Abstract. The widespread use of both heavy metals and antibiotics in livestock farming, followed by their subsequent arrival on agricultural soils through manure and slurry spreading, has become a problem of vital importance for human health and the environment. In the current research, a laboratory experiment was carried out for 42 d to study tolerance and co-tolerance of three tetracycline antibiotics (tetracycline, TC; oxytetracycline, OTC; chlortetracycline, CTC) in soils polluted with heavy metals (As, Cd, Zn, Cu, Ni, Cr, and Pb) at high concentrations (1000 mg kg⁻¹ of each one, separately). Pollution induced community tolerance (PICT) of the bacterial community was estimated using the leucine incorporation technique. The log IC₅₀ (logarithm of the concentration causing 50% inhibition in bacterial community growth) values obtained in uncontaminated soil samples for all the heavy metals tested showed the following toxicity sequence: Cu > As > Cr ≥ Pb > Cd > Zn > Ni. However, in polluted soil samples the toxicity sequence was Cu > Pb ≥ As ≥ Cr ≥ Ni ≥ Zn. Moreover, at high heavy metal concentrations, the bacterial communities showed tolerance to the metal itself, this taking place in the long term for all the metals tested. The bacterial communities of the soil polluted with heavy metals showed also long-term co-tolerance to TC, OTC, and CTC. This kind of study, focusing on the eventual increases of tolerance and co-tolerance of bacterial communities in agricultural soil, favored by the presence of different kinds of pollutants, is of crucial importance, mostly bearing in mind that the appearance of antibiotic resistance genes in soil bacteria could be transmitted to human pathogens.

1 Introduction

The accumulation of heavy metals in soils is a widespread problem all over the world. Some anthropogenic activities, such as mining, industrial production, agriculture, or livestock farming, are among the main sources of release of heavy metals to the terrestrial environment (Abdu et al., 2017). The use of heavy metals in livestock production is a common practice, since commercial feeds are enriched with essential elements (such as Cu and Zn) to prevent diseases and obtain an optimal growth rate (Sager, 2007; Wu et al., 2013). In fact, the presence of high heavy metal concentrations in swine manure has been reported by Hölzel et al. (2012), specifically for Zn (up to 8239 mg kg⁻¹) and for Cu (up to 3387 mg kg⁻¹). In addition, Wang et al. (2013) found up to 1602 mg kg⁻¹ for Cr in layer manure, while Zhang et al. (2012) detected up to 300 mg kg⁻¹ for Pb and...
up to 100 mg kg\(^{-1}\) for Ni in poultry manure. Finally, Liu et al. (2020) reported up to 60 mg kg\(^{-1}\) for Cd and up to 89 mg kg\(^{-1}\) for As in pig manure. In view of that, these and other heavy metals are considered a serious problem for public health, especially because these toxic elements tend to accumulate in soils, where they may reach high and progressively increasing concentrations (Kabata-Pendias, 2000; Huang et al., 2007). Moreover, veterinary antibiotics are also widely used for the treatment of bacterial infections (Boxall et al., 2003), and their consumption has been increasing in recent decades, with the estimate of world use for 2030 being 105.596 t (Van Boeckel et al., 2015). The antibiotics most widely used in veterinary medicine in the European Union are tetracyclines (TCs), and specifically tetracycline (TC), oxytetracycline (OTC), and chlortetracycline (CTC) (European Medicines Agency, 2016). Both heavy metals and antibiotics for veterinary use are poorly absorbed by the intestines of animals, causing a high percentage of them to be excreted in feces and urine (Kormegay et al., 1976; Sarmah et al., 2006). In this sense, it has been reported that tetracycline antibiotic concentrations in manure may reach values as high as 746 mg kg\(^{-1}\) for CTC (Pan et al., 2011), 211 mg kg\(^{-1}\) for OTC, and 300 mg kg\(^{-1}\) for TC (Widyasari-Mehta et al., 2016). The presence of high levels of heavy metals and veterinary antibiotics in farmland soils is due to the repeated applications of manure and slurries (as well as sewage sludge) as organic fertilizers (Hamscher et al., 2002; Nicholson et al., 2003). Once in the soil, these compounds can interact with soil microbial communities and modify their structure and function (Hattori, 1992; Thiele-Brühn and Beck, 2005; Chien et al., 2008; Giller et al., 2009; Caban et al., 2018).

The increase of the concentration of any pollutant in soils may suppose a selection pressure for soil bacterial communities, causing tolerance to that pollutant (Blanch, 2002). This effect may be useful to quantify the harmful repercussions produced by pollutants on soil bacteria and is called pollution-induced community tolerance (PICT). Agricultural soils, highly influenced by anthropogenic activities, deserve special attention since they are recognized as the largest reservoirs of antibiotic-resistant genes, receiving antibiotics from veterinary use (through repeated applications of manure and slurries, as indicated above), as well as heavy metals (Ji et al., 2012). Therefore, the resistance of soil bacterial communities to antibiotics has become a crucial threat at a world scale, and the study of whether bacterial communities generate co-tolerance to antibiotics in the presence of heavy metals (as well as of how and to which degree it is developed) is of vital importance.

Several previous studies have focused on co-tolerance among different heavy metals and antibiotics (Berg et al., 2010; Sarma et al., 2010; Fernández-Calviño and Bååth, 2013; Song et al., 2017; Santás-Miguel et al., 2020a; Zhong et al., 2021). Specifically, Fernández-Calviño and Bååth (2013) evaluated the tolerance of soil bacterial community to three antibiotics (vancomycin, tetracycline, and tylosin) in one soil polluted with different Cu concentrations (2–32 mmol Cu kg\(^{-1}\)) and observed an increase in the co-tolerance of soil bacterial communities to tetracycline (at \(\geq 8\) mmol Cu kg\(^{-1}\)), tylosin (at \(\geq 16\) mmol Cu kg\(^{-1}\)), and vancomycin (at \(\geq 16\) mmol Cu kg\(^{-1}\)). Song et al. (2017) assessed the effects of adding different Cu and Zn concentrations (33–1000 and 165–5000 mg kg\(^{-1}\), respectively) on the tolerance of soil bacterial communities to tetracycline, finding that the co-tolerance to the antibiotic significantly increased in soils where Cu concentrations were \(\geq 365\) mg kg\(^{-1}\), and Zn concentration was \(\geq 264\) mg kg\(^{-1}\).

Zhong et al. (2021) studied the tolerance to tetracycline and vancomycin in 10 mine soil samples with the presence of Cu (361–4399 mg kg\(^{-1}\)), Zn (33–3811 mg kg\(^{-1}\)), and Pb (195–20 239 mg kg\(^{-1}\)). These authors found that, in general, there were increases in tolerance of soil bacterial communities to antibiotics, although they did not detect a systematic pattern in the co-tolerance to tetracycline associated with heavy metal concentrations, whereas the induced levels of heavy metal tolerance coincided with elevated levels of tolerance to vancomycin. However, until now, there have been no studies evaluating the effect of a wide range of different heavy metals present in livestock manure on the tolerance shown by soil bacterial communities against each of the three tetracycline antibiotics most used in animal husbandry. Therefore, the objective of this study is to determine the eventual development of tolerance in soil bacterial communities to heavy metals in agricultural soils contaminated individually with 1000 mg kg\(^{-1}\) of As, Cd, Zn, Cu, Ni, Cr, and Pb and also the eventual generation of co-tolerance to the antibiotics tetracycline, oxytetracycline, and chlortetracycline, using the leucine incorporation technique as the endpoint. Previous works using Cu and/or Zn showed that the heavy metal concentrations needed to induce bacterial community tolerance to antibiotics in soils are high, generally \(\geq 1000\) mg kg\(^{-1}\) (Fernández-Calviño and Bååth, 2013; Song et al., 2017). Although these values are not very frequent, they could accumulate after enough time has elapsed, since heavy metals are not degraded in soils. In this regard, Mirlean et al. (2007) found Cu concentrations higher than 1000 mg kg\(^{-1}\) in Brazilian vineyard soils. Therefore, the results of the current research could be relevant in order to define appropriate management practices for waste and fertilizers in agricultural soils.

2 Material and methods

2.1 Chemicals

Tetracycline hydrochloride (CAS 64-75-5; \(\geq 95\%\) in purity), oxytetracycline hydrochloride (CAS 2058-46-0; \(\geq 95\%\) in purity), and chlortetracycline hydrochloride (CAS 64-72-2; \(\geq 97\%\) in purity), all three supplied by Sigma-Aldrich (Steinheim, Germany), were used for soil spiking.
The heavy metals added to the soil samples for determining bacterial community tolerance were arsenic (as Na₂HAsO₄ 7H₂O, CAS; 10048-95-0), cadmium (as Cd(NO₃)₂ 4H₂O, CAS 10022-68-1), zinc (as Zn(NO₃)₂ 6H₂O, CAS; 10196-18-6), copper (as Cu(NO₃)₂ 2.5H₂O, CAS 19004-19-4), nickel (as Ni(NO₃)₂ 6H₂O, CAS 13478-00-7), chromium (as K₂Cr₂O₇, CAS 7778-60-9), and lead (as Pb(NO₃)₂, CAS 10099-74-8), all of them supplied by Panreac (Barcelona, Spain).

2.2 Soil samples

An agricultural soil from Sarria (NW of Spain) was selected from a set of soils previously analyzed by Conde-Cid et al. (2018). Total concentrations of Na, K, Ca, Mg, Al, Fe, and Mn, as well as of As, Cd, Cr, Cu, Ni, Pb, and Zn, were determined using inductively coupled plasma mass spectrometry (ICP-MS; 820-NS, Varian, Palo Alto, CA, USA), which was carried out after performing a microwave-assisted digestion using 65% nitric acid. As, Cd, Cr, Cu, Ni, Pb, and Zn bioavailability at 0 and 42 d of incubation was assessed performing extractions with 0.01 M CaCl₂ (Novozamsky et al., 1993) and with EDTA (ethylenediamine tetra-acetic acid) (Lakanen and Erviö, 1971). The electrical conductivity (EC) was analyzed using distilled water for extraction, with 1.5 as the soil:water ratio, and measuring in a conductivity meter. Moreover, this soil was previously used for measuring the bacterial growth on days 1 and 42 of incubation, following the protocol established by Bååth (1994) and Bååth et al. (2001). The bacterial community tolerance was determined according to Bååth (1992) and to Díaz-Raviña et al. (1994), with certain modifications indicated below and using the leucine incorporation method (Bååth, 1994; Bååth et al., 2001). Briefly, soil samples obtained from each microcosm were mixed with distilled water (rate 1: 20 (w/v)), using a multi-vortex shaker for 3 min at maximum intensity. Then, the soil/water mixture was centrifuged at 1000 × g for 10 min to obtain the soil bacterial suspension (supernatant). Aliquots of 1.5 mL of the supernatant were transferred to 2 mL centrifugation tubes, in which 150 μL of pollutant solution (containing heavy metals or antibiotics) was subsequently added. As a result, a total of seven heavy metals (As, Cd, Zn, Cu, Ni, Cr, and Pb) and three antibiotics (TC, OTC, and CTC) were added to the bacterial suspensions (thus, a total of 10 pollutants were studied), and these plus a control (only water added) were used for each sample. The final concentrations of heavy metals added ranged between 10⁻² and 10⁻⁶ mol L⁻¹, while the range for antibiotics went from 400 to 6 × 10⁻³ mg L⁻¹. The bacterial community growth was estimated after a pre-incubation step of 24 h.
where bacterial suspensions were added with the different concentrations of antibiotics before the leucine incorporation assay (Berg et al., 2010; Fernández-Calviño and Bååth, 2013). The \(^{3}H\) leucine incorporation was then measured on each micro-centrifugation tube, as follows: a volume of 0.2 µL \(^{3}H\) leucine (3.7 MBq mL\(^{-1}\) and 0.574 TBq mmol\(^{-1}\); Amersham) was added with non-labeled leucine to each tube, resulting in 275 nM leucine in the bacterial suspensions. After 3 h of incubation, the bacterial growth was terminated by adding 75 mL of 100 % trichloroacetic acid. Washing was performed as described by Bååth et al. (2001), and a subsequent measurement of radioactivity was carried out using a liquid scintillation counter (Tri-Carb 2810 TR, PerkinElmer, USA).

2.4 Data analyses

The tolerance of the bacterial community to the seven heavy metals (As, Cd, Zn, Cu, Ni, Cr, and Pb) and the three tetracycline antibiotics (TC, OTC, and CTC) was estimated as log IC\(_{50}\), the logarithm of the concentration that resulted in 50 % inhibition of bacterial community growth. The log IC\(_{50}\) was calculated using a logistic model, as follows:

\[
\text{log IC}_{50} = \frac{c}{[1 + e^{b(X-a)}]},
\]

where \(Y\) is the measured level of leucine incorporation, \(X\) is the log of the contaminant substance (heavy metals (As, Cd, Zn, Cu, Ni, Cr, or Pb) or antibiotics (TC, OTC, or CTC)) added to the bacterial suspension, \(a\) is the log IC\(_{50}\), \(c\) is the bacterial growth rate in absence of the toxic substance, and \(b\) is a slope parameter indicating the inhibition rate. A higher value of log IC\(_{50}\) indicates a higher community tolerance, while a lower value indicates that the pollutants (heavy metals or antibiotics) are more toxic to the bacterial community.

3 Results and discussion

3.1 Toxicity of heavy metals on soil bacteria

The toxicity of the heavy metals on soil bacterial communities was tested in the agricultural soil in the short and long term (1 and 42 d of incubation). The bacterial growth results obtained for the soil samples polluted with 1000 mg kg\(^{-1}\) of As, Cd, Zn, Cu, Ni, Cr, or Pb (separately) and for the unpolluted soil (0 mg kg\(^{-1}\)) allowed us to establish a toxicity index for these heavy metals (Table 1). On day 1, the toxicity sequence was the following: \(\text{Cr} \geq \text{Cu} \geq \text{Ni} > \text{Cd} \geq \text{Zn} > \text{As} \geq \text{Pb}\). After 42 d of incubation the sequence was similar, with changes mainly affecting Ni and Cd: \(\text{Cr} > \text{Cu} > \text{Cd} > \text{Ni} \geq \text{Zn} > \text{As} > \text{Pb}\).

The data obtained in this study differ from those reported by other authors, which was expected, since the toxicity of heavy metals in soil microorganisms depends on the physicochemical characteristics of the soils (such as pH and carbon content), the concentrations of heavy metals added, and the incubation period (Hattori, 1992; Diaz-Raviña and Bååth, 1996; Nannipieri et al., 1997; Ahmad et al., 2005). Hattori (1992) evaluated the influence of Cd, Cr, Cu, Ni, Pb, and Zn on the microorganisms present in two soils after 4 weeks and obtained the toxicity sequence \(\text{Cd} > \text{Cu} > \text{Ni} > \text{Cr} > \text{Zn}\) for one of them (a Gleysol, with pH = 5.8 % and C = 0.5 %) and the sequence \(\text{Cu} > \text{Cd} > \text{Ni} > \text{Cr} > \text{Zn}\) for the other soil (an Andosol, with pH = 6.4 % and C = 3.2 %). Ahmad et al. (2005) measured the response of the microbial populations of one soil (pH = 7.6 % and C = 0.4 %) to Cu, Cd, Cr, Hg, Mn, Ni, Pb, and Zn at five incubation times, finding that the sensitivity of the bacterial populations depended on the functional group to which they belonged, the aerobic-heterotrophic bacteria being more sensitive to Ni, Pb, and Cu, while nitrogen-fixing bacteria were more sensitive to Cd and Pb. Bååth (1989) observed that the relative toxicity of metals decreased in the order Cd > Cu > Zn > Pb, although some differences were found among different investigations. Analyzing data obtained in different studies, it can be observed that, in general, the heavy metals that exert a higher effect on soil microorganisms are Cd and Cu. These results agree with those obtained using other organisms as endpoints, such as \textit{Daphnia magna}, \textit{Vibrio fischeri}, \textit{Lemna minor}, and \textit{Eisenia fetida}, which show that there is great variability in the toxicities caused by heavy metals but also that Cd and Cu are the most toxic (Neuhauser et al., 1985; Arambašić et al., 1995; Huynh and Bulich, 1995; Dirilgen, 2001; Hsieh et al., 2004; Teodorovic et al., 2009).

Table 1. Toxicity index values ± error of soil samples containing 0 mg kg\(^{-1}\) (control soil) and 1000 mg kg\(^{-1}\) of As, Cd, Zn, Cu, Ni, Cr, or Pb (individually), after 1 and 42 d of incubation.

| Heavy metal | 
|-------------|
| Day 1 | Day 42 |
| As | 0.69 ± 0.04 | 2.39 ± 0.18 |
| Cd | 0.12 ± 0.01 | 0.15 ± 0.00 |
| Zn | 0.15 ± 0.04 | 2.36 ± 0.04 |
| Cu | 0.03 ± 0.01 | 0.06 ± 0.01 |
| Ni | 0.05 ± 0.02 | 2.18 ± 0.39 |
| Cr | 0.01 ± 0.01 | 0.01 ± 0.00 |
| Pb | 0.72 ± 0.04 | 2.76 ± 0.06 |

3.2 Soil bacterial communities’ tolerance to heavy metals in the long term

Figure 1 shows the dose–response curves obtained for each heavy metal after 42 d of incubation, including data for each microcosm. These dose–response curves are sigmoidal, such as those reported by other authors (Díaz-Raviña et al., 1994; Cruz-Paredes et al., 2017; Song et al., 2017; Santás-Miguel et al., 2020a). The inhibition curves show the absence of bac-
terial growth inhibition at low heavy metals’ concentrations, but inhibition takes place at high doses, and it increased with dose. As a general trend, it is observed that the inhibition curves obtained for all heavy metals tested shift to the right with respect to the control (unpolluted soil). This shift to the right in the dose–response curves suggests the existence of soil bacterial community tolerance to the high heavy metals’ concentrations added to the soil used in this research (1000 mg kg$^{-1}$).

In this study, the dose–response curves fitted well to the logistic model, with $R^2$ ranging between 0.966 and 0.991 (mean $R^2 = 0.983$) for the control sample (0 mg kg$^{-1}$) and $R^2$ between 0.861 and 0.987 (mean $R^2 = 0.950$) for samples polluted with heavy metals (1000 mg kg$^{-1}$ of each one, individually).

Table 2 shows the log IC$_{50}$ values obtained from each dose–response curve. The unpolluted soil showed the lowest log IC$_{50}$ value for Cu ($-4.17 \pm 0.05$) and the highest value for Ni ($2.56 \pm 0.08$); i.e., the bacteria found in the bacterial suspension of unpolluted soils show high toxicity effects due to Cu and lower toxicity due to Ni. As regards the log IC$_{50}$ values obtained for the whole set of heavy metals tested, the following toxicity sequence was observed for the control (unpolluted soil): Cu $>$ As $>$ Cr $>$ Pb $>$ Cd $>$ Zn $>$ Ni. This toxicity sequence is similar to that reported by Díaz-Raviña et al. (1994), who studied the bacterial community tolerance to Cu, Cd, Zn, Ni, and Pb using the thymidine incorporation technique and found that Cu was the most toxic, while Ni showed the lowest toxicity on bacterial communities. However, the order of the rest of heavy metals differed from that observed in the current study, with the sequence being Cu $>$ Cd $>$ Zn $>$ Pb $>$ Ni.

Regarding the samples polluted with 1000 mg kg$^{-1}$ of each of the heavy metals separately, the lowest log IC$_{50}$ score corresponds to Cu ($-2.61 \pm 0.12$) and the highest to Zn ($-1.63 \pm 0.09$) (Table 2); i.e., the bacterial communities present in these microcosms are more sensitive to Cu than to Zn. The toxicity sequence, as a function of the log IC$_{50}$ values, was Cu $>$ Pb $>$ As $>$ Cd $>$ Cr $>$ Ni $>$ Zn.

The log IC$_{50}$ values obtained for each soil sample polluted with the highest heavy metal concentrations increased with respect to the control (unpolluted soil), indicating that the bacteria exposed to high levels of heavy metals developed tolerance to these pollutants. The highest increases in log IC$_{50}$ ($\Delta$log IC$_{50}$, Table 2) corresponded to Cr and Cu (1.58 and 1.56 units, respectively), followed by As, Zn, Cd, and Pb (1.35, 1.26, 1.16 and 1.08 units, respectively), whereas the increase was of 0.74 units for Ni. It is noted that the presence of high amounts of heavy metals in the soil causes bacterial communities to increase their tolerance to these pollutants (Díaz-Raviña et al., 1994; Díaz-Raviña and Bååth, 1996, 2001; Fernández-Calviño and Bååth, 2013; Santás-Miguel et al., 2020a; Zhong et al., 2021), although the magnitude of these increases seems to depend on the toxicity or initial pressure exerted by the metal on the soil bacterial communities.

Figure S2 (Supplement) shows the relation between the increase in tolerance to heavy metals and the toxicity exerted by each metal on the bacterial growth in the short term (1 d) and in the long term (42 d). It can be observed that the higher the bacterial growth inhibition on days 1 and 42 is, the greater the increase in tolerance is generated by bacterial communities to heavy metals. This behavior was observed for all the heavy metals studied except Ni. In fact, eliminating Ni, the relation becomes significant at day 1 ($r = 0.789$, $P < 0.05$) and at day 42 ($r = 0.730$; $P < 0.05$). The toxicity on soil bacterial communities due to heavy metals is related to their bioavailability in the soil environment. The time-course evolution of heavy metals’ bioavailability is shown in Table S2 (Supplement), indicating that in general they are highly bioavailable in the short term (with Ni showing the lowest bioavailability), while in the long term (concentrations in EDTA) their bioavailability decreases in a percentage of between 20% and 70% (although being less in the case of Ni, which remains constant over time).

The results suggest that the increase in soil bacterial community tolerance after the addition of heavy metals can be attributed to the immediate effect caused by the decay of sensitive species and to a posterior effect caused by different competitive capacities and ulterior adaptation in the bacteria remaining. This effect of heavy metals in soil has been observed previously by Diaz-Raviña and Bååth (1996) for Zn, Cd, Ni, Cu, and Pb and by Fernández-Calviño and Bååth (2016) for Cu.

### 3.3 Soil bacterial communities’ tolerance to tetracycline antibiotics in the long term

Figures 2, 3, and 4 show dose–response curves obtained at 42 d of incubation for each heavy metal added to the soil at 1000 mg kg$^{-1}$, after the exposure of bacterial suspension from each microcosm to concentrations of tetracyclines antibiotics (TC, OTC, and CTC) ranging from 400 to $6 \times 10^{-3}$ mg L$^{-1}$. The inhibition curves obtained for these tetracycline antibiotics are sigmoidal. As a general trend, the dose–response curves are shifted to the right with respect to the control, and in some cases the tetracycline antibiotics did not show an inhibitory effect on bacterial communities.

These dose–response curves fitted well to the logistic model, with $R^2$ ranging between 0.925 and 0.982 (mean $R^2 = 0.956$) for TC samples, between 0.771 and 0.997 (mean $R^2 = 0.952$) for OTC samples, and from 0.959 to 0.992 (mean $R^2 = 0.976$) for CTC samples.

Table 3 shows the log IC$_{50}$ values obtained from each dose–response curve, being $1.83 \pm 0.06$ for the control sample after exposure of the bacterial suspension to different concentrations of TC. In general, the log IC$_{50}$ values obtained for each microcosm polluted with 1000 mg kg$^{-1}$ of each heavy metal and subsequently exposed to TC increased
with respect to the control. The magnitude of these increases varies as a function of the heavy metal, being 0.40, 0.45, and 0.43 units for Pb, Zn, and As and 0.50 units to Ni. However, the bacterial communities of soils contaminated with Cd, Cu, and Cr do not show inhibition in their growth when exposed to TC, and, therefore, their log IC$_{50}$ cannot be determined due to the high community tolerance to TC. Consequently, heavy metals that do not show inhibition have been assigned a log IC$_{50}$ value of $>2.60$, since it is the maximum concentration tested in the current study. The log IC$_{50}$ value obtained for the control soil in presence of OTC was $1.11 \pm 0.08$. Regarding the log IC$_{50}$ values obtained for the samples polluted with heavy metals, it can be observed that, after the exposure of the bacterial suspension to OTC, there was an increase in these values with respect to the control, going from 0.23 to 0.57 for Pb, Cd, Zn, As, and Ni and being 1.56 for Cu. Regarding Cr, the exposure of the soil bacterial suspension to OTC did not cause inhibition of its growth, and, therefore, as in the case of Cd, Cu, and Cr for TC, the value of $>2.60$ (maximum concentration tested) was assigned.

Finally, the log IC$_{50}$ value obtained for the control soil added with CTC was $1.52 \pm 0.10$. After exposure of the bacterial suspensions to CTC, the log IC$_{50}$ values obtained for the samples polluted with heavy metals showed an increase with respect to the control, going from 1.75 to 2.19 for all the heavy metals except for Cr, which did not show inhibition of bacterial growth when exposed to different concentrations of CTC. Therefore, it can be indicated that bacterial communities exposed to high concentrations of heavy metals show great co-tolerance to CTC. In general, the increase in tolerance obtained for TC, OTC, and CTC cannot be related to the toxicity of heavy metals in the soil, at 1 and 42 d of incubation (data not shown).
Figure 2. Dose–response curves obtained after the addition of 10 different concentrations of tetracycline (TC) to bacterial suspension extracted from soil samples polluted with 1000 mg kg\(^{-1}\) of As (a), Cd (b), Zn (c), Cu (d), Ni (e), Cr (f), or Pb (g), each of them added separately, after 42 d of incubation. Black lines represent the dose–response curves obtained for the unpolluted soil (control), and dashed orange lines are dose–response curves for soils polluted with 1000 mg kg\(^{-1}\) of one of the heavy metals. Average values \((n = 3)\) with coefficients of variation always < 5%.

Table 2. Estimated values of log IC\(_{50}\) ± error and \(R^2\) from fits to a logistic model of soil samples containing 0 mg kg\(^{-1}\) (control soil) and 1000 mg kg\(^{-1}\) of As, Cd, Zn, Cu, Ni, Cr, or Pb (individually). The increases in tolerance \((\Delta\log IC_{50} = \log IC_{50} \text{ polluted} – \log IC_{50} \text{ control})\) were calculated for each heavy metal.

| Heavy metal | Control soil log IC\(_{50}\) ± error | Control soil \(R^2\) | Heavy-metal-polluted soil log IC\(_{50}\) ± error | Heavy-metal-polluted soil \(R^2\) | \(\Delta\log IC_{50}\) |
|-------------|----------------------------------|-----------------|----------------------------------|-----------------|-----------------|
| As          | \(-3.63 \pm 0.11\)               | 0.970           | \(-2.28 \pm 0.04\)               | 0.987           | 1.35            |
| Cd          | \(-3.37 \pm 0.07\)               | 0.988           | \(-2.21 \pm 0.06\)               | 0.966           | 1.16            |
| Zn          | \(-2.89 \pm 0.06\)               | 0.988           | \(-1.63 \pm 0.09\)               | 0.966           | 1.26            |

* The value of 2.6 is the maximum value tested.

Figure 3. Dose–response curves obtained after the addition of 10 different concentration of oxytetracycline (OTC) to bacterial suspension extracted from soil samples polluted with 1000 mg kg$^{-1}$ of As (a), Cd (b), Zn (c), Cu (d), Ni (e), Cr (f), or Pb (g), each of them added separately, after 42 d of incubation. Black lines represent the dose–response curves obtained for the unpolluted soil (control), and dashed blue lines are dose–response curves for soils polluted with 1000 mg kg$^{-1}$ of one of the heavy metals. Average values ($n = 3$) with coefficients of variation always < 5%.
Co-tolerance to TC generated by soil bacterial communities exposed to heavy metals has been previously demonstrated (Berg et al., 2010; Fernández-Calviño and Bååth, 2013; Song et al., 2017). Song et al. (2017) observed the existence of co-tolerance to TC in a microcosm exposed to concentrations of Cu ≥ 333 and Zn ≥ 500 mg kg\(^{-1}\). Fernández-Calviño and Bååth (2013) found co-tolerance to TC of soil bacterial communities in contaminated soils with concentrations of Cu ≥ 500 mg kg\(^{-1}\). The results shown in these studies agree with what was observed in the present work, indicating that soil bacterial communities exposed to high concentrations of heavy metals (1000 mg kg\(^{-1}\)) generate co-tolerance to tetracycline. However, Zhong et al. (2021) did not observe co-tolerance to TC in soils contaminated with Cu, Zn, and Pb, while they found co-tolerance of soil bacterial communities to vancomycin.

This co-tolerance of soil bacterial communities to TC at high concentrations of heavy metals is also observed for OTC and CTC. The results obtained in this study agree with the data reported in studies previously carried out by Santás-Miguel et al. (2020a), where co-tolerance of soil bacterial communities to tetracycline antibiotics (TC, OTC, and CTC) was observed in soils with concentrations of Cu ≥ 1000 mg kg\(^{-1}\) after 42 d of incubation.

It is relevant that co-tolerance studies, in general, focus on a reduced number of heavy metals (generally Cu) and tetracycline antibiotics, while for the first time the present work shows the effect of seven different heavy metals as regards the co-tolerance to the three most used tetracycline antibiotics (TC, OTC, and CTC). It is also remarkable that the role of heavy metals as a co-selection factor to generate antibiotic resistance genes has been studied for a wide variety of heavy metals and antibiotics (Berg et al., 2010; Dickinson et al., 2019; Cao et al., 2020; Mazhar et al., 2021), and, although in the present study antibiotic resistance genes (ARGs) have not...
been studied directly, the resistance of soil bacterial communities to heavy metals and tetracycline antibiotics (TC, OTC, and CTC) could be detected using the leucine incorporation method. The heavy metal levels of the tested microcosms (1000 mg kg\(^{-1}\)) are really very high, but they should not be considered unrealistic, since heavy metals are not easily biodegradable, and therefore their concentrations can increase over time (Li et al., 2015), reaching very high levels in the soil (Smolders et al., 2004; Spiteri et al., 2005; Zhuang et al., 2009; Komárek et al., 2010). Therefore, soils contaminated with high concentrations of heavy metals could become hotspots of ARGs, which would pose a potential danger to public health, since they could be transmitted to humans (Forsberg et al., 2012).

4 Conclusions

In the current study it was evidenced that heavy metals present in soils show wide variability as regards the toxicity they exert on bacterial communities, with Cd and Cu being the most toxic. Specifically, soil samples contaminated with a high concentration (1000 mg kg\(^{-1}\)) of each of seven different heavy metals (As, Cd, Zn, Cu, Ni, Cr, and Pb), added separately, showed tolerance of the soil bacterial communities to the heavy metals themselves, compared to the control soil. Besides, it was shown that the higher the effect of heavy metals in the short and long term, the greater the increase in tolerance to metals generated in the soil bacterial communities (except for Ni). In addition, soil samples contaminated with high concentrations of heavy metals also showed co-tolerance of soil bacterial communities to tetracycline, oxytetracycline, and chlortetracycline for all the metals tested, compared to the control soil. However, in general, there was no correlation between the initial damage exerted by heavy metals in the short and long term and the co-tolerance shown by soil bacterial communities to tetracycline antibiotics. Future studies could give further details about the potential interactions of different pollutants present in agricultural soils, which can be considered relevant as regards environmental preservation and public health.
