(Dated: October 20, 2017)
Abstract

Kinetic equations for quarks and gluons are solved numerically in the relaxation time approximation for the case of one-dimensional boost-invariant geometry. Quarks are massive and described by the Fermi-Dirac statistics, while gluons are massless and obey Bose-Einstein statistics. The conservation laws for the baryon number, energy, and momentum lead to two Landau matching conditions which specify the coupling between the quark and gluon sectors and determine the proper-time dependence of the effective temperature and baryon chemical potential of the system. The numerical results illustrate how a non-equilibrium mixture of quarks and gluons approaches hydrodynamic regime described by the Navier-Stokes equations with appropriate forms of the kinetic coefficients. The shear viscosity of a mixture is the sum of the shear viscosities of quark and gluon components, while the bulk viscosity is given by the formula known for a gas of quarks, however, with the thermodynamic variables characterising the mixture. Thus, we find that massless gluons contribute in a non-trivial way to the bulk viscosity of a mixture, provided quarks are massive. We further observe the hydrodynamization effect which takes place earlier in the shear sector than in the bulk one. The numerical studies of the ratio of the longitudinal and transverse pressures show, to a good approximation, that it depends on the ratio of the relaxation and proper times only. This behaviour is connected with the existence of an attractor solution for conformal systems.

Keywords: relativistic heavy-ion collisions, quark-gluon plasma, relativistic transport theory, Boltzmann equation, relativistic hydrodynamics, shear and bulk viscosities
I. INTRODUCTION

Comparisons between predictions of hydrodynamic models and exact kinetic-theory results have become an important method to verify the validity of hydrodynamic frameworks [1–12] which are now our basic tools to interpret the processes of heavy-ion collisions studied experimentally at RHIC and the LHC [13–17]. Such comparisons allow us also for deeper analyses of mutual relations between effective hydrodynamic models and microscopic, underlying theories [18–21], for a recent review see [22]. In this work we continue earlier studies on this topic and generalise previous results by studying a mixture of massive quarks and massless gluons forming a highly non-equilibrium system. Similarly to earlier works we restrict ourselves to boost-invariant systems [23].

Previous studies of mixtures [24–27] were restricted to the massless case and done mostly in the context of anisotropic hydrodynamics [28, 29]. In this paper we restrict ourselves to the kinetic-theory study, leaving an anisotropic hydrodynamics context for a separate investigation. Nevertheless, we use here the results of the first-order Navier-Stokes hydrodynamics to demonstrate the process of hydrodynamization of the system [30]. We find that the hydrodynamization in the shear sector (equalisation of the longitudinal, $P_L$, and transverse, $P_T$, pressures) takes place earlier than the hydrodynamization in the bulk sector (equalisation of the average and equilibrium pressures).

In order to study the system behavior close to equilibrium we determine the shear and bulk viscosities of a mixture and find that the shear viscosity $\eta$ is simply a sum of the quark and gluon shear viscosities, $\eta = \eta_Q + \eta_G$. On the other hand, the bulk viscosity of a mixture is given by the formula known for a massive quark gas, $\zeta$. Nevertheless, we find that $\zeta$ depends on thermodynamic coefficients characterising the whole mixture rather than quarks alone, which means that massless gluons contribute in a non-trivial way to the bulk viscosity (provided the quarks are massive).

Interestingly, our studies of the time evolution of the ratio of the longitudinal and transverse pressures indicate that, to a very good approximation, it depends on the ratio of the relaxation and proper times only. This behaviour is related to the presence of an attractor which was found and discussed earlier for conformal systems [31–36], and, quite recently, also for non-conformal ones [37].

The paper is organised as follows: In Secs. II and III we introduce the system of kinetic
equations for the quark-gluon mixture and study their momentum moments. This leads to two Landau matching conditions related to the baryon number and energy-momentum conservation. In Sec. IV we discuss an algebraic method useful for dealing with tensors describing our main observables. This method is used in Secs. V, VI, and VII to calculate various thermodynamic variables for systems exhibiting isotropic, anisotropic, and exact distribution functions, respectively. In Sec. VIII, which is central analytic part of this work, we discuss the conservation laws and present two integral equations used to determine the proper-time dependence of the effective temperature and baryon chemical potential. In Sec. IX we present our results describing proper-time dependence of various quantities, hydrodynamization process, and scaling properties of the $P_L/P_T$ ratio. We summarise and conclude in Sec. X. Appendices A, B and C contain: details of the calculations of the generalised thermodynamic functions, discussion of the Navier-Stokes equations, and the explicit calculation of the shear and bulk viscosities for a quark-gluon mixture, respectively.

In this work we use $x^\mu = (t, x, y, z)$ and $p^\mu = (p^0 = E_p, p_x, p_y, p_z = p_L)$ to denote the particle space-time position and four-momentum. The longitudinal ($z$) direction corresponds to the beam axis. The transverse momentum is $p_T = \sqrt{p_x^2 + p_y^2}$ and particles are assumed to be always on the mass shell, $E_p = \sqrt{m^2 + p_T^2 + p_L^2}$. The scalar product of two four-vectors is $a^\mu b_\mu = a^\mu g_{\mu\nu} b^\nu \equiv a \cdot b$ where $g^{\mu\nu} = \text{diag} (1, -1, -1, -1)$ is the metric tensor. For the partial derivative we use the notation $\partial_\mu \equiv \partial / \partial x^\mu$. Throughout the paper we use natural units with $c = k_B = \hbar = 1$.

II. KINETIC EQUATIONS

Our analysis is based on three coupled relativistic Boltzmann transport equations for quark, antiquark, and gluon phase-space distribution functions $f_s(x, p)$ \cite{24–27},

\[ (p \cdot \partial) f_s(x, p) = C[f_s(x, p)], \quad s = Q^+, Q^-, G. \]  

(1)

The collisional kernel $C$ in (1) is treated in the relaxation time approximation (RTA) \cite{38–41}

\[ C[f_s(x, p)] = (p \cdot U) \frac{f_{s,eq}(x, p) - f_s(x, p)}{\tau_{\text{eq}}}, \]  

(2)

where $\tau_{\text{eq}}$ is the relaxation time and the four-vector $U(x)$ describes the hydrodynamic flow. In numerical calculations we assume that $\tau_{\text{eq}}$ is constant, which explicitly breaks conformal
symmetry of the system. The other source of breaking of the conformal symmetry is a finite quark mass. The form of \( U^\mu(x) \) in (1) is defined by choosing the Landau hydrodynamic frame. We note, however, that for one-dimensional boost-invariant systems the structure of \( U^\mu(x) \) follows directly from the symmetry arguments, see Sec. VII A.

In Eq. (2) the functions \( f_{s,eq}(x,p) \) are standard equilibrium distribution functions, which (unless specified otherwise) take the Fermi-Dirac and Bose-Einstein forms for (anti)quarks and gluons, respectively,

\[
\begin{align*}
    f_{Q^\pm,eq}(x,p) &= h_{eq}^+ \left( \frac{p \cdot U \mp \mu}{T} \right), \\
    f_{G,eq}(x,p) &= h_{eq}^- \left( \frac{p \cdot U}{T} \right).
\end{align*}
\]

Here \( T(x) \) is the effective temperature, \( \mu(x) \) is the effective chemical potential of quarks, and

\[
h_{eq}^\pm(a) = \left[ \exp(a) \pm 1 \right]^{-1}.
\]

The same value of \( T(x) \) appearing in Eqs. (3) and (4), as well as the same value of \( \mu(x) \) appearing in the quark and antiquark distributions in Eq. (3) introduces interaction between quarks, antiquarks and gluons – all particles evolve toward the same local equilibrium defined by \( T(x) \) and \( \mu(x) \). Since the baryon number of quarks is 1/3, we can use the relation

\[
\mu = \frac{\mu_B}{3},
\]

with \( \mu_B \) being the baryon chemical potential.

All particles are assumed to be on the mass shell, \( p^2 = p \cdot p = m^2 \), so that the invariant momentum measure is

\[
\int dP(...) \equiv 2 \int d^3p \Theta(p \cdot t) \delta(p^2 - m^2)(...) = \int \frac{d^3p}{E_p}(...),
\]

where \( \Theta \) is the Heaviside step function and \( t^\mu \) is an arbitrary time-like four-vector. Hereafter, the gluons are treated as massless, while quarks have a finite constant mass \( m \).

### III. MOMENTS OF THE KINETIC EQUATIONS

We introduce the \( n \)-th moment operator in the momentum space

\[
\hat{T}^{\mu_1 \cdots \mu_n}(...) \equiv \int dP p^{\mu_1} p^{\mu_2} \cdots p^{\mu_n}(...),
\]

5
with the zeroth moment operator defined as

\[ \hat{I}(\ldots) \equiv \int dP (\ldots). \]  

(9)

Acting with \( \hat{I}^{\mu_1 \cdots \mu_n} \) on the distribution functions \( f_s(x,p) \) and multiplying them by the degeneracy factors \( k_s \), one obtains the \( n \)-th moments of the distribution functions

\[ T_s^{\mu_1 \cdots \mu_n} \equiv k_s \hat{I}^{\mu_1 \cdots \mu_n} f_s(x,p). \]  

(10)

Here \( k_s \equiv g_s/(2\pi)^3 \), with \( g_{Q^{\pm}} = 3 \times 2 \times N_f \) and \( g_G = 8 \times 2 \) being the internal degeneracy factors for (anti)quarks and gluons, respectively. In our calculations we assume that we deal with two (up and down) quark flavors with equal mass, which reflects the SU(2) isospin symmetry.

With the above definitions, the first and second moments of the distribution functions read

\[ N_s^\mu(x) \equiv T_s^\mu = k_s \int dP p^\mu f_s(x,p), \]  

(11)

\[ T_s^{\mu\nu}(x) \equiv T_s^{\mu\nu} = k_s \int dP p^\mu p^\nu f_s(x,p), \]  

(12)

which are identified with the particle number current and the energy-momentum tensor of the species “s”, respectively. In addition, we define the baryon number current

\[ B^\mu(x) \equiv \sum_s q_s N_s^\mu(x) = \frac{k_{Q^\pm}}{3} \int dP p^\mu \left[ f_{Q^+}(x,p) - f_{Q^-}(x,p) \right], \]  

(13)

where \( q_s = \{1/3, -1/3, 0\} \) is the baryon number for quarks, antiquarks, and gluons, respectively. The total particle number current and total energy-momentum tensor read

\[ N^\mu(x) = \sum_s N_s^\mu(x), \]  

(14)

\[ T^{\mu\nu}(x) = \sum_s T_s^{\mu\nu}(x). \]  

(15)

We now consider the \( n \)-th moments of the kinetic equations (1), which are obtained by acting with the operator \( \hat{I}^{\mu_1 \cdots \mu_n} \) given by (8) on their left- and right-hand sides and multiplying them by the degeneracy factors \( k_s \). The zeroth and first moments have the form

\[ k_s \hat{I}^\mu p^\mu \partial_\mu f_s(x,p) = k_s \hat{I}^\mu p^\mu U_\mu \frac{f_{s,eq}(x,p) - f_s(x,p)}{\tau_{eq}}, \]  

(16)

\[ k_s \hat{I}^\nu p^\mu \partial_\mu f_s(x,p) = k_s \hat{I}^\nu p^\mu U_\mu \frac{f_{s,eq}(x,p) - f_s(x,p)}{\tau_{eq}}, \]  

(17)
which, using Eqs. (10)–(12), may be rewritten as

$$\partial_\mu N^\mu_s = U_\mu \frac{N^\mu_{s,eq} - N^\mu_s}{\tau_{eq}},$$  \hspace{1cm} (18)

$$\partial_\mu T^\mu_\nu_s = U_\mu \frac{T^\mu_\nu_{s,eq} - T^\mu_\nu_s}{\tau_{eq}}.$$  \hspace{1cm} (19)

Taking difference between $s = Q^+$ and $s = Q^-$ components of Eqs. (18) we obtain the baryon current evolution equation

$$\partial_\mu B^\mu = U_\mu \frac{B^\mu_{eq} - B^\mu}{\tau_{eq}}.$$  \hspace{1cm} (20)

On the other hand, when taking the sum over “$s$” components of Eqs. (19) one gets the total energy and momentum conservation equation

$$\partial_\mu T^\mu_\nu = U_\mu \frac{T^\mu_\nu_{eq} - T^\mu_\nu}{\tau_{eq}}.$$  \hspace{1cm} (21)

In order to have the baryon number conserved it is required that the left-hand side of Eq. (20) vanishes, $\partial_\mu B^\mu = 0$. The latter implies vanishing of the right-hand side of Eq. (20), which leads to the *Landau matching condition for baryon current*

$$U_\mu B^\mu_{eq} = U_\mu B^\mu.$$  \hspace{1cm} (22)

Analogously, the energy and momentum conservation means that the left-hand side of Eq. (21) vanishes, $\partial_\mu T^\mu_\nu = 0$. This condition results in vanishing of the right-hand side of Eq. (21), which leads to the *Landau matching condition for energy and momentum*

$$U_\mu T^\mu_\nu_{eq} = U_\mu T^\mu_\nu.$$  \hspace{1cm} (23)

IV. TENSOR DECOMPOSITION

It is convenient to introduce the four-vector basis \cite{42, 43}

$$(A_{(0)}, A_{(1)}, A_{(2)}, A_{(3)}) = (U, X, Y, Z),$$  \hspace{1cm} (24)

which in the local rest frame (LRF) reads

$$A^\mu_{(0),LRF} \equiv U^\mu_{LRF} = (1, 0, 0, 0),$$

$$A^\mu_{(1),LRF} \equiv X^\mu_{LRF} = (0, 1, 0, 0),$$

$$A^\mu_{(2),LRF} \equiv Y^\mu_{LRF} = (0, 0, 1, 0),$$

$$A^\mu_{(3),LRF} \equiv Z^\mu_{LRF} = (0, 0, 0, 1).$$  \hspace{1cm} (25)
Using Eqs. (25) one may express the metric tensor as follows [44]
\[ g^{\mu\nu} = U^\mu U^\nu - \sum_{A \neq U} A^\mu A^\nu. \] (26)

The projector on the space orthogonal to the four-velocity, \( \Delta^{\mu\nu} \equiv g^{\mu\nu} - U^\mu U^\nu \), takes the form
\[ \Delta^{\mu\nu} = - \sum_{A \neq U} A^\mu A^\nu, \] (27)
and satisfies the conditions \( U_\mu \Delta^{\mu\nu} = 0 \), \( \Delta^{\mu}_{\alpha} \Delta^{\alpha\nu} = \Delta^{\mu\nu} \) and \( \Delta^{\mu}_{\mu} = 3 \). The basis (25) is a unit one in the sense that
\[ A \cdot B = \begin{cases} 0 & \text{for } A \neq B, \\ 1 & \text{for } A = B = U, \\ -1 & \text{for } A = B \neq U, \end{cases} \] (28)
and complete so that any four-vector may be decomposed in the basis \( A^{(\alpha)} \). In particular, one may express the particle number flux as follows
\[ N^\mu_s(x) = \sum_A n^s_A A^\mu, \] (29)
where the coefficients \( n^s_A \), due to Eqs. (28), are given by the projections
\[ n^s_A = A_\mu N^\mu_s(x) A^2, \] (30)
with \( A^2 = A \cdot A \) (note that \( A^2 = -1 \) for space-like four-vectors of the basis (25)). The tensorial basis for the rank-two tensors is constructed using tensor products of the basis four-vectors \( A^{(\mu)} \). Thus the decomposition of the energy-momentum tensor takes the form
\[ T^{\mu\nu}_s(x) = \sum_{A,B} t^s_{AB} A^\mu B^\nu, \] (31)
with the components of \( T^{\mu\nu}_s(x) \) defined in the following way
\[ t^s_{AB} = A_\mu B_\nu T^{\mu\nu}_s(x) A^2 B^2. \] (32)

Using Eqs. (11) and (12) in Eqs. (30) and (32) in one gets
\[ n^s_A = k_s \int dP \ (p \cdot A) A^2 f_s(x,p), \] (33)
\[ t^s_{AB} = k_s \int dP \ (p \cdot A) (p \cdot B) A^2 B^2 f_s(x,p). \] (34)
V. ISOTROPIC DISTRIBUTIONS

In the case of momentum-isotropic distribution functions (in particular, in the case of equilibrium distribution functions \( f_{s,eq}(x,p) = f_{s,eq}(p\cdot U(x)) \), as defined by Eqs. (3) and (4)), which are invariant with respect to \( SO(3) \) rotations in the three-momentum space, by the symmetry of the integrands in Eqs. (33) and (34) one has

\[
\begin{align*}
n_{s,eq}^A &= k_s \int dP (p \cdot A) A^2 f_{s,eq} = 0 \quad \text{if} \ A \neq U, \\
t_{s,eq}^{AB} &= k_s \int dP (p \cdot A) (p \cdot B) A^2 B^2 f_{s,eq} = 0 \quad \text{if} \ A \neq B,
\end{align*}
\]

so that for the momentum-isotropic state Eqs. (29) and (31) have the following structure

\[
\begin{align*}
N_{s,eq}^\mu(x) &= N_{s,eq} U_\mu, \\
T_{s,eq}^{\mu\nu}(x) &= \mathcal{E}_{s,eq}^{\mu} U_\nu - \mathcal{P}_{s,eq}^{\mu} \Delta^{\mu\nu},
\end{align*}
\]

with

\[
\begin{align*}
N_{s,eq} &= n_{s,eq}, \\
\mathcal{E}_{s,eq} &= t_{s,eq}^{UU}, \\
\mathcal{P}_{s,eq} &= t_{s,eq}^{XX} = t_{s,eq}^{YY} = t_{s,eq}^{ZZ},
\end{align*}
\]

being the particle density, energy density, and pressure in equilibrium. Explicit forms of these expressions are given in App. A 2.

VI. ANISOTROPIC ROMATSCHKE-STRICKLAND DISTRIBUTIONS

It is also useful to consider anisotropic phase-space distributions introduced by Romatschke and Strickland in [45]. In the covariant form they read [24]

\[
\begin{align*}
f_{Q^\pm,a}(x,p) &= h_{eq}^+ \left( \frac{\sqrt{(p \cdot U)^2 + \xi_Q (p \cdot Z)^2} \mp \lambda}{\Lambda_Q} \right), \\
f_{G,a}(x,p) &= h_{eq}^- \left( \frac{\sqrt{(p \cdot U)^2 + \xi_G (p \cdot Z)^2}}{\Lambda_G} \right),
\end{align*}
\]

where \( \xi_Q(x) = \xi_Q^+(x) = \xi_Q^-(x) \) is the quark anisotropy parameter, \( \Lambda_Q(x) = \Lambda_Q^+(x) = \Lambda_Q^-(x) \) is the quark transverse-momentum scale, and \( \lambda(x) \) is the non-equilibrium baryon chemical potential of quarks. Similarly, \( \xi_G(x) \) is the gluon anisotropy parameter and \( \Lambda_G(x) \) is the gluon transverse-momentum scale. The anisotropy parameters \( \xi_s \) vary in the range
\(-1 < \xi_s < \infty\), with the cases \(-1 < \xi_s < 0\), \(0 < \xi_s < \infty\) and \(\xi_s = 0\) corresponding to the prolate, oblate and isotropic momentum distribution, respectively.

The distributions defined by Eqs. (40) and (41) are invariant only with respect to \(SO(2)\) rotations around the \(z\) direction in the three-momentum space. In this case one still has

\[
n^s_{A} = 0 \quad \text{if} \ A \neq U, \quad (42)
\]
\[
t^s_{AB} = 0 \quad \text{if} \ A \neq B, \quad (43)
\]

and Eqs. (11) and (12) have the following structure [46]

\[
\mathcal{N}^{\mu s}_{a}(x) = \mathcal{N}^{s, a} U^{\mu}, \quad (44)
\]
\[
T^{\mu \nu}_{s, a}(x) = \mathcal{E}^{s, a} U^{\mu} U^{\nu} - \mathcal{P}^{s, a} \Delta_{T}^{\mu \nu} + \mathcal{P}^{s, a} Z^{\mu} Z^{\nu}, \quad (45)
\]

with

\[
\mathcal{N}^{s, a} = n^{s, a}_U, \quad \mathcal{E}^{s, a} = t^{s, a}_{UU}, \quad \mathcal{P}^{s, a} = t^{s, a}_{XX} = t^{s, a}_{YY}, \quad \mathcal{P}^{s, a}_L = t^{s, a}_{ZZ}. \quad (46)
\]

Here \(\Delta_{T}^{\mu \nu} = - (X^{\mu} X^{\nu} + Y^{\mu} Y^{\nu})\) is the projection operator orthogonal to \(U\) and \(Z\). Explicit forms of Eqs. (46) are given in App. A 1.

\section*{VII. EXACT SOLUTIONS OF THE KINETIC EQUATIONS}

In order to solve Eqs. (22) and (23) we need to know the form of the distribution functions \(f_s(x,p)\) being solutions of the kinetic equations (1). In general, such solutions are difficult to find and Eqs. (1) may be at best solved numerically. However, it is possible to find \textit{formal} analytic solutions of Eqs. (1) in the case where the system is boost invariant and transversally homogeneous. Below, we discuss this case in more detail.

\subsection*{A. Boost-invariance and transversal homogeneity}

Hereafter, we assume that the considered system is boost-invariant in the longitudinal (beam) direction and homogeneous in the transverse direction. In such a case we may
choose \[42\]

\[U^\mu = (t/\tau, 0, 0, z/\tau), \quad (47)\]

\[X^\mu = (0, 1, 0, 0), \quad (48)\]

\[Y^\mu = (0, 0, 1, 0), \quad (49)\]

\[Z^\mu = (z/\tau, 0, 0, t/\tau), \quad (50)\]

where \(\tau\) is the (longitudinal) proper time

\[\tau = \sqrt{t^2 - z^2}. \quad (51)\]

As a result the system becomes effectively one-dimensional. Since its evolution is governed completely by the proper time that mixes \(t\) and \(z\), one usually refers to such a system as (0+1)-dimensional.

**B. Boost-invariant Bialas-Czyz variables**

In the case of (0+1)-dimensional system exhibiting symmetries discussed in the previous section it is convenient to use the variables \(w\) and \(v\) which are defined as follows \[47, 48\]

\[w = t p_L - z E_p = -\tau p \cdot Z, \quad (52)\]

\[v = t E_p - z p_L = \tau p \cdot U. \quad (53)\]

Due to the fact that particles are on the mass shell \(w\) and \(v\) are related by the formula

\[v(\tau, w, p_T) = \sqrt{w^2 + (m^2 + p_T^2) \tau^2}. \quad (54)\]

Equations (52) and (53) can be inverted to express the energy and longitudinal momentum of a particle in terms of \(w\) and \(v\), namely

\[E_p = \frac{vt + wz}{\tau^2}, \quad p_L = \frac{wt + vz}{\tau^2}. \quad (55)\]

The Lorentz invariant momentum-integration measure can be written now as

\[dP = \frac{d^3p}{E_p} = \frac{dw \, d^2p_T}{v}. \quad (56)\]

For boost-invariant systems, all scalar functions of space and time, such as the effective temperature \(T\) and quark chemical potential \(\mu\), may depend only on \(\tau\). In addition, one can check that the phase-space distribution functions (which are Lorentz scalars) may depend only on the variables \(w\), \(\tau\) and \(p_T\). We use these properties in the next section.
C. Formal solutions of the kinetic equations

With the help of the variables $w$, $v$ and $p_T$ we can rewrite (1) in a simple form [1, 2, 49, 50]

$$\frac{\partial f_s(\tau, w, p_T)}{\partial \tau} = f_{s, eq}(\tau, w, p_T) - f_s(\tau, w, p_T),$$

(57)

where the boost-invariant versions of the equilibrium distribution functions are straightforward to find using (52) and (53)

$$f_{Q, eq}(\tau, w, p_T) = h_{eq}^+ \left( \frac{\sqrt{\left(\frac{w}{\tau}\right)^2 + p_T^2 + m^2 - \mu}}{T} \right),$$

(58)

$$f_{G, eq}(\tau, w, p_T) = h_{eq}^- \left( \frac{\sqrt{\left(\frac{w}{\tau}\right)^2 + p_T^2}}{T} \right).$$

(59)

Below we assume that distribution functions $f_s(\tau, w, p_T)$ are even functions of $w$, and depend only on the magnitude of $p_T$ \(^1\),

$$f_s(\tau, w, p_T) = f_s(\tau, -w, p_T).$$

(60)

The formal solutions of Eqs. (57) have the form [1, 2, 49, 50]

$$f_s(\tau, w, p_T) = D(\tau, \tau_0) f_s^0(w, p_T) + \int_{\tau_0}^{\tau} d\tau' D(\tau, \tau') f_{s, eq}(\tau', w, p_T).$$

(61)

where $f_s^0(w, p_T) \equiv f_s(\tau_0, w, p_T)$ is the initial distribution function (we have introduced here the notation $\tau_{eq}' = \tau_{eq}(\tau')$ for the general case where the equilibration time may depend on the proper time).

D. Damping function

In Eq. (61) we have introduced the damping function

$$D(\tau_2, \tau_1) = \exp \left[ -\int_{\tau_1}^{\tau_2} \frac{d\tau''}{\tau_{eq}(\tau'')} \right].$$

(62)

\(^1\) In our analysis we restrict ourselves to the initial distributions in the RS form, which are SO(2) invariant in transverse momentum space and thus depend only on the magnitude of $p_T$. 

12
The function $D(\tau_2, \tau_1)$ satisfies the two differential relations
\[
\frac{\partial D(\tau_2, \tau_1)}{\partial \tau_2} = -\frac{D(\tau_2, \tau_1)}{\tau_{eq}(\tau_2)}, \quad \frac{\partial D(\tau_2, \tau_1)}{\partial \tau_1} = \frac{D(\tau_2, \tau_1)}{\tau_{eq}(\tau_1)} \tag{63}
\]
and converges to unity if the two arguments are the same, $D(\tau, \tau) = 1$. These properties imply the identity [26]
\[
1 = D(\tau, \tau_0) + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}(\tau')} D(\tau, \tau'). \tag{64}
\]
For a constant relaxation time used in this work Eq. (62) reduces to
\[
D(\tau_2, \tau_1) = \exp \left[ -\frac{\tau_2 - \tau_1}{\tau_{eq}} \right]. \tag{65}
\]

E. Initial distributions

In what follows we assume that the initial distributions $f_s^0(w, p_T)$ are given by the anisotropic Romatschke-Strickland (RS) forms $f_{s,a}^0(w, p_T)$ which follow from Eqs. (40) and (41),
\[
f_{Q,\pm,a}(\tau_0, w, p_T) = h_{\pm eq}^+ \left( \sqrt{(1 + \xi_Q^0) \left( \frac{w}{\tau_0} \right)^2 + m^2 + p_T^2 + \lambda^0} \right), \tag{66}
\]
\[
f_{G,a}(\tau_0, w, p_T) = h_{eq}^- \left( \sqrt{(1 + \xi_G^0) \left( \frac{w}{\tau_0} \right)^2 + p_T^2} \right). \tag{67}
\]
Here $\xi_s^0 \equiv \xi_s(\tau_0)$, $\Lambda_s^0 \equiv \Lambda_s(\tau_0)$, and $\lambda^0 \equiv \lambda(\tau_0)$ are initial parameters.

In view of the form (61), the use of Eqs. (40) and (41) implies that the decomposition of the particle current and the energy-momentum tensor for (61) has the form of Eqs. (44) and (45), namely
\[
N^\mu_s(x) = N^s U^\mu, \tag{67}
\]
\[
T_s^{\mu\nu}(x) = E^s U^\mu U^\nu - \mathcal{P}_T^s \Delta_T^{\mu\nu} + \mathcal{P}_L^s Z^\mu Z^\nu, \tag{68}
\]
with
\[
N^s = n_U^s, \quad E^s = t_{UU}^s, \quad \mathcal{P}_T^s = t_{XX}^s = t_{YY}^s, \quad \mathcal{P}_L^s = t_{ZZ}^s. \tag{69}
\]
Hereafter, we refer to results obtained with the solution (61) as the kinetic or exact ones.
A. Baryon number conservation

Using the expression for the baryon number current (13) and the decompositions (37) and (67) one may rewrite Eq. (22) as

\[ B^\text{eq} = B, \]  

(70)

where we define the equilibrium and exact baryon number densities as

\[ B^\text{eq} = \frac{1}{3} \left( N_{Q^+} - N_{Q^-} \right), \quad B = \frac{1}{3} \left( N_{Q^+}^\text{eq} - N_{Q^-}^\text{eq} \right). \]  

(71)

The explicit formula for \( B^\text{eq}(\tau) \) is derived in App. A 2, see Eq. (A33),

\[ B^\text{eq}(\tau) = \frac{16\pi k_Q T^3}{3} \sinh \left( \frac{\mu}{T} \right) H_B \left( \frac{m}{T}, \frac{\mu}{T} \right), \]  

(72)

where the function \( H_B \) is defined by Eq. (A21). The formula for \( B(\tau) \) is more complicated and is given in App. A 3, see Eq. (A43). It contains an integral over the time history of the functions \( T' \equiv T(\tau') \) and \( \mu' \equiv \mu(\tau') \) in the range \( \tau_0 \leq \tau' \leq \tau \). Consequently, Eq. (70) becomes an integral equation

\[ T^3 \sinh \left( \frac{\mu}{T} \right) H_B \left( \frac{m}{T}, \frac{\mu}{T} \right) = \frac{\tau_0}{\tau} \left( \frac{\Lambda_0^2}{\Lambda_Q^2} \right)^3 \sinh \left( \frac{\lambda^0}{\Lambda_Q^0} \right) H_B \left( \frac{m}{\Lambda_Q^0}, \frac{\lambda^0}{\Lambda_Q^0} \right) D(\tau, \tau_0) \]

\[ + \int_{\tau_0}^\tau \frac{d\tau'}{\tau_{\text{eq}}} D(\tau, \tau') \frac{\tau'}{\tau} \left( \frac{T'}{T} \right)^3 \sinh \left( \frac{\mu'}{T'} \right) H_B \left( \frac{m}{T'}, \frac{\mu'}{T'} \right). \]  

(73)

Equation (73) is a single equation for two functions, \( T(\tau) \) and \( \mu(\tau) \). The second necessary equation required for their determination is obtained from the Landau matching condition for the energy, which we discuss in the next section.

Meanwhile, it is interesting to notice that Eq. (73) can be rewritten as an integral equation for the function \( B(\tau) \), namely

\[ B(\tau) = \frac{\tau_0}{\tau} B(\tau_0) D(\tau, \tau_0) + \int_{\tau_0}^\tau \frac{d\tau'}{\tau_{\text{eq}}} \frac{\tau'}{\tau} B(\tau') D(\tau, \tau'). \]  

(74)
By differentiating (74) with respect to \( \tau \) we get
\[
\frac{dB(\tau)}{d\tau} + \frac{B(\tau)}{\tau} = 0, \tag{75}
\]
which is nothing else but the form of baryon number conservation law valid for the Bjorken geometry (in the original Bjorken paper [23] the same equation was obtained for the conserved entropy current). Equation (75) has scaling solution
\[
B(\tau) = \frac{\tau_0}{\tau} B(\tau_0). \tag{76}
\]
Combining (70) and (72) with (76) we find the equation
\[
\sinh \left( \frac{\mu}{T} \right) \mathcal{H}_B \left( \frac{m}{T}, \frac{\mu}{T} \right) = \frac{3\tau_0 B(\tau_0)}{16\pi k_Q T^3}, \tag{77}
\]
which allows to determine \( \mu \) in terms of \( T \) and \( \tau \) for a given initial baryon number density. Unfortunately, in the general case we study (Fermi-Dirac statistics for quarks) Eq. (77) is an implicit equation for \( \mu \). The situation simplifies in the case of classical statistics, where the function \( \mathcal{H}_B \) becomes independent of \( \mu \).

**B. Four-momentum conservation**

Using the expression for the energy-momentum tensor (15) and the decompositions (38) and (68) one may rewrite Eq. (23) as
\[
E^{eq} = E, \tag{78}
\]
where \( E^{eq} \) and \( E \) contain contributions from quarks, antiquarks, and gluons
\[
E^{eq} = E^{Q^+,eq} + E^{Q^-,eq} + E^{G,eq}, \tag{79}
\]
\[
E = E^{Q^+} + E^{Q^-} + E^G. \tag{80}
\]
Using Eqs. (A26), (A30), (A36), and (A40) we obtain
\[ T^4 \left[ \bar{\mathcal{H}}^+ \left( \frac{1}{\bar{T}}, \frac{m}{\bar{T}}, -\frac{\mu}{\bar{T}} \right) + \bar{\mathcal{H}}^+ \left( \frac{1}{\bar{T}}, \frac{m}{\bar{T}}, \frac{\mu}{\bar{T}} \right) + r \bar{\mathcal{H}}^- \left( 1, 0, 0 \right) \right] = \left( \Lambda_0^Q \right)^4 \left[ \bar{\mathcal{H}}^+ \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_0^Q}}, \frac{m}{\Lambda_0^Q}, -\frac{\lambda_0^Q}{\Lambda_0^Q} \right) + \bar{\mathcal{H}}^+ \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_0^Q}}, \frac{m}{\Lambda_0^Q}, \frac{\lambda_0^Q}{\Lambda_0^Q} \right) \right] D(\tau, \tau_0) \]

\[ + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}} D(\tau, \tau') (T')^4 \left[ \bar{\mathcal{H}}^+ \left( \frac{\tau'}{\tau', \frac{m}{\tau'}, -\frac{\mu'}{\tau'}} \right) + \bar{\mathcal{H}}^+ \left( \frac{\tau'}{\tau', \frac{m}{\tau'}, \frac{\mu'}{\tau'}} \right) \right] \]

\[ + r \left[ \left( \Lambda_0^G \right)^4 \bar{\mathcal{H}}^- \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_0^Q}}, 0, 0 \right) D(\tau, \tau_0) + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} D(\tau, \tau') (T')^4 \bar{\mathcal{H}}^- \left( \frac{\tau'}{\tau}, 0, 0 \right) \right] , \tag{81} \]

where the functions \( \bar{\mathcal{H}}^\pm \) are defined by Eqs. (A9) and \( r \) is the ratio of the degeneracy factors

\[ r = \frac{k_G}{k_Q} = \frac{g_G}{g_Q} = \frac{4}{3}. \tag{82} \]

Equations (73) and (81) are two integral equations that are sufficient to determine the proper-time dependence of the functions \( T(\tau) \) and \( \mu(\tau) \). This is done usually by the iterative method [51]. The two initial, to large extent arbitrary, input functions \( T_{in}(\tau) \) and \( \mu_{in}(\tau) \) are used on the right-hand sides of (73) and (81) and the new values \( T_{out}(\tau) \) and \( \mu_{out}(\tau) \) are calculated from the left-hand sides. They are next used as \( T_{in}(\tau) \) and \( \mu_{in}(\tau) \) on the right-hand sides to get updated values of \( T_{out}(\tau) \) and \( \mu_{out}(\tau) \). Such procedure is repeated until the updated values agree well with the initial values. We have found that the stable results are obtained with about 50 iterations if the final proper time is 5.0 fm. The time of the calculations grows quadratically with the final proper time.

Our use of the two coupled integral equations is similar to the case studied previously in [52]. We find that it is more straightforward than using (81) together with (77). However, the situation is different in the case of classical statistics, where (77) can be used to determine analytically \( \mu/T \). In this case, the expression for \( \mu/T \) obtained from (77) may be substituted into (81) and we are left with a single integral equation for the function \( T(\tau) \).

One may check, using (A18) and (A19), that Eq. (81) is consistent with the formula

\[ \frac{dE}{d\tau} = -\frac{E + \mathcal{P}_L}{\tau}, \tag{83} \]

where \( \mathcal{P}_L = \mathcal{P}_L^{Q^+} + \mathcal{P}_L^{Q^-} + \mathcal{P}_L^G \) is the total longitudinal momentum of the system. Equation (83) holds in general for the Bjorken expansion. It follows directly from the conservation law in the form \( \partial_\mu T^{\mu \nu} = 0. \)
FIG. 1: (Color online) Effective temperature $T$ (upper panels) and $\mu/T$ ratio (lower panels), shown as functions of the proper time $\tau$ and normalized to unity at the initial proper time $\tau = \tau_0$. Results correspond to the initial oblate-oblate configuration with the anisotropy parameters given in the figure. Three different types of lines correspond to three different choices of the statistics and the quark mass (the label “cs” denotes classical statistics used for both quarks and gluons, while the label “qs” denotes the use of Fermi-Dirac and Bose-Einstein statistics for quarks and gluons, respectively). Other parameters of the calculations are shown in the figure and discussed in the text.

IX. RESULTS

In this section we present the results of our numerical calculations. In all studied cases we use a constant equilibration time $\tau_{eq} = 0.25 \text{ fm}$, which is the same for quark and gluon components.\footnote{Here the main motivation comes from saving the computational time. A popular case used in conformal theories, where $\tau_{eq}$ is inversly proportional to the effective temperature $T$, leads to much longer calculations} The starting proper time is $\tau_0 = 0.1 \text{ fm}$ and the evolution continues till
\[ T_0(x_Q) = -0.5 \]
\[ x_G = 10 \]
\[ B_0 = 0.001 \text{ fm}^{-3} \]

\[ B_0 = 1 \text{ fm}^{-3} \]

\[ \mu_T(0)/\mu_T \]

\[ m = 300 \text{ MeV}, \text{qs} \]
\[ m = 300 \text{ MeV}, \text{cs} \]
\[ m = 1 \text{ MeV}, \text{cs} \]

**FIG. 2**: (Color online) Same as Fig. 1 but for the initial prolate-oblate configuration with the parameters given in the figure.

\[ \tau_f = 5.0 \text{ fm} (\text{or } \tau_f = 10 \text{ fm in several cases}). \] The initial transverse momentum scales of quarks and gluons are taken identical and always fixed to \( \Lambda_Q^0 = \Lambda_G^0 = 1 \text{ GeV}. \) The initial non-equilibrium chemical potential \( \lambda_0 \) is chosen in such a way that the initial baryon number density is either \( B_0 = 0.001 \text{ fm}^{-3} \) or \( B_0 = 1 \text{ fm}^{-3} \), see Eq. (A43).

Other initial conditions correspond to different values of the anisotropy parameters. We use three sets of the values for \( \xi_Q^0 \) and \( \xi_G^0 \): i) \( \xi_Q^0 = 1 \) and \( \xi_G^0 = 10 \), ii) \( \xi_Q^0 = -0.5 \) and \( \xi_G^0 = 10 \), and iii) \( \xi_Q^0 = -0.5 \) and \( \xi_G^0 = -0.25 \). They correspond to oblate-oblate, prolate-oblate, and prolate-prolate initial momentum distributions of quarks and gluons, respectively. Such initial values for \( \xi_Q^0 \) and \( \xi_G^0 \) were used previously in Ref. [27]. We note that different values of \( \xi_Q^0 \), \( \xi_G^0 \), and \( \lambda_0 \) imply different initial energy and baryon number densities, hence, due to matching conditions, also different initial values of \( T_0 \) and \( \mu_0 \). We also note that the oblate-
FIG. 3: (Color online) Same as Figs. 1 and 2 but for the initial prolate-prolate configuration with the parameters given in the figure.

oblate initial configuration is supported by the microscopic calculations which suggest that the initial transverse pressure is much higher than the longitudinal one [30, 53].

We perform our calculations for three different choices of the particle statistics and the quark mass: in the first case both quarks and gluons are described by the classical, Boltzmann statistics and the quark mass is equal to 1 MeV, in the second case we use again the classical statistics but the quark mass is 300 MeV, finally, in the third case the quarks are described by the Fermi-Dirac statistics and have the mass of 300 MeV, while the gluons are described by the Bose-Einstein statistics. The gluon mass is always set equal to zero. The case with classical statistics, $B_0 = 0.001 \text{ fm}^{-3}$, and negligibly small quark mass of 1 MeV agrees well with the exact massless case studied in Ref. [27]. This agreement is used as one

---

3 In this case the ± sign in (5) is neglected and $h_{\pm}^{eq}(a) = \exp(-a)$.

4 Since this value of mass is much smaller than the considered temperature values, we refer sometimes to this case as to the “massless” one.
FIG. 4: (Color online) Proper-time dependence of the ratios $T/T_0$ (a) and $\mu T_0/\mu_0 T$ (b) obtained in the range $\tau_0 < \tau < 10$ fm from: kinetic theory (red solid lines), perfect-fluid hydrodynamics (green dot-dashed lines), and Navier-Stokes hydrodynamics (navy blue dashed lines). All results are normalized to the initial values $T_0$ and $\mu_0$ used in the kinetic theory. The initial values of temperature and chemical potential in the hydrodynamic calculations are chosen in such a way that the final values of $T$ and $\mu$ agree with the values found in the kinetic-theory calculation. The calculations are done for the oblate-oblate initial conditions with a finite quark mass of 300 MeV, quantum statistics, and $B_0 = 1$ fm$^{-3}$.

We note that the values of the initial conditions used in this work are to large extent arbitrary, as we want to analyse here only general features of the solutions of Eqs. (1). With more specific systems in mind, one can choose other values of the initial parameters.
FIG. 5: (Color online) Effective shear viscosity $\eta_{\text{eff}}$ defined by Eq. (84) (red solid line) and the shear viscosity coefficients $\eta$ calculated using Eq. (85) for the two $T(\tau)$ and $\mu(\tau)$ profiles, found from the perfect-fluid hydrodynamics (green dot-dashed line) and from the Navier-Stokes equations (navy blue dashed line). The effective shear viscosity agrees well with the standard definition of $\eta$ for $\tau > 0.5$ fm. The initial conditions are the same as in Fig. 4.

FIG. 6: (Color online) Panel (a): Proper-time dependence of the shear viscosity of the mixture (red solid line), of the quark component (navy blue dashed line), and of the gluon component (green dot-dashed line), see Eqs. (85), (86) and (87). The initial conditions are the same as in Fig. 4. Panel (b): The ratio $\eta_Q/\eta_G$ as a function of $m/T$ and $\mu/T$. The colored line represents the system evolution trajectory with the parameters corresponding to the panel (a).
A. Proper-time dependence of $T$ and $\mu/T$

Figures 1, 2 and 3 show the proper-time dependence of the effective temperature $T$ and $\mu/T$ ratio, which are normalised to unity at the initial time $\tau = \tau_0$. The two upper panels, (a) and (b), show temperature profiles, while the two lower panels, (c) and (d), show $\mu/T$. The two left panels, (a) and (c), correspond to the case $B_0 = 0.001$ fm$^{-3}$, and the two right panels, (b) and (d), describe the case $B_0 = 1$ fm$^{-3}$. The three figures correspond to three different initial conditions specified by the initial anisotropy parameters. Figures 1, 2, and 3 illustrate the effects of the finite mass and quantum statistics on the time evolution of $T$ and $\mu/T$. We observe that the inclusion of the finite mass (for either classical or quantum statistics) has an important effect on the $\mu/T$ ratio. For $m = 300$ MeV it asymptotically increases with time, while in the $m = 1$ MeV case it approaches a constant, which is expected for the massless system in the Bjorken model assuming local equilibrium. The finite mass has a small effect on the time dependence of the effective temperature. The latter decreases more slowly in the massive cases (especially in the $B_0 = 0.001$ fm$^{-3}$ case). The effects of quantum statistics are most visible in the $\mu/T$ proper-time dependence.

To analyze the proper-time dependence of $T$ and $\mu/T$ in more detail, in Fig. 4 we compare the kinetic-theory (KT) results for the quantum, massive, and oblate-oblate case with hydrodynamic calculations. The latter are performed for the Bjorken perfect-fluid (BJ) and Navier-Stokes (NS) versions, see Appendix B for definitions of these frameworks. The initial values of temperature and chemical potential in the hydrodynamic calculations are chosen in such a way that the final values of $T$ and $\mu$ agree with the values found in the kinetic-theory calculation. Although such matching is required only for the last moment of the time evolution, we see that the hydrodynamic calculations approximate very well the kinetic-theory results within a few last fermis of the time evolution. As expected, we see that the Navier-Stokes approach reproduces better the exact kinetic-theory result, compared to the perfect-fluid calculation, as it accounts for the dissipative effects in the system.
FIG. 7: (Color online) Effective bulk viscosity \( \zeta_{\text{eff}} \) defined by Eq. (88) (red line) and the bulk viscosity coefficient \( \zeta \) calculated with the help of Eq. (90) for the two \( T(\tau) \) and \( \mu(\tau) \) profiles, found from the perfect-fluid hydrodynamics (green dot-dashed line) and from the Navier-Stokes equations (blue dashed line). We find that the effective bulk viscosity agrees with the standard definition of \( \zeta \) for \( \tau > 2 \text{ fm} \). The initial conditions are the same as in Fig. 4.

FIG. 8: (Color online) Bulk viscosity coefficient \( \zeta \) calculated with the help of Eq. (90) with the thermodynamic coefficients \( \kappa_1 \) and \( \kappa_2 \) determined for the whole quark-gluon system (red solid line) and the coefficient \( \zeta_0 \) obtained from Eq. (90) with \( \kappa_1 \) and \( \kappa_2 \) determined only for the quark component (blue dashed line). The initial conditions are the same as in Fig. 4.
B. Hydrodynamization

1. Shear sector

The results shown in Fig. 4 suggest that the non-equilibrium dynamics of the system enters rather fast the hydrodynamic regime described by the NS equations (at the stage where deviations from local equilibrium are still substantial). Such a phenomenon was identified first in the context of AdS/CFT calculations [30] and is known now as the hydrodynamization process. To illustrate this behaviour in our case, we show in Fig. 5 the proper-time dependence of the effective shear viscosity coefficient \( \eta_{\text{eff}} \) defined by the expression [2] \(^5\)

\[
\eta_{\text{eff}} = \frac{T}{2} (P_T - P_L),
\]

see Eqs. B3. The effective shear viscosity (solid red line in Fig. 5) is compared with the standard shear viscosity coefficient, \( \eta \), valid for the system close to equilibrium. For the quark-gluon mixture the latter is defined as the sum of the quark and gluon coefficients, \(^6\)

\[
\eta = \eta_Q + \eta_G,
\]

where following [55], see also [56–58], we use

\[
\eta_Q = \frac{g_Q \tau_{\text{eq}}}{15T} \int_0^\infty \frac{dp}{2\pi^2} \frac{p^6}{m^2 + p^2} [f_{Q+,\text{eq}} (1 - f_{Q+,\text{eq}}) + f_{Q-,\text{eq}} (1 - f_{Q-,\text{eq}})],
\]

\[
\eta_G = \frac{g_G \tau_{\text{eq}}}{15T} \int_0^\infty \frac{dp}{2\pi^2} f_{G,\text{eq}} (1 + f_{G,\text{eq}}).
\]

The coefficient \( \eta \) is calculated as a function of \( T \) and \( \mu \) obtained either from the perfect-fluid (green dot-dashed line in Fig. 5) or NS hydrodynamic calculation (navy blue dashed line)

---

\(^5\) We use the notation where calligraphic symbols such as \( E \), \( P_T \) or \( P_L \) refer to exact values obtained from the kinetic theory. In the situations where the system is close to equilibrium and described by the Navier-Stokes hydrodynamics we add the subscript \( NS \). The standard kinetic coefficients describe the systems close to equilibrium, hence, the shear viscosity is defined by the formula \( \eta = \frac{T}{2} (P_T - P_L)_{\text{NS}} \) and the bulk viscosity by \( \zeta = -\tau \Pi_{\text{NS}} \), see App. B. If we use the exact kinetic-theory values on the right-hand sides of these definitions we deal with effective values, which should agree with the standard definitions for systems being close to local equilibrium.

\(^6\) For general collision kernels, the total shear viscosity (although written formally as a sum of the individual contributions) may not be a simple sum of independent terms, for example, see [54].
In Fig. 5. In the two cases we find that $\eta_{\text{eff}}$ agrees very well with $\eta$ for $\tau > 0.5$ fm which is about two times the relaxation time. Thus, in the shear sector we observe a very fast approach to the hydrodynamic NS regime. It is important to notice that the agreement with the NS description is reached when $\eta$ is significantly different from zero, which supports the idea that the hydrodynamic description becomes appropriate before the system thermalises, i.e., before the state of local thermal equilibrium with $P_T \approx P_L$ is reached.

In panel (a) in Fig. 6 we show the proper-time dependence of the shear viscosity of the mixture (red solid line) and compare it with the shear viscosity of the quark component (navy blue dashed line) and the gluon component (green dot-dashed line), see Eqs. (85), (86) and (87). The initial conditions are the same as in Fig. 4. The results shown in Fig. 6 show that the shear viscosity of the mixture is dominated by the shear viscosity of quarks throughout the system evolution. The information complementary to panel (a) is provided in the panel (b) in Fig. 6 where we present the ratio $\eta_Q/\eta_G$ as a function of $m/T$ and $\mu/T$ (contour lines) together with the system trajectory (colored line).

2. Bulk sector

Similarly to the shear-viscosity effects we can analyse the bulk sector, where we define the effective bulk viscosity by the expression

$$\zeta_{\text{eff}} = -\tau \Pi,$$

where $\Pi$ is the exact bulk pressure

$$\Pi = \frac{1}{3} (P_L + 2P_T - 3P_{eq}).$$

The time dependence of the effective bulk viscosity coefficient given by the expression

$$\zeta = \frac{g_Qm^2\tau_{eq}}{3T} \int_0^\infty \frac{dp}{2\pi^2} \left[ (f_{Q^+,eq} (1 - f_{Q^+,eq}) + f_{Q^-,eq} (1 - f_{Q^-,eq})) \left( \kappa_1 - \frac{p^2}{3(m^2 + p^2)} \right) \right. \left. + (f_{Q^+,eq} (1 - f_{Q^+,eq}) - f_{Q^-,eq} (1 - f_{Q^-,eq})) \frac{\kappa_2}{\sqrt{m^2 + p^2}} \right],$$

where $\kappa_1$ and $\kappa_2$ are defined by the thermodynamic derivatives

$$\kappa_1(T, \mu) = \left( \frac{\partial P_{eq}}{\partial E_{eq}} \right)_{B_{eq}}, \quad \kappa_2(T, \mu) = \frac{1}{3} \left( \frac{\partial P_{eq}}{\partial B_{eq}} \right)_{E_{eq}}.$$
FIG. 9: (Color online) $\mathcal{P}_T/\mathcal{E}$ (upper panels) and $\mathcal{P}_L/\mathcal{P}_T$ (lower panels) for initially oblate-oblate system. Green solid lines correspond to “massless” quarks and classical distribution functions, black dashed lines to the massive quarks and classical distribution functions, while red solid lines are for massive quarks and quantum distributions. Left (right) panels describe the results for $B_0 = 0.001 \text{ fm}^{-3}$ ($B_0 = 1 \text{ fm}^{-3}$).

For a simple fluid with zero baryon density, the coefficient $\kappa_1$ becomes equal to the sound velocity squared. The steps leading to Eq. (90) are described in more detail in Appendix C. The form of (90) agrees with that given in [55] for fermions. There is, however, one important difference between our approach and that of [55]. In Ref. [55] a simple system of fermions is considered and (90) includes the derivatives (91) where only fermionic thermodynamic functions appear. In our case we deal with a mixture and we have checked that (91) should include the total thermodynamic functions being the sums of quark and gluon contributions. Thus, although the bulk viscosity of a quark-gluon mixture is given by the formula known for massive quarks (and $\zeta = 0$ if $m = 0$), the use of the full thermodynamic functions in (91) means that although gluons are considered massless they contribute to the bulk viscosity of
Similarly as in the shear sector, we can see in Fig. 7 that $\zeta_{\text{eff}}(\tau)$ approaches $\zeta(\tau)$, however, the agreement is reached for significantly larger times, $\tau > 2$ fm. This means that the hydrodynamization of the bulk sector is slower and follows the hydrodynamization of the shear sector. Observations that the hydrodynamization in the shear sector may happen before the hydrodynamization in the bulk sector have been done recently in Ref. [59] within the non-conformal models using the gauge/gravity correspondence, where the hydrodynamization in the bulk sector has been dubbed the EoSization process. In this scenario first $P_L$ and $P_T$ tend to a common value $\bar{P} \neq P^{eq}$ and, subsequently, $\bar{P}$ approaches $P^{eq}$, which signals establishing equation of state of the system.

To visualize the importance of the gluon degrees of freedom in expressions (91) for the bulk viscosity of the mixture in Fig. 8 we show the bulk viscosity coefficient $\zeta$ and compare it with the coefficient $\zeta_0$ that has been calculated in the same way as $\zeta$ except that the thermodynamic coefficients $\kappa_1$ and $\kappa_2$ of the former were calculated only for the quark component.

FIG. 10: (Color online) Same as Fig. 9 but for initially prolate-oblate system.
We find that neglecting the gluon contribution in $\kappa_1$ and $\kappa_2$ changes substantially the values of $\zeta$ making it significantly smaller. This finding indicates that gluons, although, massless, contribute to the bulk viscosity of a quark-gluon mixture. The necessary requirement for this effect is, however, that quarks are massive.

3. $P_T/E$ and $P_L/P_T$ ratios

Figures 9, 10, and 11 correspond to Figs. 1, 2, and 3, respectively, and show the time dependence of the ratios $P_T/E$ (upper panels) and $P_L/P_T$ (lower panels). In the case of quarks with a very small mass (green dot-dashed lines) the ratios $P_T/E$ tend to $1/3$ as expected for massless systems approaching local equilibrium. The ratios $P_L/P_T$ in all studied cases tend to unity which again reflects equilibration of the system. Interestingly, the ratios $P_L/P_T$ very weakly depend on the quark mass and the choice of the statistics.
FIG. 12: (Color online) $\mathcal{P}_T/\mathcal{E}$ (upper panels) and $\mathcal{P}_L/\mathcal{P}_T$ (lower panels) for “massless” quarks and classical distribution functions. Green dot-dashed, navy blue dashed, and red solid lines describe the results for the oblate-oblate, prolate-oblate, and prolate-prolate initial conditions. The blue dotted line describes $(\mathcal{P}_L/\mathcal{P}_T)_{\text{NS}}$ obtained from the Navier-Stokes hydrodynamics.

C. Scaling properties

Each panel of Figs. 9, 10, and 11 shows our results obtained for different values of the quark mass and particle statistics but for the same initial anisotropies. In Figs. 12, 13, and 14 we rearrange this information showing in each panel our results obtained for different initial anisotropies, i.e., for oblate-oblate, prolate-oblate, and prolate-prolate initial quark and gluon distributions. Figures 12, 13, and 14 collect the results for different mass and statistics. The most striking feature of our results presented in these figures is that the $\mathcal{P}_L/\mathcal{P}_T$ ratios (shown in lower panels) converge to the same values, although they describe the system evolutions starting from completely different initial conditions.

The origin of this behaviour can be found if we analyse the NS formula for the $\mathcal{P}_L/\mathcal{P}_T$
Let us first consider the massless case where we may neglect the bulk viscosity and write
\[
\left( \frac{p_L}{p_T} \right)_{\text{NS}} = \frac{p^{Q,\text{eq}} - 4\eta_Q/(3\tau) + p^{G,\text{eq}} - 4\eta_G/(3\tau)}{p^{Q,\text{eq}} + 2\eta_Q/(3\tau) + p^{G,\text{eq}} + 2\eta_G/(3\tau)}.
\]
Assuming in addition that the baryon number density is zero, we may use the following relations connecting the shear viscosity with equilibrium pressure \(^7\):
\[
\eta_Q = \frac{4}{5} \tau_{\text{eq}} p^{Q,\text{eq}}, \quad \eta_G = \frac{4}{5} \tau_{\text{eq}} p^{G,\text{eq}}.
\]
It is interesting to note that the coefficient 4/5 is the same for quarks and gluons, hence
\[
\left( \frac{p_L}{p_T} \right)_{\text{NS}} = \frac{1 - 16\tau_{\text{eq}}/(15\tau)}{1 + 8\tau_{\text{eq}}/(15\tau)},
\]
which explains the late-time dependence of \(p_L/p_T\) on the proper time only, observed in panel (c) of Fig. 12. We note that if the relaxation time is inversely proportional to the

\(^7\) See our discussion below Eq. (C19).
FIG. 14: (Color online) Same as Fig. 12 but for massive quarks and quantum statistics.

temperature, Eq. (94) indicates that \((P_L/P_T)_{NS}\) depends on the product of \(\tau\) and \(T\), which is expected for conformal systems and related to the existence of a hydrodynamic attractor for such systems [31–36]. It turns out that the inclusion of the finite mass and baryon chemical potential (with the values studied in this work) affects very little Eqs. (93) connecting the shear viscosity with pressure. The main difference is that the coefficient 4/5 is slightly changed. It should be replaced by an effective value obtained for the studied range of \(T\) and \(\mu\).

To analyse the \((P_L/P_T)_{NS}\) ratio in a general case in Fig. 15 we plot it as a function of two variables, \(\tau_{eq}/\tau\) and \(m/T\), for a fixed value of \(\mu\). The left panel of Fig. 15 shows the contour plot of \((P_L/P_T)_{NS}\) in the case where quantum statistics are used and \(\mu = 0\). The fact that the contour (red dashed) lines have horizontal shapes indicates that \((P_L/P_T)_{NS}\) depends effectively only on \(\tau_{eq}/\tau\) (except for the region where \(\tau \approx \tau_{eq}\) and \(T \approx m/5\)). The red dashed lines overlap with solid black lines corresponding to the result for the case of classical statistics. It shows that quantum statistics have negligible effect on \((P_L/P_T)_{NS}\) in
FIG. 15: (Color online) Contour plots of $(P_L/P_T)_{\text{NS}}$ obtained for the Navier-Stokes hydrodynamics for $\mu = 0$ (a) and $\mu/T = 2$ (b). In the two cases quarks and gluons are described by quantum statistics. The solid black lines together with the contour shading represent the classical baryon-free system.

The studied, rather broad range of $\tau_{eq}/\tau$ and $m/T$. These observations explain similarities of the close-to-equilibrium behavior of $(P_L/P_T)_{\text{NS}}$ in the left panels of Figs. 9, 10, and 11. The right panel of Fig. 15 shows the contour plot of $(P_L/P_T)_{\text{NS}}$ for $\mu/T = 2$. In this case we find again a weak dependence on $m/T$ as compared to the case of classical statistics and $\mu = 0$ represented by the solid black lines. Again this helps to understand the similarities of the right and left panels of Figs. 9, 10, and 11.

D. Remarks on non-conformal attractor

In a very recent paper [37] it has been suggested by Romatschke to look for attractor behaviour by studying the quantities

$$A_1 = \frac{\tau d\mathcal{E}}{(\mathcal{E} + P_{eq})d\tau} \quad (95)$$
FIG. 16: (Color online) The quantity $A_1$ plotted as a function of $\Gamma$ for three different initial anisotropies, finite quark mass, and quantum statistics.

and

$$A_2 = \frac{2\mathcal{P}_T + \mathcal{P}_L - 3\mathcal{P}_{eq}}{\zeta T}$$  \hspace{1cm} (96)
as functions of the variable

\[ \Gamma = \tau \left[ \frac{4}{3} \frac{\eta}{\E + \P_{eq}} + \frac{\zeta}{\E + \P_{eq}} \right]^{-1}. \] (97)

Note that in Eqs. (95)–(97) we used boost invariance to simplify our notation.

In Fig. 16 we show the function \( A_1(\Gamma) \) obtained for three different initial anisotropies studied in this work. To get the connection with [37] we consider the case with negligible baryon number density. Otherwise, we include the finite mass of quarks and quantum statistics. Figure 16 shows that the lines corresponding to three different initial conditions converge and later approach the Navier-Stokes line. This observation supports the existence of a non-conformal attractor for \( A_1 \) in our system.

Figure 17 shows similar results as Fig. 16 but for \( A_2(\Gamma) \). In this case, the lines corresponding to different initial conditions converge with each other only in the NS regime. Hence, our present results are insufficient to demonstrate the existence of an attractor for \( A_2 \). Further study of this behaviour is planned for our future investigations.

X. SUMMARY AND CONCLUSIONS

In this work we have solved a system of coupled kinetic equations for quarks, antiquarks and gluons in the relaxation time approximation. We have generalised previous results by including: the finite quark mass, the quantum statistics for both quarks and gluons, and the finite baryon number. We have compared the results of the numerical calculations with the first-order hydrodynamic calculations to demonstrate the hydrodynamization process. We have found that equalisation of the longitudinal and transverse pressures takes place earlier than equalisation of the average and equilibrium pressures. We have determined the shear and bulk viscosities of a mixture and find that the shear viscosity is a sum of the quark and gluon shear viscosities, while the bulk viscosity of a mixture is given by the formula known for a massive quark gas. However, the bulk viscosity depends on thermodynamic coefficients characterising the whole mixture rather than quarks alone, which means that massless gluon do contribute to the bulk viscosity (if quarks are massive).
Acknowledgments

We thank Paul Romatschke, Michal Spalinski, and Michael Strickland for clarifying discussion of our preliminary results during the Initial Stages 2017 conference in Krakow. W.F. and R.R. were supported in part by the Polish National Science Center Grant No. 2016/23/B/ST2/00717.

Appendix A: Generalized thermodynamic functions

In this section we present explicit expressions for various physical quantities such as the particle and energy densities or the transverse and longitudinal pressures. These expressions are obtained with the use of different distribution functions which not necessarily correspond to local equilibrium. Thus, we call them generalised thermodynamic functions — in local equilibrium they become standard thermodynamic functions satisfying well known thermodynamic identities. We start with the anisotropic RS distributions, as other cases can be easily worked out if the results for the RS distributions are known.

1. Anisotropic distributions

The forms of the generalised thermodynamic functions for anisotropic distributions are given by the following integrals:

\[
\mathcal{N}^{s,a} \equiv n_U^{s,a} = k_s \int dP \ (p \cdot U) f_{s,a} \left[ p \cdot U, p \cdot Z \right],
\]

(A1)

\[
\mathcal{E}^{s,a} \equiv t_{UU}^{s,a} = k_s \int dP \ (p \cdot U)^2 f_{s,a} \left[ p \cdot U, p \cdot Z \right],
\]

(A2)

\[
\mathcal{P}_T^{s,a} \equiv t_{AA}^{s,a} = k_s \int dP \ (p \cdot X)^2 f_{s,a} \left[ p \cdot U, p \cdot Z \right] \quad (A \neq U, Z)
\]

\[= k_s \int dP \ (p \cdot Y)^2 f_{s,a} \left[ p \cdot U, p \cdot Z \right] \]

\[= -\frac{k_s}{2} \int dP \ (p \cdot \Delta T \cdot p) f_{s,a} \left[ p \cdot U, p \cdot Z \right],
\]

(A3)

\[
\mathcal{P}_L^{s,a} \equiv t_{ZZ}^{s,a} = k_s \int dP \ (p \cdot Z)^2 f_{s,a} \left[ p \cdot U, p \cdot Z \right].
\]

(A4)
The explicit calculations lead to the following expressions for quarks and antiquarks

\[ \mathcal{N}^{Q\pm,a} = 4\pi k_Q \Lambda_Q^3 \tilde{H}_N^+ \left( \frac{1}{\sqrt{1 + \xi_Q}}, \frac{m}{\Lambda_Q}, \mp \frac{\lambda}{\Lambda_Q} \right), \]  
(A5)

\[ \mathcal{E}^{Q\pm,a} = 2\pi k_Q \Lambda_Q^4 \tilde{H}_N^+ \left( \frac{1}{\sqrt{1 + \xi_Q}}, \frac{m}{\Lambda_Q}, \mp \frac{\lambda}{\Lambda_Q} \right), \]  
(A6)

\[ \mathcal{P}_{T}^{Q\pm,a} = \pi k_Q \Lambda_Q^4 \tilde{H}_T^+ \left( \frac{1}{\sqrt{1 + \xi_Q}}, \frac{m}{\Lambda_Q}, \mp \frac{\lambda}{\Lambda_Q} \right), \]  
(A7)

\[ \mathcal{P}_{L}^{Q\pm,a} = 2\pi k_Q \Lambda_Q^4 \tilde{H}_L^+ \left( \frac{1}{\sqrt{1 + \xi_Q}}, \frac{m}{\Lambda_Q}, \mp \frac{\lambda}{\Lambda_Q} \right), \]  
(A8)

where functions \( \tilde{H} \) are defined by the integrals:

\[ \tilde{H}_N^\pm (a, y, z) \equiv \int_0^\infty r^2 dr h_{eq}^\pm \left( \sqrt{r^2 + y^2 + z} \right) a, \]  
(A9)

\[ \tilde{H}^\pm (a, y, z) \equiv \int_0^\infty r^3 dr h_{eq}^\pm \left( \sqrt{r^2 + y^2 + z} \right) H_2 \left( a, \frac{y}{r} \right), \]  

\[ \tilde{H}_T^\pm (a, y, z) \equiv \int_0^\infty r^3 dr h_{eq}^\pm \left( \sqrt{r^2 + y^2 + z} \right) H_{2T} \left( a, \frac{y}{r} \right), \]  

\[ \tilde{H}_L^\pm (a, y, z) \equiv \int_0^\infty r^3 dr h_{eq}^\pm \left( \sqrt{r^2 + y^2 + z} \right) H_{2L} \left( a, \frac{y}{r} \right), \]  

and the functions \( H_2(a, b) \) were introduced in [4]:

\[ H_2 (a, b) \equiv a \int_0^\pi d\varphi \sin \varphi \sqrt{a^2 \cos^2 \varphi + \sin^2 \varphi + b^2}, \]  
(A10)

\[ H_{2T} (a, b) \equiv a \int_0^\pi d\varphi \frac{\sin^3 \varphi}{\sqrt{a^2 \cos^2 \varphi + \sin^2 \varphi + b^2}}, \]

\[ H_{2L} (a, b) \equiv a^3 \int_0^\pi d\varphi \frac{\sin \varphi \cos^2 \varphi}{\sqrt{a^2 \cos^2 \varphi + \sin^2 \varphi + b^2}}. \]
With $b = 0$ the functions $H_2(a, b)$ reduce to the functions $H(a), H_L(a)$ and $H_T(a)$ used in [2]. The integrals in (A10) are analytic [4]:

\[
H_2(a, b) = \frac{a}{\sqrt{a^2 - 1}} \left( (1 + b^2) \tanh^{-1} \sqrt{\frac{a^2 - 1}{a^2 + b^2}} + \sqrt{(a^2 - 1)(a^2 + b^2)} \right),
\]

(A11)

\[
H_{2T}(a, b) = \frac{a}{(a^2 - 1)^{3/2}} \left( (b^2 + 2a^2 - 1) \tanh^{-1} \sqrt{\frac{a^2 - 1}{a^2 + b^2}} - \sqrt{(a^2 - 1)(a^2 + b^2)} \right),
\]

(A12)

\[
H_{2L}(a, b) = \frac{a^3}{(a^2 - 1)^{3/2}} \left( -(1 + b^2) \tanh^{-1} \sqrt{\frac{a^2 - 1}{a^2 + b^2}} + \sqrt{(a^2 - 1)(a^2 + b^2)} \right).
\]

(A13)

For gluons one has:

\[
N^{G,a} = 4\pi k_G \Lambda_G^3 \tilde{H}_N^- \left( \frac{1}{\sqrt{1 + \xi_G}}, 0, 0 \right) = 8\pi \zeta(3) k_G \frac{\Lambda_G^3}{\sqrt{1 + \xi_G}},
\]

(A14)

\[
\mathcal{E}^{G,a} = 2\pi k_G \Lambda_G^4 \tilde{H}^- \left( \frac{1}{\sqrt{1 + \xi_G}}, 0, 0 \right) = \frac{2\pi^5}{15} k_G \Lambda_G^4 \mathcal{H} \left( \frac{1}{\sqrt{1 + \xi_G}} \right),
\]

(A15)

\[
\mathcal{P}^{G,a}_T = \pi k_G \Lambda_G^4 \tilde{H}_T^- \left( \frac{1}{\sqrt{1 + \xi_G}}, 0, 0 \right) = \frac{\pi^5}{15} k_G \Lambda_G^4 \mathcal{H}_T \left( \frac{1}{\sqrt{1 + \xi_G}} \right),
\]

(A16)

\[
\mathcal{P}^{G,a}_L = 2\pi k_G \Lambda_G^4 \tilde{H}_L^- \left( \frac{1}{\sqrt{1 + \xi_G}}, 0, 0 \right) = \frac{2\pi^5}{15} k_G \Lambda_G^4 \mathcal{H}_L \left( \frac{1}{\sqrt{1 + \xi_G}} \right),
\]

(A17)

where $\zeta$ is the Riemann zeta function (the coefficient $\zeta(3)$ is known as Apéry’s constant).

The expressions on the right-hand sides of Eqs. (A14)-(A17) hold for the Bose-Einstein statistics. Note that in the case of massless gluons the integrals (A10) are done for $b = 0$ and can be factorized in Eqs. (A9).

It is useful to notice that the functions $H_2$ and $H_{2L}$ are related by the expression

\[
\frac{\partial H_2(a, b)}{\partial a} = \frac{H_2(a, b) + H_{2L}(a, b)}{a},
\]

(A18)

hence, we also have

\[
\frac{\partial \tilde{H}^\pm(a, y, z)}{\partial a} = \frac{\tilde{H}^\pm(a, y, z) + \tilde{H}^\pm(a, y, z)}{a}.
\]

(A19)

We can use (A19) to derive (83) from (81).

We close this section with the formula for the baryon number density valid for anisotropic RS systems

\[
B^a = \frac{N^{Q_+ a} - N^{Q_- a}}{3} = \frac{16\pi k_Q \Lambda_Q^3}{3 \sqrt{1 + \xi_Q}} \sinh \left( \frac{\lambda}{\Lambda_Q} \right) \mathcal{H}_B \left( \frac{m}{\Lambda_Q}, \frac{\lambda}{\Lambda_Q} \right),
\]

(A20)

where

\[
\mathcal{H}_B(y, z) \equiv \frac{1}{4} \int_0^\infty r^2 dr \left[ \frac{1}{\cosh \sqrt{r^2 + y^2 + \cosh z}} \right].
\]

(A21)
2. Isotropic distributions

The forms of the thermodynamic functions for the equilibrium state are commonly known, nevertheless, we quote them here for completeness. They are given by the formulas

\[ \mathcal{N}^{s,\text{eq}} \equiv n_{U}^{s,\text{eq}} = k_{s} \int dP \ (p \cdot U) f_{s,\text{eq}}(p \cdot U), \] (A22)

\[ \mathcal{E}^{s,\text{eq}} \equiv t_{UU}^{s,\text{eq}} = k_{s} \int dP \ (p \cdot U)^{2} f_{s,\text{eq}}(p \cdot U), \] (A23)

\[ \mathcal{P}^{s,\text{eq}} \equiv t_{AA}^{s,\text{eq}} = k_{s} \int dP \ (p \cdot A)^{2} f_{s,\text{eq}}(p \cdot U) \]
\[ = -\frac{k_{s}}{3} \int dP \ (p \cdot \Delta \cdot p) f_{s,\text{eq}}(p \cdot U), \quad (A \neq U). \] (A24)

Their explicit forms for quarks and anti-quarks may be obtained from Eqs. (A5)–(A8) as a special case of \( \xi_{s} \rightarrow 0, \Lambda_{s} \rightarrow T, \) and \( \lambda_{s} \rightarrow \mu, \)

\[ \mathcal{N}^{Q^{\pm},\text{eq}} = 4\pi k_{Q}T^{3}\mathcal{H}_{N}^{\pm}(1, \frac{m}{T}, \mp \frac{\mu}{T}), \] (A25)

\[ \mathcal{E}^{Q^{\pm},\text{eq}} = 2\pi k_{Q}T^{4}\mathcal{H}_{T}^{\pm}(1, \frac{m}{T}, \mp \frac{\mu}{T}), \] (A26)

\[ \mathcal{P}_{T}^{Q^{\pm},\text{eq}} = \pi k_{Q}T^{4}\mathcal{H}_{T}^{\pm}(1, \frac{m}{T}, \mp \frac{\mu}{T}), \] (A27)

\[ \mathcal{P}_{L}^{Q^{\pm},\text{eq}} = 2\pi k_{Q}T^{4}\mathcal{H}_{L}^{\pm}(1, \frac{m}{T}, \mp \frac{\mu}{T}). \] (A28)

Note that \( \mathcal{H}_{2L}(1, b) = 2/(3\sqrt{1+b^{2}}) \) and \( \mathcal{H}_{2T}(1, b) = 4/(3\sqrt{1+b^{2}}) \) which means that \( \mathcal{P}_{L}^{Q^{\pm},\text{eq}} = \mathcal{P}_{L}^{Q^{\pm},\text{eq}} \equiv \mathcal{P}^{Q^{\pm},\text{eq}}, \) as expected for the isotropic state. Analogous results may be obtained for gluons

\[ \mathcal{N}^{G,\text{eq}} = 4\pi k_{G}T^{3}\mathcal{H}_{N}^{\pm}(1, 0, 0) = 8\pi \zeta(3)k_{G}T^{3}, \] (A29)

\[ \mathcal{E}^{G,\text{eq}} = 2\pi k_{G}T^{4}\mathcal{H}_{T}^{\pm}(1, 0, 0) = \frac{4\pi^{5}}{15}k_{G}T^{4}, \] (A30)

\[ \mathcal{P}_{T}^{G,\text{eq}} = \pi k_{G}T^{4}\mathcal{H}_{T}^{\pm}(1, 0, 0) = \frac{4\pi^{5}}{45}k_{G}T^{4}, \] (A31)

\[ \mathcal{P}_{L}^{G,\text{eq}} = 2\pi k_{G}T^{4}\mathcal{H}_{L}^{\pm}(1, 0, 0) = \frac{4\pi^{5}}{45}k_{G}T^{4}, \] (A32)

where to get the last expressions on the right-hand sides we again assumed the Bose-Einstein statistics. Here, similarly as for quarks \( \mathcal{P}_{T}^{G,\text{eq}} = \mathcal{P}_{L}^{G,\text{eq}} \equiv \mathcal{P}^{G,\text{eq}}. \) Similarly to anisotropic case the baryon number density is

\[ B^{\text{eq}} = \frac{N^{Q^{+},\text{eq}} - N^{Q^{-},\text{eq}}}{3} = \frac{16\pi k_{Q}T^{3}}{3} \sinh \left( \frac{\mu}{T} \right) \mathcal{H}_{B}\left( \frac{m}{T}, \frac{\mu}{T} \right). \] (A33)
3. Exact solution of the kinetic equations

For the solutions of Eqs. (57) of the form (61) the thermodynamic variables have the forms

\[ N^s = k_s \int dP \ (p \cdot U) \, f_s \left[ p \cdot U, p \cdot Z \right], \]
\[ E^s = k_s \int dP \ (p \cdot U)^2 \, f_s \left[ p \cdot U, p \cdot Z \right], \] (A34)
\[ P^s_T = k_s \int dP \ (p \cdot A)^2 \, f_s \left[ p \cdot U, p \cdot Z \right] \quad (A \neq U, Z), \]
\[ P^s_L = k_s \int dP \ (p \cdot Z)^2 \, f_s \left[ p \cdot U, p \cdot Z \right]. \]

Using above definitions and repeating the calculation from Sec. A 1, gives

\[ N^{Q\pm} = 4\pi k_Q \left[ (\Lambda_Q^0)^3 \tilde{H}_N^+ \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_Q^0}}, \frac{m}{\Lambda_Q^0}, \pm \frac{\lambda^0}{\Lambda_Q^0} \right) D(\tau, \tau_0) \right. \]
\[ \left. + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} \, D(\tau, \tau') \, (T')^3 \tilde{H}_N^+ \left( \frac{\tau'}{\tau}, \frac{m}{T'}, \pm \frac{\mu'}{T'} \right) \right], \]
\[ E^{Q\pm} = 2\pi k_Q \left[ (\Lambda_Q^0)^4 \tilde{H}^+ \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_Q^0}}, \frac{m}{\Lambda_Q^0}, \pm \frac{\lambda^0}{\Lambda_Q^0} \right) D(\tau, \tau_0) \right. \]
\[ \left. + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} \, D(\tau, \tau') \, (T')^4 \tilde{H}^+ \left( \frac{\tau'}{\tau}, \frac{m}{T'}, \pm \frac{\mu'}{T'} \right) \right], \]
\[ P^{Q\pm}_T = \pi k_Q \left[ (\Lambda_Q^0)^4 \tilde{H}_T^+ \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_Q^0}}, \frac{m}{\Lambda_Q^0}, \pm \frac{\lambda^0}{\Lambda_Q^0} \right) D(\tau, \tau_0) \right. \]
\[ \left. + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} \, D(\tau, \tau') \, (T')^4 \tilde{H}_T^+ \left( \frac{\tau'}{\tau}, \frac{m}{T'}, \pm \frac{\mu'}{T'} \right) \right], \]
\[ P^{Q\pm}_L = 2\pi k_Q \left[ (\Lambda_Q^0)^4 \tilde{H}_L^+ \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_Q^0}}, \frac{m}{\Lambda_Q^0}, \pm \frac{\lambda^0}{\Lambda_Q^0} \right) D(\tau, \tau_0) \right. \]
\[ \left. + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} \, D(\tau, \tau') \, (T')^4 \tilde{H}_L^+ \left( \frac{\tau'}{\tau}, \frac{m}{T'}, \pm \frac{\mu'}{T'} \right) \right], \]
for quarks and

$$N^G = 4\pi k_G \left[ (\Lambda_G^0)^3 \tilde{H}_N^- \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_0^G}}, 0, 0 \right) D(\tau, \tau_0) + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} D(\tau, \tau') (T')^3 \tilde{H}_N^- \left( \frac{\tau'}{\tau}, 0, 0 \right) \right] ,$$

(A39)

$$E^G = 2\pi k_G \left[ (\Lambda_G^0)^4 \tilde{H}^- \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_0^G}}, 0, 0 \right) D(\tau, \tau_0) + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} D(\tau, \tau') (T')^4 \tilde{H}^- \left( \frac{\tau'}{\tau}, 0, 0 \right) \right] ,$$

(A40)

$$P_T^G = \pi k_G \left[ (\Lambda_G^0)^4 \tilde{H}_T^- \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_0^G}}, 0, 0 \right) D(\tau, \tau_0) + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} D(\tau, \tau') (T')^4 \tilde{H}_T^- \left( \frac{\tau'}{\tau}, 0, 0 \right) \right] ,$$

(A41)

$$P_L^G = 2\pi k_G \left[ (\Lambda_G^0)^4 \tilde{H}_L^- \left( \frac{\tau_0}{\tau \sqrt{1 + \xi_0^G}}, 0, 0 \right) D(\tau, \tau_0) + \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} D(\tau, \tau') (T')^4 \tilde{H}_L^- \left( \frac{\tau'}{\tau}, 0, 0 \right) \right] ,$$

(A42)

for gluons. We define the baryon number density for the exact solution of the kinetic equation as follows

$$B = \frac{16\pi k_Q}{3} \left[ \frac{\tau_0 (\Lambda_Q^0)^3}{\tau \sqrt{1 + \xi_Q^0}} \sinh \left( \frac{\lambda_0^0 \Lambda_Q^0}{\Lambda_Q^0} \right) \mathcal{H}_B \left( \frac{m}{\Lambda_Q^0}, \frac{\lambda^0}{\Lambda_Q^0} \right) D(\tau, \tau_0) \right]$$

$$+ \int_{\tau_0}^{\tau} \frac{d\tau'}{\tau_{eq}'} D(\tau, \tau') \left( \frac{T'}{\tau} \right)^3 \sinh \left( \frac{\mu'}{T'} \right) \mathcal{H}_B \left( \frac{m}{T'}, \frac{\mu'}{T'} \right) \right] .$$

(A43)

Appendix B: Navier-Stokes hydrodynamics

The results of our kinetic-theory calculations are compared with the viscous hydrodynamic results obtained by solving the Navier-Stokes (NS) hydrodynamic equations. The latter have the form

$$\frac{d}{d\tau} (\mathcal{E}_Q,eq + \mathcal{E}_G,eq) = - \mathcal{E}_Q,eq + \mathcal{E}_G,eq + \mathcal{P}_Q,eq + \mathcal{P}_G,eq + \Pi_{NS} - \pi_{NS} ,$$

(B1)

$$\frac{dB^eq}{d\tau} + \frac{B^eq}{\tau} = 0 .$$

(B2)
Here $\mathcal{E}^{Q,eq} = \mathcal{E}^{Q+},eq + \mathcal{E}^{Q-},eq$ is the equilibrium energy density of quarks and antiquarks, $\mathcal{P}^{Q,eq} = \mathcal{P}^{Q+},eq + \mathcal{P}^{Q-},eq$ is the equilibrium pressure of quarks and antiquarks, $\Pi_{NS}$ is the bulk pressure, and $\pi_{NS}$ is the shear pressure (both used in the close-to-equilibrium limit). All the functions appearing in (B1) and (B2) depend on $T$ and $\mu$, hence Eqs. (B1) and (B2) are two coupled equations that can be used to determine $T(\tau)$ and $\mu(\tau)$. One can easily notice that Eq. (B1) may be written in the form of Eq. (83) once we identify

$$\mathcal{P}_L = \mathcal{P}^{eq} - \pi_{NS} + \Pi_{NS},$$  \hspace{1cm} (B3)$$ $$\mathcal{P}_T = \mathcal{P}^{eq} + \frac{1}{2} \pi_{NS} + \Pi_{NS},$$

where $\mathcal{P}^{eq} = \mathcal{P}^{Q,eq} + \mathcal{P}^{G,eq}$. Within NS approach, the shear and bulk pressures are expressed by the kinetic coefficients $\eta$ and $\zeta$,

$$\pi_{NS} = \frac{4\eta}{3\tau} = \frac{4(\eta_Q + \eta_G)}{3\tau},$$ \hspace{1cm} (B4)$$ $$\Pi_{NS} = -\frac{\zeta}{\tau}.$$ \hspace{1cm} (B5)

The expressions for $\eta_Q$, $\eta_G$, and $\zeta$ are given by Eqs. (86), (87), and (90).

For the moment let us denote $T(\tau)$ and $\mu(\tau)$ obtained from the kinetic theory as $T_{KT}(\tau)$ and $\mu_{KT}(\tau)$, while those obtained from the NS hydrodynamics as $T_{NS}(\tau)$ and $\mu_{NS}(\tau)$. We expect that $T_{KT}(\tau)$ and $\mu_{KT}(\tau)$ agree well with $T_{NS}(\tau)$ and $\mu_{NS}(\tau)$ in the late stages of the evolution, when the system approaches local equilibrium. To check this behaviour we choose such initial conditions for hydrodynamic equations (B1) and (B2) that for the final time $\tau = \tau_f$ we match the temperature and chemical potential in the two approaches: $T_{NS}(\tau_f) = T_{KT}(\tau_f)$, $\mu_{NS}(\tau_f) = \mu_{KT}(\tau_f)$. Then, we check if the functions $T_{NS}(\tau)$ and $\mu_{NS}(\tau)$ smoothly approach $T_{KT}(\tau)$ and $\mu_{KT}(\tau)$ if $\tau \to \tau_f$. By neglecting the bulk and shear pressures in (B1) we can also make comparison with perfect fluid hydrodynamics and check if the system approaches local equilibrium.

### Appendix C: Shear and Bulk viscosities for mixtures

In this section we present details of our method used to calculate the shear and bulk viscosity coefficients for a quark-gluon mixture. We follow the treatment of Refs. [60, 61], where the
bulk viscosity was obtained for the Gribov-Zwanziger plasma. Analyzing a boost-invariant system, we deal with a simple structure of hydrodynamic equations, which facilitates the calculations.

1. Landau matching conditions in the case of boost invariant geometry

In the first-order gradient expansion, the non-equilibrium corrections to the equilibrium distribution function have the form

\[ \delta f_Q^\pm = -\tau_{eq} \frac{\partial f_{Q^\pm,eq}}{\partial \tau}, \quad \delta f_G = -\tau_{eq} \frac{\partial f_{G,eq}}{\partial \tau}. \] (C1)

Using the form of \( f_{Q^\pm,eq} \) and \( f_{G,eq} \) for boost-invariant geometry we find

\[ \delta f_Q^\pm = -\tau_{eq} f_{Q^\pm,eq} (1 - f_{Q^\pm,eq}) \left[ \frac{w^2}{v^2 T^\pm} \pm \left( \frac{v}{\tau} \mp \mu \right) \frac{d \ln T}{T d\tau} \right], \] (C2)

\[ \delta f_G = -\tau_{eq} f_{G,eq} (1 + f_{G,eq}) \left[ \frac{w^2}{v^2 T^G} + \frac{v}{\tau} \frac{d \ln T}{T d\tau} \right]. \] (C3)

The Landau matching conditions for the energy and momentum read

\[ \int \frac{dwd^2p_T}{v} \frac{v^2}{\tau^2} f_{3S} \left[ k_Q (\delta f_Q^+ + \delta f_Q^-) + k_G \delta f_G \right] = 0, \] (C4)

\[ \int \frac{dwd^2p_T}{v} \frac{v^2}{3\tau^2} f_{2S} \left[ k_Q (\delta f_Q^+ - \delta f_Q^-) \right] = 0. \] (C5)

Using (C2) and (C3) we rewrite (C4) and (C5) as

\[ \int \frac{dwd^2p_T}{v} \frac{v^2}{\tau^2} f_{3S} \left[ k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) + f_{Q^-,eq} (1 - f_{Q^-,eq}) \right] + k_G f_{G,eq} (1 + f_{G,eq}) \right] \]

\[ + \int \frac{dwd^2p_T}{v} \frac{v^2}{\tau^2} f_{2D} \left[ k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) - f_{Q^-,eq} (1 - f_{Q^-,eq}) \right] \right] \]

\[ + \int \frac{dwd^2p_T}{v} \frac{v^2}{\tau^2} f_{2D} \left[ k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) \right] \right] \]

\[ + \int \frac{dwd^2p_T}{v} \frac{v^2}{\tau^2} f_{2D} \left[ k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) \right] \right] = 0, \] (C6)

and

\[ \int \frac{dwd^2p_T}{v} \frac{v^2}{\tau^2} f_{2D} \left[ k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) - f_{Q^-,eq} (1 - f_{Q^-,eq}) \right] \right] \]

\[ + \int \frac{dwd^2p_T}{v} \frac{v^2}{\tau^2} f_{2D} \left[ k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) \right] \right] \]

\[ + \int \frac{dwd^2p_T}{v} \frac{v^2}{\tau^2} f_{2D} \left[ k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) \right] \right] = 0, \] (C7)

where

\[ f_{3S} = k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) + f_{Q^-,eq} (1 - f_{Q^-,eq}) \right] + k_G f_{G,eq} (1 + f_{G,eq}), \]

\[ f_{2S} = k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) + f_{Q^-,eq} (1 - f_{Q^-,eq}) \right], \]

\[ f_{2D} = k_Q \left[ f_{Q^+,eq} (1 - f_{Q^+,eq}) - f_{Q^-,eq} (1 - f_{Q^-,eq}) \right]. \] (C8)
By introducing the “averaged” values defined as

\[ \langle \ldots \rangle_\alpha \equiv \int \frac{dw^2 p_T}{v} \ldots f_\alpha, \quad \text{(C9)} \]

where \( \alpha = 3S, 2S, 2D \), we rewrite (C6) and (C7) in the compact form

\[ \langle w^2 \rangle_{3S} + \langle v^2 \rangle_{2S} \frac{d\ln T}{d\ln \tau} + \langle v \rangle_{2D} \tau^2 T \frac{d}{d\tau} \left( \frac{\mu}{T} \right) = 0, \]

\[ \langle \frac{w^2}{v} \rangle_{2D} + \langle v \rangle_{2D} \frac{d\ln T}{d\ln \tau} + \langle 1 \rangle_{2S} \tau^2 T \frac{d}{d\tau} \left( \frac{\mu}{T} \right) = 0. \quad \text{(C10)} \]

To proceed further it is convenient to introduce the notation

\[ A = \langle w^2 \rangle_{3S}, \quad B = \langle v^2 \rangle_{3S}, \quad C = \langle v \rangle_{2D}, \quad D = \langle \frac{w^2}{v} \rangle_{2D}, \quad E = \langle 1 \rangle_{2S}. \quad \text{(C11)} \]

Then, we find the proper-time derivatives of \( T \) and \( \mu/T \) expressed by the coefficients (C11)

\[ \frac{d\ln T}{d\ln \tau} = \frac{AE - CD}{C^2 - BE}, \quad \tau^2 T \frac{d}{d\tau} \left( \frac{\mu}{T} \right) = \frac{DB - AC}{C^2 - BE}. \quad \text{(C12)} \]

The coefficients (C11) can be used also to express various thermodynamic derivatives. After straightforward calculations, where \( T \) and \( \mu \) are treated as independent thermodynamic variables, we find

\[ \frac{\partial P_{eq}}{\partial T} = \frac{\partial P^{Q,+}_{eq}}{\partial T} + \frac{\partial P^{Q,-}_{eq}}{\partial T} + \frac{\partial P^{G,eq}}{\partial T} = \frac{A}{\tau^3 T^2} - \frac{D\mu}{\tau^2 T^2}, \]

\[ \frac{\partial P_{eq}}{\partial \mu} = \frac{\partial P^{Q,+}_{eq}}{\partial \mu} + \frac{\partial P^{Q,-}_{eq}}{\partial \mu} = \frac{D}{\tau^2 T}, \]

\[ \frac{\partial \mathcal{E}_{eq}}{\partial T} = \frac{\partial \mathcal{E}^{Q,+}_{eq}}{\partial T} + \frac{\partial \mathcal{E}^{Q,-}_{eq}}{\partial T} + \frac{\partial \mathcal{E}^{G,eq}}{\partial T} = \frac{B}{\tau^3 T^2} - \frac{C\mu}{\tau^2 T^2}, \]

\[ \frac{\partial \mathcal{E}_{eq}}{\partial \mu} = \frac{\partial \mathcal{E}^{Q,+}_{eq}}{\partial \mu} + \frac{\partial \mathcal{E}^{Q,-}_{eq}}{\partial \mu} = \frac{C}{\tau^2 T}, \]

\[ \frac{\partial B_{eq}}{\partial T} = \frac{C}{3\tau^2 T^2} - \frac{E\mu}{3\tau T^3}, \quad \frac{\partial \mathcal{B}_{eq}}{\partial T} = \frac{E\mu}{3\tau T^3}. \quad \text{(C13)} \]

Using (C13) we find that

\[ \kappa_1(T, \mu) = \left( \frac{\partial P_{eq}}{\partial \mathcal{E}_{eq}} \right)_{\mathcal{B}_{eq}} = \frac{1}{3} \frac{\partial (\mathcal{P}_{eq}, \mathcal{B}_{eq})}{\partial (\mathcal{E}_{eq}, \mathcal{B}_{eq})} = -\frac{AE - CD}{C^2 - BE} = -\frac{d\ln T}{d\ln \tau}, \]

\[ \kappa_2(T, \mu) = \frac{1}{3} \left( \frac{\partial P_{eq}}{\partial \mathcal{B}_{eq}} \right)_{\mathcal{E}_{eq}} = \frac{1}{3} \frac{\partial (\mathcal{P}_{eq}, \mathcal{E}_{eq})}{\partial (\mathcal{B}_{eq}, \mathcal{E}_{eq})} = -\frac{DB - AC}{\tau(C^2 - BE)} = -\tau T \frac{d}{d\tau} \left( \frac{\mu}{T} \right). \quad \text{(C14)} \]
2. Shear viscosity

The shear viscosity can be obtained from the formula \( \eta = \tau (P_T - P_L)_{NS}/2 \), which in close-to-equilibrium situations leads to the expression

\[
\eta = \frac{\tau}{2} \frac{d^3 p}{E_p} \left[ \left( \frac{p_x^2}{2} - \frac{w^2}{\tau^2} \right) \int_0^\pi \sin \theta d\theta \left( \frac{\sin^2 \theta}{2} - \cos^2 \theta \right) \cos^2 \theta \right] f_{3S},
\]

where the terms containing derivatives of \( T \) and \( \mu \) dropped out again due to symmetry reasons. Equation (C16) can be rewritten as

\[
\eta = -\frac{\tau_{eq}}{2} \frac{d^3 p}{E_p} \left[ \left( \frac{p_x^2}{2} - \frac{w^2}{\tau^2} \right) \frac{w^2}{v_T T} \right] f_{3S},
\]

which leads to Eqs. (85), (86) and (87).

For massless quarks, Eq. (86) gives \( \eta_Q = 7g_Q\pi^2 T^4 \tau_{eq}/450 \) and \( \eta_Q = 8g_Q T^4 \tau_{eq}/(5\pi^2) \) for Fermi-Dirac and Boltzmann statistics, respectively. The corresponding values of pressure are: \( P_{Q,eq} = 7g_Q\pi^2 T^4/360 \) and \( P_{Q,eq} = 2g_Q T^4/\pi^2 \), hence, for the two statistics we find \( \eta_Q = 4P_{Q,eq}/5 \). In the similar way, from (87) we find for massless gluons: \( \eta_G = 2g_G\pi^2 T^4 \tau_{eq}/225 \) and \( \eta_G = 4g_G T^4 \tau_{eq}/(5\pi^2) \) for Bose-Einstein and Boltzmann statistics. The corresponding pressures are: \( P_{G,eq} = g_G\pi^2 T^4/90 \) and \( P_{G,eq} = g_G T^4/\pi^2 \), which gives again \( \eta_G = 4P_{G,eq}/5 \).

3. Bulk viscosity

The bulk pressure is the difference between the average exact pressure, \( (P_L + 2P_T)/3 \), in the system and the reference equilibrium pressure, \( P_{eq} \). Close to local equilibrium, it can
be defined by the following formula

$$\Pi_{NS} = \frac{1}{3} (PL + 2PT - 3P^\text{eq})_{NS}$$

$$= \frac{1}{3} \int \frac{dwd^2pT}{v} \left[ \left( \frac{w^2}{\tau^2} + p^2_T \right) \left[ kQ(f_{Q+,eq} + f_{Q-,eq} + \delta f_{Q+} + \delta f_{Q-} + kG(f_{G,eq} + \delta f_G) \right] \right.$$  

$$\left. - 3 \frac{w^2}{\tau^2} \left[ kQ(f_{Q+,eq} + f_{Q-,eq} + \delta f_{Q-}) + kGf_{G,eq} \right] \right]$$

$$= \frac{1}{3} \int \frac{dwd^2pT}{v} \left[ \left( \frac{w^2}{\tau^2} + p^2_T \right) \left[ kQ(\delta f_{Q+} + \delta f_{Q-}) + kG\delta f_G \right] \right].$$

(C20)

To get the last line in (C20), we have used the fact that equilibrium distributions are isotropic. It is interesting to notice that (C20) can be also written as

$$\Pi_{NS} = \frac{1}{3} \int \frac{dwd^2pT}{v} \left[ \left( \frac{w^2}{\tau^2} + p^2_T + m^2 - m^2 \right) \left[ kQ(\delta f_{Q+} + \delta f_{Q-}) + kG\delta f_G \right] \right]$$

$$= -\frac{m^2}{3} \int \frac{dwd^2pT}{v} \left[ kQ(\delta f_{Q+} + \delta f_{Q-}) \right],$$

(C21)

where we used the Landau matching condition (C4) and the fact that gluons are massless.

Using the notation introduced above we find

$$\Pi_{NS} = -\frac{\tau_{eq}}{3} \int \frac{dwd^2pT}{v} \left( \frac{w^2}{\tau^2} + p^2_T \right) \left[ f_{3S} \left( \frac{w^2}{v^2\tau^2T} + \frac{v}{\tau^2T} \ln \frac{T}{\mu} \right) \right]$$

$$- \frac{\tau_{eq}}{3} \int \frac{dwd^2pT}{v} \left( \frac{w^2}{\tau^2} + p^2_T \right) f_{2D} \frac{d}{dT} \left( \frac{\mu}{T} \right)$$

$$- \frac{\tau_{eq}}{3} \int \frac{dwd^2pT}{v} \left( \frac{w^2}{\tau^2} + p^2_T \right) \left[ f_{3S} \left( \frac{w^2}{v^2\tau^2T} - \frac{v}{\tau^2T} \kappa_1 \right) \right]$$

$$+ \frac{\tau_{eq}}{3\tau T} \int \frac{dwd^2pT}{v} \left( \frac{w^2}{\tau^2} + p^2_T \right) f_{2D} \kappa_2.$$  

(C22)

Due to boost-invariance, the integral above can be done in the plane $z = 0$, where $w = p_LT$, $v = E_p t$. Since $f_{3S}$ and $f_{2D}$ are isotropic, we obtain

$$\Pi_{NS} = -\frac{\tau_{eq}}{3\tau T} \int d^3p p^2 \left[ f_{3S} \left( \frac{p^2}{3E_p^2} - \kappa_1 \right) \right] + \frac{\tau_{eq}}{3\tau T} \int \frac{d^3p}{E_p} p^2 f_{2D} \kappa_2.$$  

(C23)

For the Bjorken flow we have $\partial_\mu U^\mu = 1/\tau$, thus the Navier–Stokes relation $\Pi_{NS} = -\zeta \partial_\mu U^\mu$ allows us to identify the bulk pressure as

$$\zeta = \frac{\tau_{eq}}{3T} \int d^3p p^2 \left[ f_{3S} \left( \frac{p^2}{3E_p^2} - \kappa_1 \right) \right] - \frac{\tau_{eq}}{3T} \int \frac{d^3p}{E_p} p^2 f_{2D} \kappa_2.$$  

(C24)

Similarly, starting from (C21) we find

$$\zeta = \frac{\tau_{eq}m^2}{3T} \int d^3p \left[ f_{2S} \left( \kappa_1 - \frac{p^2}{3E_p^2} \right) \right] + \frac{\tau_{eq}m^2}{3T} \int \frac{d^3p}{E_p} f_{2D} \kappa_2,$$  

(C25)

which leads to (90).
