Abstract

One of the most unusual complications in cholethiasis is spontaneous cholecystocutaneous fistula, which has only been reported a few times in the literature. We report the case of a 76 year old man who presented with a right hypochondrium subcutaneous abscess, with pain evoked through palpation. No comorbidity in the patient's medical history were noted. Confirmation of cholecystocutaneous fistula was made using the proper diagnostic process, which is computed tomography with contrast media, followed by hepatobiliary MRI. This confirmed the presence of a fistulous pathway between the gallbladder and the skin. The patient underwent cholecystectomy surgery and open laparotomy with en bloc aponeurotic muscle, skin and fistula orifice excision.

Introduction
Spontaneous cholecystocutaneous abscess or fistula is an extremely uncommon complication of gallbladder disease. Less than 100 cases have been described in the literature. The first descriptions of cholecystocutaneous fistula was made by Thelisus in 1670. Later Courvoisier reported 169 cases of biliary fistula in the 19th century. The natural history of the disease has changed from suppurative cholecystitis with spontaneous rupture to operative external drainage of an abscess. Early and effective medical and surgical management of biliary tract disease can prevent this rare condition. Stone obstruction of the biliary tree plays a crucial role in the pathophysiology of the development of this condition; intragallbladder pressure can increase dramatically due to the obstruction of the cystic duct. The unresolved obstruction of the bile outflow compromise gallbladder wall blood circulation, as well as lymphatic drainage, resulting in necrosis of the gallbladder wall with the fistula formation. Once pierced, the gallbladder may drain into the peritoneal cavity, causing peritoneal localized abscess or the abscess can lead into an external fistula due to its adherence to the abdominal wall.

Case report
A 76 year old man was admitted to our University Hospital “Ospedale Vittorio Emenuele” and seen in our surgical department. He presented with a 3 cm tumefaction of the right hypochondrium, surrounded by an erythematous skin area, with small secretion of a yellowing-green material, attributable to a bile leaking (Figure 1). The patient’s medical history was clear from previous medical disease and surgery; he only referred to previous upper right quadrant pain and nonspecific dyspeptic disorder.

An abdominal ultrasound examination revealed the presence of a lesion in the aponeurotic muscle wall, but the possible underlying pathology was unknown. No other signs of pathology were observed. Routine blood work was normal.

Abdominal computed tomography scan with contrast media showed the gallbladder walls had diffuse thickened and blurred edges, and the right and transverse abdominal muscles were almost covered and embedded with minute hypo-dense ailments compatible with relapsing phlogistic processes (Figure 2). Hepatobiliary MRI detected that the gallbladder had anteriorly shifted and adhered to the right abdominal muscles. The side wall showed a break through with consensus purulent collection, which extruded through the thick abdominal wall (Figure 3). Eventually, several different-sized stones were revealed inside the cholecyst. Consequently, a diagnosis of spontaneous cholecystocutaneous fistula was made.

The patient underwent cholecystectomy surgery 10 days after diagnosis, with an open laparotomy with en bloc aponeurotic muscle, skin and fistula orifice excision. In order to have a good abdominal wall reconstruction, a properly shaped Prolene Prosthesis was placed using fibrin glue. The patient received broad-spectrum antibiotics after surgery (Piperacillin/Tazobactam 4.5 g, 3 times a day for 5 days via IV).

Considering the patient’s good general condition and good postoperative course, discharge was on the seventh day post-surgery. Surgical wound re-dressing was made one week after discharge in our facility, where the surgical stitches were removed. Scar appearance was good and without concern. No other dressing was needed and the scar was covered with a bandage. The first follow-up was scheduled 15 days after discharge, second one 60 days from discharge. For both follow-ups, routine blood work and surgical scar checking were performed, the results of which were normal and the scar was healing normally.

A histological examination confirmed the diagnosis of chronic cholecystitis with gallstones and cholecystocutaneous fistula.
Discussion
Thanks to the progress made with medical imaging and surgical techniques, biliary fistula is today a very rare pathology8–11. Fistulas often represent the result of post-surgical12 or post-traumatic15 complications that generally involve the duodenum (77%) and colon (15%)16.

Spontaneous cholecystocutaneous fistula represents a truly exceptional event, as confirmed by the analysis of the literature, which revealed only 28 cases published over the last 10 years (Table 1). This disease mainly affects female subjects over the age of 60. Etiology is generally due to an acute inflammatory process as a consequence of a cholecystitis or chronic gallstones disease17–20, although there are described cases of spontaneous cholecystocutaneous fistula in the absence of gallstones21. Rarely does cholecystocutaneous fistula evolve into a neoplastic process. Instead, fistula can be a sign of gallbladder cancer19,20. According to Sibakoti, polyarteritis nodosa with gallbladder vasculitis and prolonged use of high dose steroids can be considered predisposing factors21. Fistula primum movens is by cystic duct obstruction, which increases the pressure within the gallbladder, with wall distension and impaired vascularization, resulting in the formation of focal necrosis of the wall with perforation evolution and abscess formation to the surrounding area that will rupture in to the continuous structures. In the present case, the abscess drained through the abdominal wall and the fistulous pathway originated from the bottom of the gallbladder. This area is the most distant from the cystic artery and physiologically the least vascularized and therefore more susceptible to ischemia17.

The external fistular orifice is usually on the right upper quadrant, but other locations have been described, including the left hypocondrium, umbilical scar, right lumbar, and right iliac fossa, and rarely the right gluteus and breast region.\(^{1,2,3,29}\)

The diagnostic process always begins with upper abdomen ultrasound and ends with hepatobiliary MRI to visualize the biliary tree. Considering that 11% of cholecystitis MRI confirmed the fistula presence and it was not necessary to execute the ERCP before surgery. Although an intraoperative cholangiogram was performed to check that the bile ducts were clear from gallstones. Cholecystocutaneous fistula has always been treated by two different strategies. The first includes a two-step approach: percutaneous drainage and antibiotic therapy, and subsequently cholecystectomy. The second directly involves laparotomy cholecystectomy execution with en block aponeurotic muscles, as well as skin and fistula orifice excision.

The second strategy is the most commonly used since the two-step approach treatment is reserved for patients with sepsis and poor general condition.\(^{1,2,3,29}\)

In 1998, Kumar described the first case of gynecological fistula treated with laparoscopic technique, proposing to the scientific community the feasibility of this innovative approach.\(^{1,2,9,29}\)

Conclusion

Rarity of this pathology confirms the great quality of progress made by early diagnostic techniques and medical treatment to prevent complication of cholelithiasis. Although cholecystocutaneous spontaneous fistula is not common, it can lead to a serious condition. If not quickly treated, it can rapidly evolve into a generalized septic state with severe impairment prognosis. In our case, the patient was in good health arguably because the fistula was draining the most of the abscess outside the body and not in the peritoneum space. Surgical treatment was, however, essential to restore the physiologic bile flow and adequate broad-spectrum antibiotic prophylaxis lowered the risk of post-operative infections. Although laparoscopic approaches have been described since 1998, this pathology is, in most cases, continuing to be treated with open technique, most likely because it is easier and with fewer risks of post-surgical complications.\(^{1,2,3,29}\)

Referee Report 24 November 2017

doi:10.5256/f1000research.13246.r28008

Giuseppe Navarra
Surgical Oncology Unit, Department of Human Pathology of Adult and Evolutive Age, University Hospital of Messina, Messina, Italy

The article Case Report: Spontaneous cholecystocutaneous fistula, a rare cholethiasis complication covers a subject that nowadays is quite uncommon. It goes through the background of the case’s history, it provides details of diagnostic tests, treatment given and outcomes reached. It could be useful for other practitioners. It can be accepted for indexing with minor English revision.

Is the background of the case’s history and progression described in sufficient detail? Yes

Are enough details provided of any physical examination and diagnostic tests, treatment given and outcomes? Yes

Is sufficient discussion included of the importance of the findings and their relevance to future understanding of disease processes, diagnosis or treatment? Yes

Is the case presented with sufficient detail to be useful for other practitioners? Yes

Competing Interests: No competing interests were disclosed.

I have read this submission. I believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

Referee Report 21 November 2017

Antonino Agrusa
Department of General Surgery, Urgency and Organ Transplantation, University of Palermo, Palermo, Italy
My compliments to the authors for the interesting and rare case report. I approve it for publication in F1000 Research.

Please give more explanation for the 10 days delay between patient admission and operative surgical management. On the basis of rare case report the authors should clarify the operative technique with more details.

Is the background of the case's history and progression described in sufficient detail?
Yes

Are enough details provided of any physical examination and diagnostic tests, treatment given and outcomes?
Yes

Is sufficient discussion included of the importance of the findings and their relevance to future understanding of disease processes, diagnosis or treatment?
Yes

Is the case presented with sufficient detail to be useful for other practitioners?
Partly

Competing Interests: No competing interests were disclosed.

Referee Expertise: General and emergency surgery

I have read this submission. I believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

The authors should clarify the reasons for the 10 days delay in the operative management of their patient.

More insight should be provided on the choice of aggressive operative treatment as compared to a percutaneous drainage. Perhaps the drainage would have been more readily available and also less expensive as compared to elective surgery. Keeping in mind the age of the patient, it might have been a reasonable option proceeding with conservative management and percutaneous drainage trial.

Did the authors investigate the use of somatostatin (provided in the form of Octreotide) in such case? It is currently a first line approach for uncomplicated pancreatic-cutaneous fistulas and might as well work with the Gallbladder considering the physiological functions of the hormone.

All in all the case is interesting and, considering the rarity of the event, it deserves publication.
Is the background of the case's history and progression described in sufficient detail?
Yes

Are enough details provided of any physical examination and diagnostic tests, treatment given and outcomes?
Yes

Is sufficient discussion included of the importance of the findings and their relevance to future understanding of disease processes, diagnosis or treatment?
Yes

Is the case presented with sufficient detail to be useful for other practitioners?
Yes
