z^N[t]$ can then be written as,

$$\nabla Z^N[t] \mid Z^N[t] = z = \sum_{i,j} z_i q_{ij}(z) \cdot e_{ij} := Q(z)z,$$

where the $(i, j)^{th}$ element of matrix $Q(z)$ is

$$Q_{ij}(z) = \begin{cases} 
-\sum_{j \neq i} q_{ij}(z) & \text{for } i = j, \\
q_{ij}(z) & \text{for } i \neq j
\end{cases}$$

Note that, although the system state $z$ can only take values on a lattice that depends on $N$, the matrix function $Q_{ij}(z)$ is defined over more general space $Z$. Based on this, we proceed to define a fluid approximation model.
C. Fluid Approximation Model

We consider a fluid approximation model \( z[t] \), which is defined by the following difference equation

\[
\begin{align*}
  z[t + 1] - z[t] &= Q(z[t])z[t].
\end{align*}
\]  

(15)

Note that the right-hand-side is completely determined by equation (11)-(14), as a function of \( z[t] \) and is independent of \( N \). We denote \( z[t] \) as the ‘fluid approximation model’ because \( z[t] \) is no longer restricted to take values on the lattice with as the case of the original system state \( Z^N[t] \), and \( z[t] \) evolves in the direction of the expected change of the system state \( Z \). Recall that the set \( Z \) is defined in equation (7), we proceed with the following lemma.

**Lemma 7.** If \( z[0] \in Z \), then \( z[t] \in Z \) for all \( t \geq 0 \).

**Proof:** Since from (13) we have

\[
\begin{align*}
  z[t + 1] - z[t] \bigg|_{z[t]=z} &= Q(z[t])z = \sum_{i,j} z_i[t]q_{ij}(z[t]) \cdot e_{ij}.
\end{align*}
\]

Note that the belief values of a channel can only evolve within the belief states of class of the channel, hence for class 1,

\[
\begin{align*}
  \sum_{i=1}^{2r+1} z_i[t + 1] - \sum_{i=1}^{2r+1} z_i[t] = \bar{I}^T \cdot \sum_{1 \leq i,j \leq 2r+1} z_i[t]q_{ij}(z[t])e_{ij} = \sum_{1 \leq i,j \leq 2r+1} z_i[t]q_{ij}(z[t]) \cdot (1 - 1) = 0,
\end{align*}
\]

where \( \bar{I} \) is a vector with 1 in each element. Similar result holds for class 2. Since \( z[0] \in Z \), we have

\[
\begin{align*}
  \sum_{i=1}^{2r+1} z_i[t] = \gamma_1, \sum_{i=2r+2}^{2(2r+1)} z_i[t] = \gamma_2, \forall t \geq 0.
\end{align*}
\]

Also equation (13)-(15) indicates that \( z_i[t] \geq 0 \) for all \( t \geq 0 \) if \( z[0] \in Z \). Therefore \( z[t] \in Z \) for all \( t \geq 0 \), establishing the lemma.

**Lemma 8.** Given (\( \alpha, \gamma \)), there exists a unique parameter pair (\( \omega^*, \rho^* \)) for the optimal policy \( \phi^* \).

**Proof:** For a single channel \( i \) in class \( k \), consider the policy where the channel activates if its belief value \( \pi_i > b^k \), stays idle when \( \pi_i < b^k \), and activates with probability \( \rho \) when \( \pi_i = b^k \), for some belief value \( b^k \).

From the belief value evolution we can calculate the expected time of activation, denoted by \( A^k(b^k, \rho) \),

\[
\begin{align*}
  A^k(b^k, \rho) = \begin{cases} 
  1 - \frac{\rho b^k}{\rho b^k + (1 - \rho)b^k + (1 - \rho)b^k + (1 - \rho)(h) + (h) + (h - 1) - 1} & \text{if } b^k = b^k_{0,h}, \\
  0 & \text{if } \pi \geq b^k.
\end{cases}
\end{align*}
\]

It is clear from its expression that, given \( b^k, A^k(b^k, \rho) \) is continuous with \( \rho \). Also we have \( A^k(b^k_{0,h}, 0) = A^k(b^k_{0,h+1,1}, 1) \). In addition, some simple algebra reveals that, given \( b^k_{0,h}, A^k(b^k_{0,h}, \rho) \) strictly increases with \( \rho \). Therefore, since \( A^k(b^k_{0,h}, 0) = A^k(b^k_{0,h+1,1}, 1) \), given \( \rho \), \( A^k(b^k, \rho) \) monotonically decreases with \( b^k \in B_k \).

Also, one can observe from the expression that, given \( \rho \), \( \lim_{h \to \infty} A^k(b^k_{0,h}, \rho) = 0 \) and \( A^k(b^k_{0,h}, 1) = 1 \). Hence by appropriately choosing \( b^k \) and \( \rho \), \( A^k(b^k, \rho) \) can achieve any value within [0, 1].

Note that the index value \( W_k(b^k) \) monotonically increases with \( b^k \in B_k, k = 1, 2 \). It follows from the above analysis that, as \( \omega \) increases, under policy \( \phi^*(\omega, 1) \), the fraction of activation time for each user strictly decreases from 1 to 0. Therefore, there exists an unique (\( \omega^*, \rho^* \)) pair, such that the policy \( \phi^*(\omega^*, \rho^*) \) strictly satisfies activation constraint (5).

**Lemma 9.** The vector \( \zeta \) is the unique fixed point of the fluid approximation model, i.e., for all \( z \in Z, Q(z)z = 0 \) if and only if \( z = \zeta \).

**Proof:** The proof follows from a similar line of (22). Note that, under the Optimal Relaxed Policy, \( \zeta \in E[Z^N(\infty)] \) and \( \alpha \) fraction of channels are activated on average. Therefore, in the fluid approximation model, we have \( z[t + 1] - z[t] \bigg|_{z[t]=z} = 0 \), i.e., \( Q(z)\zeta = 0 \).

Now suppose there exists another fixed point \( \zeta_0 \in Z \) such that \( \zeta_0 \neq \zeta \) and \( Q(\zeta_0)\zeta_0 = 0 \). Then \( \zeta_0 \) corresponds to the stationary distribution of the system state under another policy \( \phi(\omega_0, \rho_0) \) with threshold parameter \( \omega_0 \) and randomization factor \( \rho_0 \). Furthermore, under \( \phi(\omega_0, \rho_0) \), the expected fraction of activated channels equals to \( \alpha \). However, this contradicts with Lemma 8 which states that (\( \omega^*, \rho^* \)) is the unique parameter pairs that strictly satisfies the average constraint of activation. Therefore, the fixed point \( \zeta \) is unique.

D. Convergence of the Fluid Limit Model

Define the region \( J_0^* \subseteq Z \) as the set of \( z \in Z \) such that, under the Whittle’s Index Policy defined in Section IV the channel is activated if and only if its index value is no smaller than \( \omega^* \), which is the threshold for the Optimal Relaxed Policy defined in Lemma 7.
This means that, at system state \( z \in J_{\omega^*} \), all channels with index value higher than \( \omega^* \) are scheduled, and the channels with index value smaller than \( \omega^* \) stay idle, while the channels at index value \( \omega^* \) are scheduled with certain randomization. Specifically, \( J_{\omega^*} = \{ z \in \mathbb{Z} : \sum_{i: w_i > \omega^*} z_i < \alpha, \sum_{i: w_i \geq \omega^*} z_i \geq \alpha \} \).

The following lemma characterizes the linearity property of the fluid approximation model in \( J_{\omega^*} \).

**Lemma 10.** (i) The vector \( \tilde{\zeta} \in J_{\omega^*} \).
(ii) The fluid difference equation (15) is linear within the region \( J_{\omega^*} \), i.e., there exist matrix \( Q^* \) and vector \( a^* \) such that

\[
z[t+1] - z[t] = Q^* \cdot z[t] + a^*, \text{ for all } z[t] \in J_{\omega^*}. \quad (16)
\]

**Proof:** (i) The vector \( \tilde{\zeta} \in J_{\omega^*} \) because, if \( z[t] = \tilde{\zeta} \), we have \( \sum_{i: w_i > \omega^*} g_i(z[t]) z_i[t] = \alpha \), where \( g_i(\tilde{\zeta}) z_i[t] \in [0, 1] \) as defined in (11).

(ii) Recall that, at the beginning of the section, we have assumed \( \omega^* = W_1(b_{0,h^*_1}) \) for the belief value \( b_{0,h^*_1} \) of class-1 channel. The difference equation (15) becomes,

\[
z[t+1] - z[t] = \sum_{i,j:i\neq h^*_1} z_{ij} q_{ij}(z) \cdot e_{ij} + \sum_{j} q_{h^*_1 j}(z) \cdot e_{h^*_1 j} + \sum_{j} [g_{h^*_1}(z) q_{h^*_1 j}^0 + (1-g_{h^*_1}(z)) q_{h^*_1 j}^0] \cdot e_{h^*_1 j} = \sum_{i,j:i\neq h^*_1} z_{ij} q_{ij}(z) \cdot e_{ij} + \sum_{j} q_{h^*_1 j}^0 \cdot e_{h^*_1 j} + g_{h^*_1}(z) z_{h^*_1} \sum_{j} [q_{h^*_1 j}^0 - q_{h^*_1 j}^0] \cdot e_{h^*_1 j}. \quad (17)
\]

where the second equality is from (12).

Since the total fraction of users activated is \( \alpha \), we have

\[
g_{h^*_1}(z) z_{h^*_1} = \alpha - \sum_{w_i > \omega^*} z_i, \quad (18)
\]

Substituting the expression (18) back in (17), and noting that \( q_{ij}(z), i \neq h^*_1 \) stays constant for \( z \in J_{\omega^*} \) (since the threshold \( \omega^* \) for activation does not change for \( z \in J_{\omega^*} \)), the linearity property holds.

From Lemma [7] we know that \( z[t] \in \mathbb{Z} \) for all \( t \geq 0 \), i.e.,

\[
\sum_{i=1}^{2r+1} z_i = \gamma_1, \quad \sum_{i=2r+2}^{2(2r+1)} z_i = \gamma_2. \quad (19)
\]

Taking note of Lemma [7] instead of using a \( 2(2r+1) \) dimensional vector \( z \), it suffices to represent the system state by a \( 2 \cdot 2r \) dimension vector \( \tilde{z} \), i.e.,

\[
\tilde{z}[t+1] - \tilde{z}[t] = U^* \cdot \tilde{z}[t] + b^*, \quad (20)
\]

where the matrix \( U^* \) and vector \( b^* \) are obtained after the substitution. The next key lemma captures the eigen structure of matrix \( U^* \).

**Lemma 11.** Each eigen value \( \lambda \) of \( U^* \) satisfies \( |\lambda + 1| < 1 \).

**Proof:** The proof is based on explicit study of matrix \( U^* \) and is given in Appendix [II].

This lemma leads to the local convergence of \( z[t] \).

**Lemma 12.** There exists a positive constant \( \sigma \) such that, if the initial state \( z[0] = x \) of the fluid approximation model is within the \( \sigma \) neighborhood \( \Omega_\sigma(\tilde{\zeta}) \) of \( \tilde{\zeta} \), where \( \Omega_\sigma(\tilde{\zeta}) \subseteq J_{\omega^*} \), then

(i) \( z[t] \in J_{\omega^*} \) for all \( t \geq 0 \);
(ii) \( z[t] \to \tilde{\zeta} \) as \( t \to \infty \).

**Proof:** Similar to \( \tilde{\zeta} \) that corresponds to \( z[t] \), we let vector \( \tilde{\zeta} \) represent the stationary expectation of vector \( \tilde{z}[t] \). Therefore, from Lemma [9],

\[
U^* \cdot \tilde{\zeta} + b^* = 0. \quad (21)
\]

Substituting (21) in equation (20), we have

\[
\tilde{z}[t] - \tilde{\zeta} = (U^* + I)^t (z[0] - \tilde{\zeta}) = (U^* + I)^t (x - \tilde{\zeta}). \quad (22)
\]

Since we have assumed that \( \rho^* \neq 1 \), there exists a \( \sigma_0 \) neighborhood \( \Omega_{\sigma_0}(\tilde{\zeta}) \) with \( \Omega_{\sigma_0}(\tilde{\zeta}) \subseteq J_{\omega^*} \). Correspondingly, there is a neighborhood of \( \tilde{\zeta} \) for which \( \tilde{z}[t] \) evolution is linear and is described by (22). From Lemma [12] each eigen value \( \lambda \) of \( (U^* + I) \) satisfies \( |\lambda| < 1 \). According to the stability theory of linear systems, \( \tilde{z}[t] \) converges to \( \tilde{\zeta} \) if the initial state is close enough to \( \tilde{\zeta} \).

Therefore, there exists a \( \sigma < \sigma_0 \) neighborhood of \( \tilde{\zeta} \) for which if the initial state \( x \in \Omega_\sigma(\tilde{\zeta}) \), \( z[t] \in J_{\omega^*} \) and \( z[t] \to \tilde{\zeta} \) as \( t \to \infty \).
E. Convergence of the system state

The fluid approximation model provides a good estimate for the system state evolution when the number of users is large, captured in the following proposition, which can be viewed as a discrete-time version of Kurtz theorem applied to our problem. The proof is given in Appendix I.

**Proposition 3.** There exists a neighborhood $\Omega_\delta(\tilde{\zeta})$ of $\tilde{\zeta}$ such that if $Z_N^0 = z[0] = x \in \Omega_\delta(\tilde{\zeta})$, then for any $\mu > 0$ and finite time horizon $T$ there exists positive constants $C_1$ and $C_2$ such that

$$P_x \left( \sup_{0 \leq t < T} \| Z_N^t - z[t] \| \geq \mu \right) \leq C_1 \exp(-NC_2),$$

where $\delta < \sigma$, and $P_x$ denotes the probability conditioned on the initial state $Z_N^0 = x$. Furthermore, $C_1$ and $C_2$ are independent of $x$ and $N$.

According to Proposition 3 the system state $Z_N^t$ behaves very close to the fluid approximation model $z[t]$ when the number of users $N$ is large. Since we have shown the convergence of $z[t]$ to $\tilde{\zeta}$ within $\Omega_\sigma(\tilde{\zeta})$ in Lemma 12 we are ready to establish the local convergence of the system state $Z_N^t$ to $\tilde{\zeta}$.

**Lemma 13.** If $Z_N^0 = x \in \Omega_\delta(\tilde{\zeta})$, then for any $\mu > 0$ there exists a time $T_0$ such that for each $T > T_0$, there exist positive constants $s_1$ and $s_2$ with

$$P_x \left( \sup_{T_0 \leq t < T} \| Z_N^t - \tilde{\zeta} \| \geq \mu \right) \leq s_1 \exp(-N s_2).$$

**Proof:** We let $0 < \nu < \mu$. Noting that $\delta < \sigma$, from Lemma 12 we have, given $z[0] = x \in \Omega_\delta(\tilde{\zeta})$, there exists $T_0$ such that for all $t \geq T_0$,

$$\| z[t] - \tilde{\zeta} \| \leq \nu.$$

From Proposition 3 we know that there exist positive constants $s_1$ and $s_2$ such that,

$$P_x \left( \sup_{T_0 \leq t < T} \| Z_N^t - \tilde{\zeta} \| \geq \mu \right) \leq P_x \left( \sup_{T_0 \leq t < T} \| Z_N^t - z[t] \| + \| z[t] - \tilde{\zeta} \| \geq \mu \right) \leq P_x \left( \sup_{T_0 \leq t < T} \| Z_N^t - z[t] \| \geq \mu - \nu \right) \leq P_x \left( \sup_{0 \leq t < T} \| Z_N^t - z[t] \| \geq \mu - \nu \right) \leq s_1 \exp(-N s_2).$$

Hence the lemma holds.

The previous lemma allows us to establish the local convergence result. Let $v : Z \to \mathcal{R}$ be a mapping such that $v(z)$ represents the per-user average throughput under system state $z$. Therefore, $Nv(Z_N^t)$ is the immediate reward at time $t$ and we also have $r(\gamma, \alpha) = v(\tilde{\zeta})$.

For $\ell > 0$, we let $\mu > 0$ be such that for any $x \in Z$, if $\| x - \tilde{\zeta} \| < \mu$, then

$$|v(x) - v(\tilde{\zeta})| < \ell.$$  \hfill (23)

Note that the per-user instantaneous throughput $v(z) \leq 1$ and $T_0$ is defined in Lemma 13. Therefore,

$$\frac{R_N(\gamma, \alpha, x)}{N} - r(\gamma, \alpha) = \frac{1}{N} E \left[ \sum_{t=0}^{T-1} N_m v(Z_N^m[t]) - r(\gamma, \alpha) \right] = \frac{1}{T} \sum_{t=0}^{T-1} E[v(Z_N^[m][t]) - v(\tilde{\zeta})]$$

$$\leq \frac{1}{T} \sum_{t=0}^{T-1} E[v(Z_N^[m][t]) - v(\tilde{\zeta})] + \frac{1}{T} \sum_{t=T_0}^{T-1} E[v(Z_N^[m][t]) - v(\tilde{\zeta})]$$

$$\leq \frac{T_0}{T} + \frac{1}{T} \sum_{t=T_0}^{T-1} E[v(Z_N^[m][t]) - v(\tilde{\zeta})].$$  \hfill (24)

Letting $A_N$ be the event $\{ \sup_{T_0 \leq t < T} \| Z_N^m[t] - \tilde{\zeta} \| \geq \mu \}$, we proceed to bound the second term in (24),

$$\frac{1}{T} \sum_{t=T_0}^{T-1} E[v(Z_N^[m][t]) - v(\tilde{\zeta})] = P_x(A_N) \frac{1}{T} \sum_{t=T_0}^{T-1} E[v(Z_N^[m][t]) - v(\tilde{\zeta})] A_N +$$

$$(1 - P_x(A_N)) \frac{1}{T} \sum_{t=T_0}^{T-1} E[v(Z_N^[m][t]) - v(\tilde{\zeta})] A_N$$

$$\leq P_x(A_N) + (1 - P_x(A_N)) \ell = P_x(A_N) + (1 - \ell) + \ell,$$

where the inequality follows from the fact $v(z) \leq 1$ and the relation (23).

According to Lemma 13 when $x \in \Omega_\delta(\tilde{\zeta})$, we have $\lim_{m \to \infty} P_x(A_N) = 0$, therefore,

$$\lim_{m \to \infty} \left| \frac{R_N(\gamma, \alpha, x)}{N} - r(\gamma, \alpha) \right| \leq \frac{T_0}{T} + \ell.$$
Since $\ell$ can be arbitrarily small, we have
\[
\lim_{m \to \infty} \left| \frac{R^N_{T_m}(\gamma, \alpha, x)}{N_m} - r(\gamma, \alpha) \right| \leq \frac{T_0}{T}.
\]
Hence, taking limit with $T$ in both sides,
\[
\lim_{T \to \infty} \lim_{m \to \infty} \frac{R^N_{T_m}(\gamma, \alpha, x)}{N_m} = r(\gamma, \alpha).
\]
We have thus proved Proposition 1.

**APPENDIX E**

**PROOF OF LEMMA 5**

(i) Here we prove the Markov chain has one unique class by stating that, starting from any state, there exists a possibility to reach a particular state, and hence there is only one class of recurrent state. Without loss of generality, we assume $W_1(b^1_{0,1}) \geq W_2(b^2_{1,1})$.

Case (1). Suppose $\alpha \leq \gamma_1$. Starting from any initial state $Z^N[0]$, the following transition can occur: whenever the channels in class 1 are activated, their states are observed to be in ON state, and whenever channels in class 2 are activated, they are revealed to be in OFF state. Then after a long enough time duration $t_1$, $\alpha$ fraction of channels, which are in class 1, will be in belief state $\pi_1$, and other channels will have stationary belief value $\pi_s$. Hence the system state will be $Z^N[t_1] = [Z^{1,N}[t_1], Z^{2,N}[t_1]]$ (defined in Section V-A) with $Z^{1,N}[t_1] = \alpha$, $Z^{2,N}[t_1] = \gamma_1 - \alpha$, $Z^{2,N}[t_1] = \gamma_2$, and with 0 in all other positions. Case (2). Suppose $\alpha > \gamma_1$. Starting from any initial state $Z^N[0]$, consider the following transition path. Within the first period of time slots, 0 $\leq t \leq t_0$, whenever users in class 1 are activated, they turn out to be in state 1, and whenever users in class 2 are activated, they turn out to be in state 0. Then if $t_0$ is long enough, $Z^{1,N}[t_0]$ is such that $Z_{1,1}^{1,N}[t_0] = \gamma_1$, with zero in all other elements. In the second period, $t_0 \leq t \leq t_1$, whenever users in class 1 are activated, it will remain in state 1, and whenever users in class 2 are activated, it turns out to be in state 1 as well. Then after long enough time until $t_1$, $Z^{1,N}[t_1] = [Z^{1,N}[t_1], Z^{2,N}[t_1]]$ with $Z_{1,1}^{1,N}[t_1] = \gamma_1$, $Z_{1,1}^{2,N}[t_1] = \alpha - \gamma_1$, and $Z_{2,1}^{1,N}[t_1] = 1 - \alpha = \gamma_2 - Z_{1,1}^{2,N}[t_1]$, with zero in all other elements.

(ii) Similar to the proof of Proposition 1, in this part, we drop the suffix $\alpha$ and $\gamma$ in the notation $\xi^\alpha_1$, and we assume, with no loss of generality, $W_2(b^2_{0,2}) < W_1(b^1_{0,1})$. Recall that from the expression (6) of Whittle’s index value that $W_k(\pi) = W_k(b_k^k)$ for $\pi \in B_k$, $\pi \geq b_k^k$, $k = 1, 2$. We first characterize the structure of $\xi$. From the description in Lemma 2 we know that the non-zero elements of $\xi$ are
\[
\xi^1_0 := \xi^1_{0,1} = \xi^1_{0,2} = \cdots = \xi^1_{0,h_1^1} ; \xi^1_{0,\alpha_1} + 1 = (1 - \rho^*) \xi^1_{0,\alpha_1} ; \xi^1_{1,1} = 1 - \sum_{h=1}^{h_1^1} \xi^1_{1,h} ; \xi^2_0 := \xi^2_{0,1} = \xi^2_{0,2} = \cdots = \xi^2_{0,\alpha_2} = \xi^2_{0,\alpha_2}.
\]

We shall proceed to construct a path from the state $Z^N_p$ to an arbitrary neighborhood of $\xi$. For ease of exposition, in the proof we no longer consider the channels as unsplittable entities. Instead, the transition in the each stage (in the following proof) deals with belief state evolution of certain fraction of users. As we shall see, under this assumption, we can construct a transition path of $Z^N[t]$ under the Whittle’s Index Policy, that transits from $Z^N_p$ to the exact value $\xi$. Although the identified path may not be feasible in reality for small value of $N$, but as the number of users $N$ increases, we can find a transition path, which operates each user as unsplittable entities, that is arbitrarily close to this identified path, and thus can ultimately get arbitrarily close to any neighborhood of $\xi$.

Note that when $Z^N[t_1] = Z^N_p$, $Z^N[t_1] = [Z^{1,N}[t_1], Z^{2,N}[t_1]]$, where
\[
Z_{1,1}^{1,N}[t_1] + Z_{s,1}^{1,N}[t_1] = \gamma_1, \quad Z_{1,1}^{2,N}[t_1] + Z_{s,1}^{2,N}[t_1] = \gamma_2.
\]

In the following construction we shall assume that belief values are updated at the end of each slot when the actual channel states are revealed.

**Case (1).** Suppose $h^*_1 \geq h^*_2$ and $W_1(b^1_{0,1}) \geq W_2(b^2_{2,1})$. We shall denote $h' = \max\{t : W_1(b^1_{t,1}) \leq W_2(b^2_{t,2})\}$. In this case, the path is constructed with the stages below, starting from state $Z^N[t_1] = Z^N_p$.

**Stage 1.1.** In the first slot, among the $\alpha$ fraction activated channels, $\alpha - \xi^{1}_{0,\alpha_1 + 1}$ amount remains in ON state, and $\xi^1_{0,\alpha_1 + 1}$ amount turn out in OFF state and are in class 1. Hence the end of this slot, $Z^N = [Z^{1,N}, Z^{2,N}]$
has the following non-zero elements
\[ Z_{0,1}^{1,N} = \zeta_{0, h_t^1 + 1}, \quad Z_{1,1}^{1,N} + Z_{s}^{1,N} = \gamma_1 - \zeta_{0, h_t^1 + 1} \]
\[ Z_{1,1}^{2,N} + Z_{s}^{2,N} = \gamma_2. \]

**Stage 1.2.** In each of the next \( h_1^* \) slots, \( \alpha - \zeta_0^1 \) amount of the activated channels turn out in ON state, and \( \zeta_0^1 \) amount of them turn out to be in OFF state and are in class 1. So at the end of the last slot of this stage, the non-zero elements of the system state \( Z^N = [Z_1^N, Z_2^N] \) satisfies
\[ Z_{0,0}^{1,N} = Z_{0,0}^{1,N} = \cdots = Z_{0,0}^{1,N} = \zeta_0^1, \quad Z_{0,0}^{1,N+1} = \zeta_{0,0}^{h_t^1+1} \]
\[ Z_{1,0}^{1,N} = \zeta_{1,1}^1, \quad Z_{0,0}^{2,N} + Z_{s}^{2,N} = \gamma_2. \]

**Stage 2.** In the next few slots, all activated channels turn out to be in state 1. This stage goes on for \( h_1^1 - h_1^* \) slots, until those channels that reach belief state \( b_{0, h_t^1}^1 \) at the end of stage 1.1 are in belief state \( b_{0, h_t^1}^1 \). Then by the end of the last slot of this stage, the non-zero elements of the system state \( Z^N \) satisfies
\[ Z_{0,0}^{1,N} = \cdots = Z_{0,0}^{1,N} = \zeta_0^1, \quad Z_{0,0}^{1,N+1} = \zeta_{0,0}^{h_t^1+1} \]
\[ Z_{1,0}^{1,N} = \zeta_{1,1}^1, \quad Z_{0,0}^{2,N} + Z_{s}^{2,N} = \gamma_2. \]

**Stage 3.** In each of the following slots, among all channel activated, only those in belief state \( b_{0, h_t^1}^1 \) turn out to be in OFF state. This stage goes on until those channels that transit to belief state \( b_{0, h_t^1}^1 \) in stage 2 reaches belief state \( b_{0, h_t^1 - h_t^2 + 1}^1 \). Hence by the end of the final slot of this stage,
\[ Z_{0,0}^{1,N} = \cdots = Z_{0,0}^{1,N} = \zeta_0^1, \quad Z_{0,0}^{1,N+1} = \zeta_{0,0}^{h_t^1+1} \]
\[ Z_{1,0}^{1,N} = \zeta_{1,1}^1, \quad Z_{0,0}^{2,N} + Z_{s}^{2,N} = \gamma_2. \]

**Stage 4.** In each of the next \( h_0^2 \) slots, among all users activated, those in belief state \( b_{0, h_t^1}^1 \) turn out to be in OFF state, and \( \zeta_0^2 \) amount of activated channels in class 2 turn out in OFF state. Then by the end of the final slot in this stage, the system state will be \( Z^N = \zeta, \) i.e.,
\[ Z_{0,0}^{1,N} = Z_{0,0}^{1,N} = \cdots = Z_{0,0}^{1,N} = \zeta_0^1 \]
\[ Z_{0,0}^{1,N} = \zeta_{0,0}^{h_t^1+1}, \quad Z_{0,1}^{1,N} = \zeta_{0,0}^1, \quad Z_{0,0}^{2,N} = \zeta_{0,0}^1, \quad Z_{0,0}^{2,N} = \zeta_{0,0}^2. \]

**Case (2).** Suppose \( W_1(b_1^2) \geq W_2(b_2^2) \) and \( h_1^* \leq h_2^* \). We shall let \( h_t^1 = \max\{l : W_1(b_1^l) \leq W_2(b_2^2) \} \) and \( d = [h_2^*/h_t^1 + 1] \). Starting from state \( Z^N_{[t]} = Z^N \), the path is constructed with the stages below, where stage 1.1 and 1.2 are the same with the previous case.

**Stage 1.1.** In the first slot, among the \( \alpha \) fraction of activated channels, only \( \zeta_{0, h_t^1 + 1} \) amount turn out in OFF state and they are in class 1. Therefore at the end of this slot, \( Z^N = [Z_1^N, Z_2^N] \) with non-zero elements being
\[ Z_{0,0}^{1,N} = \zeta_{0,0}^{h_t^1+1}, \quad Z_{0,0}^{1,N} = \zeta_{0,0}^1 - \zeta_{0,0}^{h_t^1+1} \]
\[ Z_{1,0}^{1,N} = \zeta_{1,1}^1, \quad Z_{0,0}^{2,N} + Z_{s}^{2,N} = \gamma_2. \]

**Stage 1.2.** In each of the next \( h_1^* \) slots, \( \alpha - \zeta_0^1 \) amount of activated channels are in state ‘1’, and \( \zeta_0^1 \) amount are in OFF state and are in class 1. Hence at the end of the last slot of this stage, the non-zero elements of \( Z^N = [Z_1^N, Z_2^N] \) satisfies
\[ Z_{0,0}^{1,N} = Z_{0,0}^{1,N} = \cdots = Z_{0,0}^{1,N} = \zeta_0^1, \quad Z_{0,0}^{1,N+1} = \zeta_{0,0}^{h_t^1+1} \]
\[ Z_{1,0}^{1,N} = \zeta_{1,1}^1, \quad Z_{0,0}^{2,N} + Z_{s}^{2,N} = \gamma_2. \]

Letting \( t_2 \) be the slot right after stage 1.2, the path proceeds as follows.

**Stage 2.**
(1) From slot \( t_2 \) to slot \( t_2 + h_1^* - h_1^* - 1 \), all activated channels in class 1 turn out to be in state 1. Hence at the end of slot \( t_2 + h_1^* - 1 \), the channels that reach belief state \( b_{0, h_t^1}^1 \) at the end of stage 1.2 are in belief state \( b_{0, h_t^1}^1 \). Next, from slot \( t_2 + h_1^* - h_1^* \) to slot \( t_2 + (d + 1)(h_1^* + 1) - 1 \), among the activated channels in class 1, only those in belief state \( b_{0, h_t^1}^1 \) turn out to be in OFF state. Therefore, at the end of slot \( t_2 + (d + 1)(h_1^* + 1) - 1 \), the system state vector \( Z_1^N \) that correspond to class-1 channels is
\[ Z_{0,0}^{1,N} = Z_{0,0}^{1,N} = \cdots = Z_{0,0}^{1,N} = \zeta_0^1 \]
\[ Z_{1,0}^{1,N} = \zeta_{0,0}^1, \quad Z_{1,1}^{1,N} = \zeta_{1,1}^1. \]

(2) In the meanwhile, from slot \( t_2 + (d + 1)(h_1^* + 1) - h_2^* - 1 \) to slot \( t_2 + (d + 1)(h_1^* + 1) - 1 \), among the activated channels in class 2, \( \zeta_0^2 \) amount turn out to be in OFF state. Hence by the end of slot \( t_2 + (d + 1)(h_1^* + 1) - 1 \), the vector \( Z_1^N \) that correspond to class-2 channels is
\[ Z_{0,0}^{2,N} = Z_{0,0}^{2,N} = \cdots = Z_{0,0}^{2,N} = Z_{0, h_t^2} = \zeta_0, \quad Z_{1,0}^{2,N} = \zeta_{1,0}, \quad Z_{1,1}^{2,N} = \zeta_{1,1}. \]

Therefore, at the end of slot \( t_2 + (d + 1)(h_1^* + 1) - 1 \), \( Z^N = \zeta \).

**APPENDIX F**

**PROOF OF LEMMA 13**

The proof is a discrete-time version of the proof of Theorem 6.89 from [10]. We first present a lemma which is an extension of Lemma 13.

**Lemma 14.** There is a neighborhood \( \Omega_{d}(\zeta_0^f) \) of \( \zeta_0^f \), with \( \delta < \delta \), for which if \( Z^N[0] = x \in \Omega_{d}(\zeta_0^f) \), then
for any $\mu > 0$ and time $T$, there exist positive constants $\rho_1$ and $\rho_2$ with,

$$P_x \left( \sup_{0 \leq t \leq T} \| Z^N[t] - \xi_1^\alpha \| \geq \mu \right) \leq \rho_1 \exp(-N \rho_2)$$

where $\rho_1$ and $\rho_2$ are independent of $x$ and $N$.

Proof: Note that we have established, in Lemma [12] the local convergence of the fluid approximation model $z[t]$ in a neighborhood $\Omega_\delta(\xi_1^\alpha)$. We let $\nu < \mu$ and let $\vartheta < \delta$ (recall that $\delta$ is defined in proposition [3] with $\delta < \sigma$) be such that if $z[0] \in \Omega_\vartheta(\xi_1^\alpha)$, then

$$\| z[t] - \xi_1^\alpha \| \leq \nu, \quad \forall t \geq 0.$$  

From Proposition [3] there exist positive constants $\rho_1$ and $\rho_2$ with,

$$P_x \left( \sup_{0 \leq t \leq T} \| Z^N[t] - \xi_1^\alpha \| \geq \mu \right) \leq \rho_1 \exp(-N \rho_2),$$

which proves the lemma.

We let $\vartheta < \vartheta$ be such that if $z[0] \in \Omega_\vartheta(\xi_1^\alpha)$, then $z[t] \in \Omega_\vartheta(\xi_1^\alpha)$ for $t \geq 0$.

We let $\vartheta^N_n$, $n = 0, 1, \cdots$ be the time slots of consecutive hitting times into the neighborhood $\Omega_\vartheta(\xi_1^\alpha)$ from outside of the neighborhood when the total number of users is $N$. Similarly, we let $\vartheta^N_{n+1}$, $n = 0, 1, \cdots$ denote the time slots of exiting the neighborhood $\Omega_\vartheta(\xi_1^\alpha)$ from inside of the neighborhood, when the total number of users is $N$. Hence $y_n = Z^N[e^N_n]$, $n = 0, 1, \cdots$ evolves as a Markov chain. In steady state,

$$P\left( Z^N[\infty] \notin \Omega_\vartheta(\xi_1^\alpha) \right) \leq \frac{E[\vartheta^N_{2n+2} - \vartheta^N_{2n+1}]}{E[\vartheta^N_{2n+2} - \vartheta^N_{2n+1}]} \leq \frac{E[\vartheta^N_{2n+2} - \vartheta^N_{2n+1}]}{E[\vartheta^N_{2n+2} - \vartheta^N_{2n+1}]} + \frac{E[\vartheta^N_{2n+2} - \vartheta^N_{2n}]}{E[\vartheta^N_{2n+2} - \vartheta^N_{2n}]}.$$  

(25)

We let $T_e(N)$ denote the random variable $\vartheta^N_{2n+1} - \vartheta^N_{2n}$. For any constant $K > 0$, we have

$$E[T_e(N)] = \sum_{t=1}^\infty t \cdot P(T_e(N) = t) \geq 2K \cdot P(T_e(N) \geq 2K)$$

$$= 2K \cdot P_{x^N}[\vartheta^N_{2n+1}] \left( \sup_{0 \leq t \leq \vartheta^N_{2n+1} + 2K} \| Z^N[t] - \xi_1^\alpha \| \leq \mu \right).$$  

(26)

Note that

$$P_{x^N}[\vartheta^N_{2n+1}] \left( \sup_{0 \leq t \leq \vartheta^N_{2n+1} + 2K} \| Z^N[t] - \xi_1^\alpha \| > \mu \right)$$

$$= \sum_{z \in \Omega_\vartheta(\xi_1^\alpha)} P(\vartheta^N = z) P_{x^N}[\vartheta^N[t] - \xi_1^\alpha > \mu] \leq \rho_1 \exp(-N \rho_2).$$  

(27)

Since $\vartheta < \vartheta$, from Lemma [14] there exist positive constants $\vartheta_1$ and $\vartheta_2$ such that for any $z \in \Omega_\vartheta(\xi_1^\alpha)$,

$$P \left( \sup_{0 \leq t \leq 2K} \| Z^N[t] - \xi_1^\alpha \| > \epsilon \right) \leq \vartheta_1 \exp(-\vartheta_2 N).$$  

(28)

Substitute (28) in (27) we have

$$P_{x^N}[\vartheta^N_{2n+1}] \left( \sup_{0 \leq t \leq \vartheta^N_{2n+1} + 2K} \| Z^N[t] - \xi_1^\alpha \| > \epsilon \right)$$

$$\leq \vartheta_1 \exp(-\vartheta_2 N).$$

Therefore, $P_{x^N}[\vartheta^N_{2n+1}] \left( \sup_{0 \leq t \leq \vartheta^N_{2n+1} + 2K} \| Z^N[t] - \xi_1^\alpha \| > \epsilon \right) \rightarrow 1$ as $m \rightarrow \infty$. From (26), if $m$ is large enough, we have

$$E[T_e(N_m)] \geq K.$$  

Since $K$ can be arbitrarily large, $\lim_{m \rightarrow \infty} E[T_e(N_m)] = \infty$, i.e., $\lim_{m \rightarrow \infty} E[\vartheta^N_{2n+1} - \vartheta^N_{2n}] = \infty$. Since from Assumption $\Psi$ we know $E[\vartheta^N_{2n+1} - \vartheta^N_{2n}] \leq M_\epsilon$, thus from equation (25),

$$\lim_{m \rightarrow \infty} P(Z^N_{\infty} \notin \Omega_\vartheta(\xi_1^\alpha)) = 0,$$

which concludes the proof.

APPENDIX G

PROOF OF PROPOSITION [2]

For any $\ell > 0$, let $\epsilon > 0$ be such that for $x \in Z$, if $|x - \xi_1^\alpha| < \epsilon$, then $|v(x) - r(\gamma, \alpha)| < \ell$.

Consider fixed $N_m$, for $\forall \ell > 0$ denote event $E_{N_m} = \{ Z^N_{\infty} \in \Omega_\vartheta(\xi_1^\alpha) \}$, then

$$\frac{|R_{x^N}^{N_m}(\gamma, \alpha) - r(\gamma, \alpha)|}{N_m} \leq E\left[ |v(Z^N_{\infty}) - v(\xi_1^\alpha)| \right]$$

$$= P(E_{N_m}) E\left[ |v(Z^N_{\infty}) - v(\xi_1^\alpha)| \right] E_{N_m}$$

$$+ P(\overline{E_{N_m}}) E\left[ |v(Z^N_{\infty}) - v(\xi_1^\alpha)| \right] E_{N_m}$$

$$\leq P(Z^N_{\infty} \notin \Omega_\vartheta(\xi_1^\alpha)) \cdot \ell + P(Z^N_{\infty} \notin \Omega_\vartheta(\xi_1^\alpha)).$$  

(29)
Lemma 6 to (29) we have
\[
\lim_{m \to \infty} \frac{P_{N_k}(\gamma, \alpha)}{N_m} - r(\gamma, \alpha) \leq \lim_{m \to \infty} P(Z^{N_m}[\infty] \in \Omega(\zeta_{\gamma}^m)) \cdot \ell
\]
\[
= \ell.
\]
Since \( \ell \) can be arbitrary,
\[
\lim_{m \to \infty} \frac{P_{N_k}(\gamma, \alpha)}{N_m} = r(\gamma, \alpha),
\]
which proves the proposition.

**APPENDIX H**

**PROOF OF LEMMA 11**

After some algebra, the matrix \( U^* \) takes the form
\[
U^* = \begin{bmatrix} \bar{Q}^1(z) & B \\ 0 & \bar{Q}^2(z) \end{bmatrix},
\]
where matrix \( B \) is expressed as
\[
B = \begin{bmatrix} 0 & \cdots & 0 & b_{0,h_1}^1 & b_{0,h_1}^1 - 1 & \cdots & b_{0,h_1}^1 - 1 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 0 & -b_{0,h_1}^1 & -b_{0,h_1}^1 & \cdots & -b_{0,h_1}^1 \end{bmatrix}
\]
in which only the first, last and \( h_1 + 1 \) \( \text{th} \) row have non-zero elements, and for each row, non-zero terms start at the \( h_2 \text{th} \) element.

The matrices \( \bar{Q}^1(z) \) and \( \bar{Q}^1(z) \) are expressed in (30-31).

We need the following lemma to proceed.

**Lemma 15.** For any \( 0 < l \in \mathbb{Z}^+ \),
\[
(1 - p_1) + b_{l+1}^1 > (l - 1)(b_{0,l+1}^1 - b_{0,l}^1).
\]

**Proof:** The proof is moved to Appendix [33].

With this lemma, we proceed to characterize the eigen values of matrix \( U^* \), which are given by the solution to equation \( \det(U^* - \lambda I) = 0 \), where
\[
\det(U^* - \lambda I) = \det \begin{bmatrix} \bar{Q}^1(z) - \lambda I & B \\ \bar{Q}^2(z) - \lambda I & 0 \end{bmatrix} = \det \begin{bmatrix} \bar{Q}^1(z) - \lambda I & \bar{Q}^2(z) - \lambda I \end{bmatrix},
\]
where the second equality is from the property of block matrices. Therefore, we have
\[
\det(U^* - \lambda I) = \det(\bar{Q}^1(z) - \lambda I) \det(\bar{Q}^2(z) - \lambda I).
\]
(1) We first study the characteristic polynomial \( \det(\bar{Q}^1(z) - \lambda I) \). After some algebra we have
\[
\det(\bar{Q}^1(z) - \lambda I) = (1 + \lambda)^{2r - h_1} \left[ (\lambda + (1 - p_1) + b_{0,h_1}^1)(1 + \lambda)^{h_1 - 1} - (b_{0,h_1}^1 - b_{0,h_1}^1)(1 + (1 + \lambda) + (1 + \lambda)^2 + \cdots + (1 + \lambda)^{h_1 - 2}) \right]
\]
\[
= (1 + \lambda)^{2r - h_1} \chi_1(\lambda),
\]
where
\[
\chi_1(\lambda) = [\lambda + (1 - p_1) + b_{0,h_1}^1](1 + \lambda)^{h_1 - 1} - (b_{0,h_1}^1 - b_{0,h_1}^1)(1 + (1 + \lambda) + \cdots + (1 + \lambda)^{h_1 - 2}).
\]

The matrix \( \bar{Q}^1(z) \) hence has eigen value \(-1\) of multiplicity \( 2r - h_1 \). Let \( \lambda \) be any other eigen value of \( \bar{Q}^1(z) \), we hence have, i.e., \( \chi_1(\lambda) = 0 \), i.e.,
\[
[\lambda + (1 - p_1) + b_{0,h_1}^1](1 + \lambda)^{h_1 - 1} - (b_{0,h_1}^1 - b_{0,h_1}^1)(1 + (1 + \lambda) + \cdots + (1 + \lambda)^{h_1 - 2}).
\]

We proceed to show that \(|\lambda + 1| < 1\). We prove this by contradiction, suppose \( \lambda \) is such that \(|\lambda + 1| \geq 1\).

Then taking modulus of the left hand side equation (33) we have
\[
0 = |(\lambda + (1 - p_1) + b_{0,h_1}^1)(1 + \lambda)^{h_1 - 1} - (b_{0,h_1}^1 - b_{0,h_1}^1)(1 + (1 + \lambda) + \cdots + (1 + \lambda)^{h_1 - 2})| \geq |(\lambda + 1) - (p_1 - b_{0,h_1}^1)| \cdot |1 + \lambda|^{h_1 - 1}
\]
\[
\geq (1 - p_1 + b_{0,h_1}^1)|1 + \lambda|^{h_1 - 1},
\]
where the first equality is from triangle inequality. Applying Lemma [15] we have,
\[
(1 - p_1 + b_{0,h_1}^1)|1 + \lambda|^{h_1 - 1} > (h_1 - 1)(b_{0,h_1}^1 - b_{0,h_1}^1)|1 + \lambda|^{h_1 - 1}
\]
\[
> (b_{0,h_1}^1 - b_{0,h_1}^1)(1 + \lambda) + \cdots + (1 + \lambda)^{h_1 - 2}
\]
\[
\geq (b_{0,h_1}^1 + 1)(1 + \lambda)^{h_1 - 2}.
\]

(2) We then study the characteristic polynomial
\[
det(Q^2(z) - \lambda I). \text{ We derive that}
\]
\[
det(Q^2(z) - \lambda I) = (1 + \lambda)^{2r-h} \left[(1-p_2) + (1-b_{0,hz}^2)\lambda\right]
\cdot \left[1 + (1 + \lambda) + \cdots + (1 + \lambda)^{h-3}\right]
+ (1 + \lambda)^{h-2} \left[[(1-p_2) + \lambda](2 + \lambda) + b_{0,hz}^2\right]
\triangleq (1 + \lambda)^{2r-h} \cdot \chi_2(\lambda), \tag{35}
\]
where
\[
\chi_2(\lambda) = 
\left[(1-p_2)+(1-b_{0,hz}^2)\lambda\right]\left[1+(1+\lambda)+\cdots+(1+\lambda)^{h-3}\right]
+ (1 + \lambda)^{h-2} \left[[(1-p_2) + \lambda](2 + \lambda) + b_{0,hz}^2\right].
\]

Consider
\[
\lambda \cdot \chi_2(\lambda)
= [(1-p_2)+(1-b_{0,hz}^2)\lambda] \lambda \left[1+(1+\lambda)+\cdots+(1+\lambda)^{h-3}\right]
+ (1 + \lambda)^{h-2} \left[[(1-p_2) + \lambda](2 + \lambda) + b_{0,hz}^2\right]
= [(1-p_2)+(1-b_{0,hz}^2)\lambda] \lambda \left[1+(1+\lambda)\right] + \cdots
+ (1 + \lambda)^{h-3} \left[[(1-p_2) + \lambda](2 + \lambda) + b_{0,hz}^2\right]
= [(1-p_2)+(1-b_{0,hz}^2)\lambda] \lambda \left[1+(1+\lambda)^{h-2} - 1\right]
+ (1 + \lambda)^{h-2} \left[[(1-p_2) + \lambda](2 + \lambda) + b_{0,hz}^2\right]
= - \left[(1-p_2)+(1-b_{0,hz}^2)\lambda\right] + (1 + \lambda)^{h-2}\left[\lambda[(1-p_2)
+ \lambda](2 + \lambda) + b_{0,hz}^2\right]
= - \left[(1-p_2)+(1-b_{0,hz}^2)\lambda\right] + (1 + \lambda)^{h-2}\left[
[(1-p_2) + (1-b_{0,hz}^2)\lambda](2 + \lambda) + (\lambda + 1)^2\right]
= - \left[(1-p_2)+(1-b_{0,hz}^2)\lambda\right] + (1 + \lambda)^{h-2}\left[
[(1-p_2) + (1-b_{0,hz}^2)\lambda](2 + \lambda) + (\lambda + 1)^2\right]
= - \left[(1-p_2)+(1-b_{0,hz}^2)\lambda\right] + (1 + \lambda)^{h-2}\left[
[(1-p_2) + (1-b_{0,hz}^2)\lambda](2 + \lambda) + (\lambda + 1)^2\right]
= \left[(1-p_2)+(1-b_{0,hz}^2)\lambda\right] + (1 + \lambda)^{h-2}\left[(1-p_2) + (1-b_{0,hz}^2)\lambda\right]
= \left[(1-p_2)+(1-b_{0,hz}^2)\lambda\right] + (1 + \lambda)^{h-2}\left[(1-p_2) + (1-b_{0,hz}^2)\lambda\right].
\]

\[
\tilde{Q}^1(z) = \begin{bmatrix}
-1 & 0 & \cdots & 0 & b_{0,hz}^1 - b_{0,hz}^1 & b_{0,hz}^1 - b_{0,hz}^1 + 2 & \cdots & b_{0,hz}^1 - p_1 \\
1 & -1 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\cdots & 1 & -1 & \cdots & \cdots & \cdots & \cdots & \cdots \\
-1 & \cdots & -1 & -1 & \cdots & \cdots & \cdots & \cdots \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\end{bmatrix} \tag{30}
\]
\[
\tilde{Q}^2(z) = \begin{bmatrix}
-1 & 0 & \cdots & 0 & 1 - b_{0,hz}^2 & 1 - b_{0,hz}^2 + 1 & \cdots & 1 - p_2 \\
1 & -1 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\cdots & 1 & -1 & \cdots & \cdots & \cdots & \cdots & \cdots \\
-1 & \cdots & -1 & -1 & \cdots & \cdots & \cdots & \cdots \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\end{bmatrix} \tag{31}
\]
It is clear from equation (35) that matrix $\tilde{Q}^2(z)$ has eigen value $-1$ with multiplicity $2\tau - h_2^*$. Let $\lambda$ be any eigen value of $\tilde{Q}^2(z)$, we first show the following lemma.

**Lemma 16.** Let $\lambda$ be any eigen value of $\tilde{Q}^2(z)$, then $-2 < \text{Re}(\lambda) < 0$.

**Proof:** 1) Suppose $\tilde{Q}^2(z)$ has an eigen value of 0, then, from (35), $\chi(0) = 0$. However,

$$\chi(0) = (1-p_2)(h_2^*-2)+2(1-p_2)+b_0^2$$

$$= h_2^*(1-p_2)+b_0^2 
eq 0,$$

leading to a contradiction. Hence $\tilde{Q}^2(z)$ does not have 0 eigen value.

2) Suppose the equation $\chi(\lambda) = 0$ has a root $\lambda^* = a+bi$ with $a > 0$, or $a \leq -2$, or being purely imaginary with $a = 0, b \neq 0$. Hence from equation (36),

$$(1-p_2)+(1-b^2_{0,h_2})\lambda^*=(1+\lambda^*)h_2^*(1-p_2+\lambda^*). \quad (37)$$

Consider the modulus of the right hand side,

$$|\lambda^* h_2^* | \cdot |1-p_2 + a + bi|$$

$$>|1 - p_2 + a + bi|$$

$$>|1 - p_2 + (1-b^2_{0,h_2})(a + bi)|$$

$$=|1 - p_2 + (1-b^2_{0,h_2})\lambda^*|.$$

The above expression contradicts the previous equation (37).

From 1) and 2) we conclude that $\chi(\lambda) = 0$ can only have solution with real part within $(-2, 0)$. Therefore all eigen values of matrix $\tilde{Q}^2(z)$ have real part within $(-2, 0)$.

We proceed to show that each eigen value $\lambda$ of $\tilde{Q}^2(z)$ needs to satisfy $|\lambda + 1| < 1$.

Suppose the equation $\chi(\lambda) = 0$ has a root $\lambda$ with $|\lambda + 1| \geq 1$, then from equation (36),

$$(1-p_2)+(1-b^2_{0,h_2})\lambda=(1+\lambda)h_2^*(1-p_2+\lambda). \quad (38)$$

We let $1 + \lambda = x + yi$ where $x, y \in \mathbb{R}$. From the previous lemma we know that $|x| < 1$. Some derivation shows that

$$|\lambda^* h_2^* | \cdot |1-p_2 + a + bi|$$

$$>|1 - p_2 + a + bi|$$

$$>|1 - p_2 + (1-b^2_{0,h_2})(a + bi)|$$

$$=|1 - p_2 + (1-b^2_{0,h_2})\lambda^*|.$$

The above expression contradicts equation (37).

Hence it can not be $|\lambda + 1| \geq 1$. Therefore, each eigen value $\lambda$ of $U^*$ satisfies $|\lambda + 1| < 1$, which concludes the proof.

**APPENDIX I**

**PROOF OF PROPOSITION 5**

Consider the random variable $Z^N[t + 1]$ given $Z^N[t] = z$, i.e.,

$$Z^N[t + 1] = Z^N[t] + \sum_{i,j=1}^{N^2} \eta_{ij}^h(z) \cdot e_{ij} \quad (39)$$

where $\eta_{ij}^h(z)$ is an indicator function representing whether the belief value of the $i^{th}$ user transits from belief value $\beta_i$ to belief value $\beta_j$ at the next time slot. Note that, given $Z^N[t] = z$, the scheduling action for users in belief state $\beta_i$ is independent of $N$ because the scheduling decision only depends on the belief state distribution $z$. As $N$ increases and $z$ stays unchanged, more users are in belief state $\beta_i$ and the contribution of each channel to the transition of $Z^N$ scales down with $N$. From the law of large numbers, if the number of users scales up while $z_i$ is kept the same, we have

$$\frac{1}{N} \sum_{h=1}^{Nz_i} \eta_{ij}^h(z) \rightarrow Nz_i \quad (40)$$

almost surely, where $q_{ij}(z)$ is defined in (12).

**Lemma 17.** There exists a neighborhood $\Omega_{\epsilon}(\tilde{\Omega})$ of $\tilde{\Omega}$ such that, for any $\mu > 0$, if $Z^N[t] = z \in \Omega_{\epsilon}(\tilde{\Omega})$, there exists a function $f(\mu)$ for which $Z^N[t + 1]$ satisfies

$$P \left( \left\| Z^N[t + 1] - (I + Q(z)) z \right\| \geq \mu \right) \leq 4 \exp(-N \cdot f(\mu)),$$
where \( f(\mu) \) is independent of \( z \) and \( N \).

Proof: Let \( \vec{I}_i \) be a vector with 1 at the \( i^{th} \) position and 0 in all other elements. From \((39)\),

\[
Z^N[t+1] - (I + Q(z))z
= \sum_{i,j=1}^{2(2\tau+1)} \frac{\sum_{h=1}^{Nz_i} \eta_{ij}^h(z)}{N} \cdot e_{ij} - \eta_i(z)z
= \sum_{i,j=1}^{2(2\tau+1)} \frac{\sum_{h=1}^{Nz_i} \eta_{ij}^h(z)}{N} \cdot e_{ij} - \sum_{i,j=1}^{2(2\tau+1)} z_iq_{ij}(z) \cdot e_{ij}
= \sum_{i,j=1}^{2(2\tau+1)} \frac{\sum_{h=1}^{Nz_i} \eta_{ij}^h(z)}{N} \cdot (\vec{I}_j - \vec{I}_i)
\]

Note that

\[
\sum_{i,j=1}^{2(2\tau+1)} \frac{\sum_{h=1}^{Nz_i} \eta_{ij}^h(z)}{N} \cdot \vec{I}_i - \sum_{i,j=1}^{2(2\tau+1)} z_iq_{ij}(z) \cdot \vec{I}_i
= \sum_{i=1}^{2(2\tau+1)} \frac{\sum_{h=1}^{Nz_i} \eta_{ij}^h(z)}{N} \cdot \vec{I}_i
- \sum_{i=1}^{2(2\tau+1)} z_i \sum_{j=1}^{2(2\tau+1)} q_{ij}(z) \cdot \vec{I}_i
= \sum_{i=1}^{2(2\tau+1)} z_i \vec{I}_i - \sum_{i=1}^{2(2\tau+1)} z_i \vec{I}_i
= 0,
\]

where the second equality holds because \( \sum_{j=1}^{2(2\tau+1)} \eta_{ij}^h(z) = 1 \) for all \( h \), and \( \sum_{j=1}^{2(2\tau+1)} q_{ij}(z) = 1 \)
for all \( i \).

Therefore

\[
Z^N[t+1] - (I + Q(z))z
= \frac{\sum_{h=1}^{Nz_i} \eta_{ij}^h(z)}{N} \cdot \vec{I}_j - \frac{\sum_{h=1}^{Nz_i} \eta_{ij}^h(z)}{N} \cdot \vec{I}_i
= \sum_{i,j=1}^{2(2\tau+1)} \frac{\sum_{h=1}^{Nz_i} \eta_{ij}^h(z)}{N} \cdot (\vec{I}_j - \vec{I}_i)
\]

is no randomness associated with its belief transition, i.e., for them \( \eta_{ij}^h(z) = q_{ij}(z) \in \{0,1\} \). Therefore the randomness is only associated with the channels which are activated, i.e., those with index value no smaller than \( \omega^* \). Hence, \((40)\) becomes

\[
Z^N[t+1] - (I + Q(z))z
= \sum_{j \in \Theta} \sum_{i \in \Pi_j(z)} \frac{\sum_{h=1}^{Nz_i} (\eta_{ij}^h(z) - q_{ij}(z))}{N} \cdot \vec{I}_j,
\]

where the summation \( \sum_{h=1}^{Nz_i}(\cdot) \) is over all the channels in belief state \( \beta_i \) that are activated, and \( \Pi_j(z) \) is the set of belief values in which channels are scheduled within the class that corresponds to belief \( j \in \Theta \), i.e.,

\[
\Pi_j(z) := \begin{cases} 
\{1 \leq i \leq 2\tau + 1 : g_i(z) > 0\} & \text{if } j = 1, 2\tau + 1, \\
\{2\tau + 1 + 1 \leq i \leq 2(2\tau + 1) : g_i(z) > 0\} & \text{if } j = 2\tau + 2, 2(2\tau + 1).
\end{cases}
\]

We hence have

\[
P\left(\left\| Z^N[t+1] - (I + Q(z))z \right\| > \mu \right) Z^N[t]=z
\]

\[
= P\left( \left\| \sum_{j \in \Theta} \sum_{i \in \Pi_j(z)} \frac{\sum_{h=1}^{Nz_i} (\eta_{ij}^h(z) - q_{ij}(z))}{N} \cdot \vec{I}_j \right\| > \mu \right)
\leq \sum_{j \in \Theta} P\left( \left\| \sum_{i \in \Pi_j(z)} \sum_{h=1}^{Nz_i} \frac{(\eta_{ij}^h(z) - q_{ij}(z))}{N} \cdot \vec{I}_j \right\| > \mu \right),
\]

where the last inequality holds because \( |\Theta| = 4 \) as well as the union bound. Specifically, the union bound holds since

\[
\{ \left\| \sum_{j \in \Theta} \sum_{i \in \Pi_j(z)} \frac{\sum_{h=1}^{Nz_i} (\eta_{ij}^h(z) - q_{ij}(z))}{N} \cdot \vec{I}_j \right\| > \mu \}
\leq \bigcup_{j \in \Theta} \left\{ \left\| \sum_{i \in \Pi_j(z)} \sum_{h=1}^{Nz_i} \frac{(\eta_{ij}^h(z) - q_{ij}(z))}{N} \cdot \vec{I}_j \right\| > \mu \right\}
\]

Note that, for each \( j \in \Theta \), the random variables \( \eta_{ij}^h(z), h = 1, \cdots, g_i(z)Nz_i \) are independent. From an extension of Chebycheff's inequality (See Exercise 1.8 in \((39)\) we have that, for each \( j \in \Theta \), there exists a positive continuous function \( f_j(\mu) \), which does not depend on \( z \) and \( N \), with

\[
P\left( \left\| \sum_{i \in \Pi_j(z)} \sum_{h=1}^{Nz_i} \frac{(\eta_{ij}^h(z) - q_{ij}(z))}{N} \right\| > \frac{\mu}{4} \right)
< \exp \left( -f_j(\mu) \sum_{i \in \Pi_j(z)} g_i(z)Nz_i \right).
\]
Let $\alpha_j$ be the fraction of channels activated, under the steady state of Optimal Relaxed Policy, in the class corresponding to belief value $\beta_j$, i.e.,

$$\alpha_j = \begin{cases} 
\sum_{i=1}^{2^{\tau+1}} g_i(\zeta) \zeta_i & \text{if } j \in \{1, 2^{\tau+1}\}, \\
\sum_{i=2^{\tau+1}}^{2^{2\tau+2}} g_i(\zeta) \zeta_i & \text{if } j \in \{2^{\tau+1}+1, 2^{2\tau+2}\}.
\end{cases}$$  \hspace{1cm} (43)

For any $0 < \ell < \min\{\alpha_j, j \in \Theta\}$, there exists a neighborhood $\Omega_{\varepsilon}(\zeta)$ such that for all $z \in \Omega_{\varepsilon}(\zeta)$,

$$\sum_{i \in \Pi_j(z)} g_i(z) z_i \geq \alpha_j - \ell, \quad j \in \Theta,$$  \hspace{1cm} (44)

which essentially means, under system state $z \in \Omega_{\varepsilon}(\zeta)$, the fraction of activated channels in each class will stay close to the case when system state is actually $\zeta$. Let $f(\mu) = \min\{f_j(\mu)(\alpha_j - \ell), j \in \Theta\}$, then from (41-44),

$$P\left(\|Z^N[t+1] - (I + Q(z))[z]\| \geq \mu\|Z^N[t] = z\right)$$

$$\leq \sum_{j \in \Theta} \left\{ \sum_{i \in \Pi_j} \sum_{h=1}^{N} \frac{\eta_{ij}(z) - \eta_{ij}(\bar{z})}{\sqrt{N}} \right\} \geq \mu \right)$$

$$\leq 4\exp(-N \cdot f(\mu)).$$

It is clear from the proof that $f(\mu)$ does not depend on $z$ or $N$. The lemma thus holds.

**Lemma 18.** There exists a neighborhood $\Omega_{\varepsilon}(\zeta)$ of $\zeta$ such that, for any $\mu > 0$, if $Z^N[0] = x \in \Omega_{\varepsilon}(\zeta)$, for any $t \geq 1$, there exist positive constant $c_1^\prime$ and $c_2^\prime$ with

$$P_x\left(\|Z^N[t] - z[t]\| \geq \mu\right) \leq c_1^\prime \cdot \exp(-N \cdot c_2^\prime),$$

where $c_1^\prime$ and $c_2^\prime$ is independent of $x$ and $N$.

**Proof:** We let $\nu < \mu$. From Lemma 17 there exists $\varepsilon$ such that if $z \in \Omega_{\varepsilon}(\zeta)$

$$P\left(\|Z^N[t+1] - (I + Q(z))[z]\| \geq \mu\|Z^N[t] = z\right)$$

$$\leq 4\exp(-f(\mu) \cdot N).$$  \hspace{1cm} (45)

We let $\rho < \varepsilon$ be such that

$$\| (Q(x) + I)x - (Q(y) + I)y \| \leq \nu$$  \hspace{1cm} (46)

for all $x, y \in \mathbb{Z}$ with $\|x - y\| \leq \rho$. Recall that $\sigma$ is defined in Lemma 12. We let $\delta < \min\{\varepsilon, \rho\}$ be such that, if $z[0] \in \Omega_{\delta}(\zeta)$, $z[t] \in \Omega_{\varepsilon-\rho}(\zeta)$ for all $t \geq 1$. We proceed to prove this statement by induction.

For $t = 1$, if $x \in \Omega_{\delta}(\zeta)$, from inequality (45), there exists $f(\mu)$,

$$P_x\left(\|Z^N[1] - z[1]\| \geq \mu\right)$$

$$= P_x\left(\|Z^N[1] - (I + Q(x))[z]\| \geq \mu\right)$$

$$\leq 4\exp(-f(\mu) \cdot N).$$  \hspace{1cm} (47)

Letting $c_1^1 = 4$ and $c_2^1 = f(\mu)$, the statement holds when $t = 1$.

Suppose the statement is true at $t \geq 1$, then there exist $d_1^t$ and $d_2^t$, which correspond to $\rho$, for which,

$$P_x\left(\|Z^N[t+1] - z[t+1]\| \geq \mu\right) \leq d_1^t \exp(-N \cdot c_2^t),$$

$$\cdot P_x\left(\|\|Z^N[t+1] - z[t+1]\| \geq \mu\|Z^N[t] - z[t]\| \geq \mu\right)$$

$$\cdot P_x\left(\|\|Z^N[t+1] - z[t+1]\| \geq \mu\|Z^N[t] - z[t]\| < \rho\right)$$

$$\leq d_1^t \exp(-N \cdot c_2^t),$$

$$\cdot P_x\left(\|\|Z^N[t+1] - z[t+1]\| \geq \mu\|Z^N[t] - z[t]\| < \rho\right).$$  \hspace{1cm} (48)

Now consider the second term in (48),

$$P_x\left(\|Z^N[t+1] - z[t+1]\| \geq \mu\|\|Z^N[t] - z[t]\| < \rho\right)$$

$$= P_x\left(\|\|Z^N[t+1] - (I + Q(Z^N[t]))Z^N[t] + (I + Q(Z^N[t]))\| \geq \mu\|Z^N[t] - z[t]\| < \rho\right)$$

$$\leq \exp(-N \cdot c_2^t),$$

$$\cdot P_x\left(\|\|Z^N[t+1] - (I + Q(Z^N[t]))Z^N[t]\| \geq \mu\|Z^N[t] - z[t]\| < \rho\right)$$

$$\leq \exp(-N \cdot c_2^t),$$

$$\cdot P_x\left(\|\|Z^N[t+1] - (I + Q(Z^N[t]))Z^N[t]\| \geq \mu\|Z^N[t] - z[t]\| < \rho\right).$$

where the first inequality follows from triangle inequality, and the second inequality is from relationship (46).

Because $z[t] \in \Omega_{\varepsilon-\mu}(\zeta)$, we have $\Omega_{\rho}(z[t]) \subseteq \Omega_{\varepsilon}(\zeta)$. From inequality (45), we have

$$P_x\left(\|Z^N[t+1] - (I + Q(z))[z]\| \geq \mu\|Z^N[t] = z\right) \leq 4\exp(-N \cdot f(\mu - \nu)).$$  \hspace{1cm} (50)

Substituting (50) to (49), we have

$$P_x\left(\|Z^N[t+1] - z[t+1]\| \geq \mu\|Z^N[t] - z[t]\| < \rho\right) \leq 4\exp(-N \cdot f(\mu - \nu)).$$  \hspace{1cm} (51)

Hence from Equation (48) and (51), there exists constants $c_1^{t+1} > 0$ and $c_2^{t+1} > 0$ that do not depend on
Proof: From the belief value evolution (1) we know
\[ b_{0,l}^1 = \frac{r_1 - r_1(p_1 - r_1)l}{1 + r_1 - p_1}, \quad b_{0,l+1}^1 - b_{0,l}^1 = r_1(p_1 - r_1)^l. \]

Therefore
\[ (1 - p_1) + \pi_{0,l}^1 - (l - 1)(\pi_{0,l+1}^1 - \pi_{0,l}^1) \]
\[ = (1 - p_1) + \frac{r_1 - r_1(p_1 - r_1)}{1 + r_1 - p_1} \cdot r_1 - (l - 1)r_1(p_1 - r_1)^l \]
\[ = (1 - p_1) + \frac{r_1 - r_1(p_1 - r_1)}{1 + r_1 - p_1} \cdot r_1 - (l - 1)r_1(p_1 - r_1)^l \]
\[ = (1 - p_1) + r_1 \left[ \frac{1 - (p_1 - r_1)^l}{1 + r_1 - p_1} - (l - 1)(p_1 - r_1)^l \right] \]
\[ = (1 - p_1) + r_1 \left[ \frac{1 + (l - 1)(p_1 - r_1)^{l+1} - l(p_1 - r_1)^l}{1 + r_1 - p_1} \right] \]
\[ = (1 - p_1) + r_1 \left[ \frac{1 + (l - 1)(p_1 - r_1)^{l+1} - l(p_1 - r_1)^l}{1 + r_1 - p_1} \right] \]
\[ = (1 - p_1) + \frac{r_1}{1 + r_1 - p_1} \left[ (l - 1)(p_1 - r_1)^l(p_1 - r_1 - 1) \right. \]
\[ - (p_1 - r_1 - 1)(p_1 - r_1 + \cdots + (p_1 - r_1)^{l-1}) \]
\[ = (1 - p_1) + r_1 \left[ (1 + (p_1 - r_1) + \cdots + (p_1 - r_1)^{l-1}) \right. \]
\[ - (l - 1)(p_1 - r_1)^l \] (53)

Since \((p_1 - r_1)^l \geq (p_1 - r_1)^l\) for \(l = 1, \cdots, j - 1\), therefore from equation (53),
\[ (1 - p_1) + \pi_{0,l}^1 - (l - 1)(\pi_{0,l+1}^1 - \pi_{0,l}^1) \]
\[ \geq (1 - p_1) + r_1 > 0, \]
which proves the lemma.
