PROFINITE COMPLETION OF OPERADS AND THE
GROTHENDIECK-TEICHMÜLLER GROUP

GEOFFROY HOREL

Abstract. In this paper, we prove that the group of homotopy automorphisms of the profinite completion of the operad of little 2-disks is isomorphic to the profinite Grothendieck-Teichmüller group. In particular, the absolute Galois group of $\mathbb{Q}$ acts faithfully on the profinite completion of $\mathcal{E}_2$ in the homotopy category of profinite weak operads.

Introduction

The main result of this paper can be slightly imprecisely stated as follows:

Theorem (7.4). The group of homotopy automorphisms of the profinite completion of the operad $\mathcal{E}_2$ of little 2-disks is isomorphic to the Grothendieck-Teichmüller group.

We now introduce the main characters of this story.

Key words and phrases. little disk operad, profinite completion, Grothendieck Teichmüller group.

The author was supported by Michael Weiss's Humboldt professor grant.
**Profinite completion.** Profinite completion of spaces has been introduced by Artin and Mazur in [AM69]. It is a homotopical analogue of the notion of profinite completion of groups. A space is said to be \(\pi\)-finite if it has finitely many path components and if for any choice of base point, its homotopy groups based at that point are finite and almost all zero. For a general space \(X\) the category of \(\pi\)-finite spaces with a map from \(X\) fails to have an initial object in general. Nevertheless, there is an object in the pro-category of \(\text{Ho}\)\(S\) which plays the role of this missing universal \(\pi\)-finite space. This object is the definition of the profinite completion of \(X\) according to Artin and Mazur.

For our purposes this construction of Artin and Mazur is not sufficient because it gives a pro-object in the homotopy category of spaces and we need a point-set level lift of this construction. More precisely, we need a category \(\hat{S}\) of profinite spaces ideally equipped with a model structure and a profinite completion functor \((\_): S \to \hat{S}\) ideally a left Quillen functor. We would also like a comparison map \(\text{Ho}\hat{S} \to \text{Pro(Ho}S)\) which maps \(\hat{X}\) to an object that is isomorphic to the Artin-Mazur profinite completion. A model structure fulfilling all these requirements has been constructed by Gereon Quick in [Qui08]. There could however be several distinct profinite completion functors lifting Artin and Mazur’s construction. The language of \(\infty\)-categories gives us a way to formulate precisely what profinite completion should be. In [BIH15], Barnea, Harpaz and I prove that Quick’s construction is “correct” in the sense that its underlying \(\infty\)-category is the \(\infty\)-category obtained by freely adjoining cofiltered limits to the \(\infty\)-category of \(\pi\)-finite spaces.

The little disk operad. The little 2-disk operad is an operad in topological spaces. It was introduced by May and Boardman-Vogt in order to describe the structure existing on the 2-fold loops on a simply connected based space that allows one to recover that space up to weak equivalence (see [May72] for details about this theorem). The \(n\)-th space of the operad of little two disks has the homotopy type of the space of configurations of \(n\) points in \(\mathbb{R}^2\). The latter space is well-known to be equivalent to the classifying space of the pure braid group on \(n\) strands. This fact allows for the existence of groupoid models of \(E_2\) i.e. of operads in groupoids which give a model of \(E_2\) when applying levelwise the classifying space functor. One of these models called \(\mathcal{P}a\mathcal{B}\), the operad of parenthesized braids is particularly nice. First of all, it is very well-behaved homotopically as an operad in groupoids (see 5.7 for a precise statement). Moreover, it is a very fundamental object in category theory as it is the operad describing the structure of a braided monoidal category.

The Grothendieck-Teichmüller group. The Grothendieck-Teichmüller group was introduced by Drinfel’d and Ihara following an idea of Grothendieck. Its story originates in Belyi’s theorem. One was to find a finite presentation of \(\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})\) whose \(n\)-th level is equivalent as a profinite groupoid to the profinite completion of \(K_n\). One can rephrase Drinfel’d’s definition by saying that the Grothendieck-Teichmüller group is the group of automorphisms of \(\mathcal{P}a\mathcal{B}\) that induce the identity on objects.
PROFINITE COMPLETION OF OPERADS

Content of the present paper. Using Drinfel’d’s definition of $\hat{\mathcal{G}}T$, our proof relies on the observation that $\hat{\mathcal{P}}aB$ is a groupoid model for the profinite completion of $E_2$ and that the action of $\hat{\mathcal{G}}T$ on $\hat{\mathcal{P}}aB$ induces an isomorphism from $\hat{\mathcal{G}}T$ to the group of homotopy automorphisms of $\hat{\mathcal{P}}aB$. A technicality that we have to deal with is that the profinite completion functor from spaces to profinite spaces does not preserve products. Thus, applying profinite completion to each level of an operad does not yield an operad in general. To solve this problem we use the formalism of algebraic theories and their homotopy algebras initiated by Badzioch in [Bad02]. This allows us to relax the axiom of operads and work with what we call weak operads. In the appendix, we define the notion of weak operads in a reasonable model category and encode their homotopy theory by a model structure. We can then define the profinite completion functor as a functor from weak operads in spaces to weak operads in profinite spaces.

In this paper, we also study the automorphisms of the topological operad $E_2$ before completion. There is a well-known action of the orthogonal group $O(2, \mathbb{R})$ on $E_2$ and we prove in theorem 7.5 that the induced map from $O(2, \mathbb{R})$ to $\text{Map}^h_{\text{Ops}}(E_2, E_2)$ is a weak equivalence. In particular, the group of connected components of $\text{Map}^h_{\text{Ops}}(E_2, E_2)$ is isomorphic to $\mathbb{Z}/2$.

Future work. It has been conjectured that the operad $E_2$ should have an algebro-geometric origin (see for instance the appendix of [Mor03]). More precisely, there should be an operad in a category of schemes (or a generalization thereof) over $\mathbb{Q}$ whose complex points form a model for $E_2$. Applying the étale homotopy type to this conjectural operad would yield an operad in profinite spaces with an action of $\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$. Our main result seems to be a compelling evidence for this fact and we hope to tackle this problem in future work.

Related work. We learned about this problem in a talk by Dwyer at the MSRI in 2014 (see [Dwy14, 56 min 40]). Our result should be compared to an analogous result due to Fresse (see [Fre15a] and [Fre15b]) which proves that the group of homotopy automorphisms of the rational completion of $E_2$ is isomorphic to the pro-unipotent Grothendieck-Teichmüller group. The work of Sullivan on the Adams conjecture (see [Sul74]) especially the observation that $\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ acts on the profinite completion of the spectrum $KU$ was a big influence on this work. The idea of using algebraic theories to relax the axiom of operads is an essential ingredient in this paper. This idea was initiated by Badzioch in [Bad02] and continued by Bergner in [Ber06] in the multi-sorted case. This work also relies a lot on good point set level models for profinite completion constructed by Morel [Mor96] and Quick [Qui08].

Acknowledgements

I wish to thank Benoit Fresse for generously sharing some of his insights and for noticing a mistake in an earlier version of this paper. I am grateful to Benjamin Collas for a brilliant talk about Fresse’s work in the Leray seminar in Münster that introduced me to this problem and for several helpful email exchanges about the Grothendieck-Teichmüller group. I also want to thank Ilan Barnea and Gereon Quick for helpful conversations and email exchanges.

Notations

- For a category $C$ we denote by $C(x, y)$ the set of morphisms from $x$ to $y$ in $C$. If the category is simplicially enriched, we denote by $\text{Map}_C(x, y)$ the mapping space from $x$ to $y$.
- We generically denote by $\emptyset$ (resp. $\ast$) the initial (resp. terminal) object of a category $C$. The category should be obvious from the context.
- For $C$ a model category, we denote by $\text{Ho}C$ the homotopy category. The derived mapping spaces in $C$ are denoted $\text{Map}^h_C(X, Y)$. They are only well-defined up to homotopy. They can be defined using Dwyer-Kan’s hammock localization or if $C$ is a simplicial model category by taking cofibrant-fibrant replacements of $X$ and $Y$. Note that $\text{Ho}C(x, y) \cong \pi_0\text{Map}^h_C(x, y)$. 

We denote an isomorphism by \( \cong \) and a weak equivalence by \( \simeq \).

We denote by \( \mathsf{S} \) the category of simplicial sets, and \( \mathsf{G} \) the category of groupoids. They are equipped respectively with the Kan-Quillen model structure and the canonical model structure.

For \( k \) a non-negative integer, we denote by \( \mathsf{I}[k] \) the groupoid completion of the category \([k]\).

We denote by \( \mathsf{S}^q \) the category of simplicial sets equipped with Quick’s model structure (see [Qui08]) and by \( \mathsf{G}^q \) the category of profinite groupoids equipped with the model structure of theorem 3.12.

For \( \mathcal{C} \) a category with products, we denote by \( \mathbf{OpC} \) the category of reduced or unitary operads in \( \mathcal{C} \). They are the operads which take the value \( \ast \) in arity 0. Since all operads in this work are unitary, we simply call them operads.

We denote by \( \mathbf{POpC} \) the category of preoperads in \( \mathcal{C} \) (i.e. the category of contravariant functors from \( \Psi \) to \( \mathcal{C} \)). If \( \mathcal{C} \) is a suitable model category, we denote by \( \mathbf{WOpC} \) the model category of weak operads in \( \mathcal{C} \) (see proposition A.11). The relevant definitions can be found in the appendix.

We denote the little 2-disks operad by \( \mathcal{E}_2 \). We implicitly see \( \mathcal{E}_2 \) as an operad in \( \mathsf{S} \) rather than topological spaces. We denote by \( \mathcal{E}_2^q \) the weak operad in spaces \( \mathsf{N}^q \mathcal{E}_2 \). We denote by \( \mathcal{P}_{\mathcal{A}\mathcal{B}} \) the operad of parenthesized braids (see construction 5.1).

**Sketch of the proof**

It is actually more convenient to prove a slightly more general result. There is a monoid \( \mathcal{G}T \) defined by Drinfel’d whose group of units is \( \mathcal{G}T \) and we in fact prove that the endomorphisms of the profinite completion of \( \mathcal{E}_2 \) in the category of weak operads in profinite spaces is isomorphic to \( \mathcal{G}T \).

The four important categories in this work are \( \mathsf{S}, \mathsf{S}^q, \mathsf{G} \) and \( \mathsf{G}^q \). They are respectively the category of simplicial sets, profinite spaces (i.e. simplicial objects in profinite sets), groupoids and profinite groupoids (i.e. the pro-category of the category of groupoids with finitely many morphisms). Each of them has a model structure. The model structure on \( \mathsf{S} \) and \( \mathsf{G} \) are respectively the Kan-Quillen and canonical model structure. The model structure on \( \mathsf{S}^q \) is constructed by Quick in [Qui08] and the model structure on \( \mathsf{G}^q \) is a groupoid analogue of Quick’s model structure constructed in section 3 of this paper. There is a classifying space functor \( \mathcal{B} \) from \( \mathsf{G} \) to \( \mathsf{S} \) and from \( \mathsf{G}^q \) to \( \mathsf{S}^q \). In both cases, \( \mathcal{B} \) is a right Quillen functor. There are also profinite completion functors \( (-) : \mathsf{G} \to \mathsf{G}^q \) and \( (-) : \mathsf{S} \to \mathsf{S}^q \) that are both left Quillen.

There is an operad \( \mathcal{P}_{\mathcal{A}\mathcal{B}} \) in the category of groupoids which is a groupoid model of \( \mathcal{E}_2 \) in the sense that \( B\mathcal{P}_{\mathcal{A}\mathcal{B}} \) is weakly equivalent to \( \mathcal{E}_2 \). The levelwise profinite completion of \( \mathcal{P}_{\mathcal{A}\mathcal{B}} \) is an operad \( \mathcal{P}_{\mathcal{A}\mathcal{B}} \) in profinite groupoids. The monoid \( \mathcal{G}T \) is defined by Drinfel’d to be the monoid of endomorphisms of \( \mathcal{P}_{\mathcal{A}\mathcal{B}} \) which induce the identity on objects.

There is a functorial path object in the category of profinite groupoids given by \( \mathcal{C} \mapsto \mathcal{C}^{[1]} \) where \( f^{[1]} \) denote the groupoid completion of the category \([1]\). This path object gives a notion of homotopies between maps of profinite groupoids. A levelwise application of this path object induces a path object in the category of operads in profinite groupoids. We denote by \( \pi\mathbf{Op}\mathsf{G} \) the category whose objects are operads in profinite groupoids and whose morphisms are homotopy classes of maps between them. The first main step in the proof is the following:

**Theorem (6.8).** The map \( \mathcal{G}T \to \text{End}(\mathcal{P}_{\mathcal{A}\mathcal{B}}) \) induces an isomorphism

\[
\mathcal{G}T \to \text{End}_{\pi\mathbf{Op}\mathsf{G}}(\mathcal{P}_{\mathcal{A}\mathcal{B}})
\]
One of the main issues with the profinite completion of spaces is that it does not preserve products. This led us to work with weak operads instead. A weak operad in a relative category with products $C$ is a homotopy algebra in $C$ over the algebraic theory $\Psi$ that controls operads.

In good cases, we construct a model category $WOpC$ encoding the homotopy category of weak operads in $C$. The profinite completion of spaces or groupoids induces a left Quillen functor $\hat{(-)} : WOpS \to WOpS$ which we take as our definition of the profinite completion of an operad. There is a similar profinite completion left Quillen functor for weak operads in groupoids.

There is an operadic nerve functor $N^{\Psi} : Op \to WOpS$ where $\Psi$ is the algebraic theory controlling operads. This operadic nerve is fully faithful and preserves the path object that exists on both sides. Thus we have an isomorphism

$$\text{End}_{WOpS}(\hat{P}aB) \cong \text{End}_{WOpS}(N^{\Psi}\hat{P}aB)$$

The endomorphisms of $N^{\Psi}\hat{P}aB$ in $Ho WOpG$ would coincide with the endomorphism in $\pi WOpG$ if $N^{\Psi}\hat{P}aB$ was cofibrant and fibrant. The weak operad $N^{\Psi}\hat{P}aB$ is probably not cofibrant, nevertheless, we prove the following:

**Theorem (7.2).** The composite

$$\hat{GT} \to \text{End}_{Op}(\hat{P}aB) \to \text{End}_{Ho WOpG}(N^{\Psi}\hat{P}aB)$$

is an isomorphism.

The last step is to lift this result about groupoid to a statement about spaces. This is not something that can be done in general because for a groupoid $C$, the natural map $\hat{B}C \to B\hat{C}$ (where $B$ denotes the classifying space functor) is in general not an equivalence. More precisely, the completion of the classifying space of $C$ could have non-trivial homotopy groups in degree higher than 1. Fortunately, this kind of pathology does not occur for the groupoids which appear in the operad $P\hat{P}aB$ and we can prove the following:

**Theorem (7.4).** There is an isomorphism of monoids

$$\text{End}_{Ho WOpG}(N^{\Psi}B\hat{P}aB) \cong \text{End}_{Ho WOpS}(N^{\Psi}B\hat{P}aB)$$

In particular, since $E_2 \simeq B\hat{P}aB$, we have an isomorphism

$$\hat{GT} \cong \text{End}_{Ho WOpS}(E_2)$$

There is an ambiguity on what the profinite completion of a space ought to be. For some authors, the profinite completion should be a pro-object in spaces. For other authors like Sullivan in $\text{[Sul74]}$, the profinite completion should be the inverse limit in spaces of that inverse system. More precisely, we have a right Quillen functor $|-|$ : $S \to \hat{S}$ which takes a profinite space to its inverse limit in spaces. The profinite completion of a space $X$ could be defined as $\hat{X}$ or as $|RX|$ where $R$ denotes a fibrant replacement in $\hat{S}$. In general the right derived functor of $|-|$ is not fully faithful. However, in the particular case that we are considering, we can prove the following variant of our main result:

**Theorem (7.12).** There is an isomorphism

$$\text{End}_{Ho WOpS}(\hat{E}_2) \cong \text{End}_{Ho WOpS}(|R\hat{E}_2|)$$

where $R\hat{E}_2$ denotes a fibrant replacement of $\hat{E}_2$ in $WOpS$. In particular, we also have an isomorphism

$$\hat{GT} \cong \text{End}_{Ho WOpS}(|R\hat{E}_2|)$$
1. A FEW FACTS ABOUT MODEL CATEGORIES

For future references, we recall a few useful facts about model categories.

**Cofibrant generation.**

1.1. **Definition.** Let $X$ be a cocomplete category and $I$ a set of maps in $X$.
   - The $I$-cell complexes are the smallest class of maps in $X$ containing $I$ and closed under pushout and transfinite composition.
   - The $I$-fibrations are the maps with the right lifting property against $I$.
   - The $I$-cofibrations are the maps with the left lifting property against the $I$-fibrations.

Recall that the $I$-cofibrations are the closure of the $I$-cell complexes under retract. One also shows that the $I$-fibrations are exactly the map with the right lifting property against the $I$-cofibrations. All these facts can be found in appendix A of [Lur09].

**Mapping spaces and adjunctions.** As any category with weak equivalences, a model category has a simplicial enrichment given by the hammock localization. We denote by $\text{Map}^h_{X}(X, Y)$ the space of maps from $X$ to $Y$ in the hammock localization of $X$ (see [DK80, 3.1.] for a definition of the hammock localization).

We denote by $\text{Map}_{X}(X, Y)$ the simplicial set of maps from $X$ to $Y$ whenever $X$ has a natural enrichment in simplicial sets. This space is related to the previous space by the following theorem:

1.2. **Theorem.** Let $X$ be a simplicial model category, let $X$ be a cofibrant object and $Y$ be a fibrant object, then there is an isomorphism in $\text{Ho}(S)$

$$\text{Map}_{X}(X, Y) \simeq \text{Map}^h_{X}(X, Y)$$

**Proof.** See [DK80, Corollary 4.7.]. □

A Quillen adjunction is an adjunction up to homotopy in the following sense:

1.3. **Theorem.** Let $F : X \rightleftarrows Y : U$ be a Quillen adjunction. Then we have an isomorphism in $\text{Ho}(S)$

$$\text{Map}^h_{Y}(LFX, Y) \simeq \text{Map}^h_{X}(X, RU Y)$$

**Left Bousfield localization.**

1.4. **Definition.** Let $X$ be a model category. A left Bousfield localization of $X$ is a model category $LX$ whose underlying category is $X$, whose cofibrations are the cofibrations of $X$ and whose weak equivalences contain the weak equivalences of $X$.

Tautologically, if $LX$ is a left Bousfield localization, the identity functor induces a Quillen adjunction

$$\text{id} : X \rightleftarrows LX : \text{id}$$

1.5. **Definition.** Let $X$ be a model category and $S$ be a class of maps in $X$. Then we say that an object $Z$ of $X$ is $S$-local if for any map $u : A \to B$ in $S$, the induced map

$$\text{Map}^h(B, Z) \to \text{Map}^h(A, Z)$$

is a weak equivalence.

Dually, if $K$ is a class of objects of $X$, we say that a map $u : A \to B$ is a $K$-weak equivalence if for all $Z$ in $K$, the induced map

$$\text{Map}^h(B, Z) \to \text{Map}^h(A, Z)$$

is a weak equivalence.
1.6. **Remark.** Note that our definition of $S$-local objects differs slightly from that of [Hir09]. An $S$-local object for Hirschhorn is an $S$-local object for us that is also fibrant.

Let $S$ be a class of maps in $X$. If it exists, we denote by $L_S X$ the left Bousfield localization of $X$ whose weak equivalences are the $K$-equivalences for $K$ the class of $S$-local objects.

It is usually hard to determine the fibrations of a Bousfield localization, however, the fibrant objects have a nice characterization:

1.7. **Proposition.** If $X$ is left proper and $L_S X$ exists, its fibrant objects are exactly the objects that are $S$-local and fibrant in $X$.

*Proof. This is proved in [Hir09, Proposition 3.4.1].∎*

1.8. **Proposition.** Let $X \to L_S X$ be a left Bousfield localization of a left proper model category $X$. Let $T$ be local with respect to the weak equivalences of $L_S X$ and $Z$ be any object. Then we have

$$\text{Map}^h_{L_S X}(Z,T) \simeq \text{Map}^h_X(Z,T)$$

*Proof. This is just theorem 1.3 applied to the Quillen adjunction $id : X \rightleftarrows L_S X : id$ □

We have two theorems of existence of left Bousfield localizations. One in the combinatorial case and one in the cocombinatorial case. We recall that a combinatorial model category is a model category that is cofibrantly generated and whose underlying category is presentable. We say that a model category is cocombinatorial if the opposite model category is combinatorial.

1.9. **Theorem.** Let $X$ be a left proper combinatorial model category, let $S$ be a set of maps in $X$, then there is a model structure on $X$ denoted $L_S X$ such that

- The cofibrations of $L_S X$ are the cofibrations of $X$.
- The fibrant objects of $L_S X$ are the objects of $X$ that are both $S$-local and fibrant in $X$.
- The weak equivalences in $L_S X$ are the $K$-equivalences for $K$ the class of $S$-local objects of $X$.

Moreover, this model structure is left proper and combinatorial. If $X$ is tractable and simplicial, then $L_S X$ is simplicial (for the same simplicial structure).

Before stating the second theorem, let us recall from [Bar10] that a cocombinatorial model category $X$ is said to be cocomplete if we can choose a set of generating fibration whose targets are fibrant.

1.10. **Theorem.** Let $X$ be a cocomplete and left proper model category. Let $K$ be a full subcategory of $X$ such that

- The category $K$ is a coaccessible and coaccessibly embedded subcategory of $X$.
- The category $K$ is stable under homotopy limits in $X$.
- The category $K$ is stable under weak equivalences.

Then there exists a model structure on $X$ denoted $L_K X$ such that

- The cofibrations of $L_K X$ are the cofibrations of $X$.
- The fibrant objects of $L_K X$ are the objects of $K$ that are fibrant in $X$.
- The weak equivalences are the $K$-local equivalences.

*Proof. The dual statement is proved in [Bar10, Theorem 5.22].□*
2. Pro categories

In this section, we recall a few basic facts about pro-categories.

2.1. Definition. A category $I$ is cofiltered if for any finite category $K$ with a map $f : K \to I$, there exists an extension of $f$ to a cocone $K^\to \to I$.

For any small category $C$, one can form the category $\text{Pro}(C)$ by formally adding cofiltered limits to $C$. More explicitly, the objects of $\text{Pro}(C)$ are pairs $(I, X)$ where $I$ is a cofiltered small category and $X : I \to C$ is a functor. We usually write $\{X_i\}_{i \in I}$ for an object of $\text{Pro}(C)$. The morphisms are given by

$$\text{Pro}(C)(\{X_i\}_{i \in I}, \{Y_j\}_{j \in J}) = \lim_{j \in J} \text{colim}_{i \in I} C(X_i, Y_j)$$

The category $\text{Pro}(C)$ can be alternatively defined as the opposite of the full subcategory of $\text{Fun}(C, \text{Set})$ spanned by objects that are filtered colimits of representable functors. The equivalence with the previous definition comes from identifying $\{X_i\}_{i \in I}$ with the colimit of the diagram

$$i \mapsto C(X_i, -)$$

seen as an object of $\text{Fun}(C, \text{Set})^{\text{op}}$.

Note that there is an obvious fully faithful inclusion $C \to \text{Pro}(C)$ sending $X \in C$ to the functor $C \to \text{Set}$ represented by $X$. Moreover, it can be shown that $\text{Pro}(C)$ has all cofiltered limits. In particular, if $i \mapsto X_i$ is a cofiltered diagram in $C$, its inverse limit in $\text{Pro}(C)$ is $\{X_i\}_{i \in I}$.

The universal property of the pro-category can then be expressed in the following theorem.

2.2. Theorem. Let $C$ be a small category and $D$ be a category with cofiltered limits. Let $\text{Fun}'(\text{Pro}(C), D)$ be the category of functors $\text{Pro}(C) \to D$ which commute with cofiltered limits. Then the restriction functor

$$\text{Fun}'(\text{Pro}(C), D) \to \text{Fun}(C, D)$$

is an equivalence of categories.

2.3. Proposition. If $C$ is a small finitely complete category, then $\text{Pro}(C)$ is a copresentable category (i.e. its opposite is a presentable category).

Proof. The category $\text{Pro}(C)^{\text{op}}$ is equivalent to $\text{Ind}(C^{\text{op}})$ and $C^{\text{op}}$ has all finite colimits. Therefore $\text{Ind}(C^{\text{op}})$ is presentable. □

If $C$ has all finite limits, we have a nice characterization of the filtered colimits of representable functors.

2.4. Proposition. If $C$ has all finite limits, then a functor $C \to \text{Set}$ is a filtered colimit of representable functors if and only if it preserves finite limits.

Proof. Clearly all representable functors $C \to \text{Set}$ preserve finite limits. In the category of sets finite limits commute with filtered colimits. This implies that any filtered colimit of representable functors preserves finite limits.

Conversely, as any covariant functor, $F$ is the colimit of the composite

$$C^{\text{op}}_{/F} \to C^{\text{op}} \to \text{Fun}(C, \text{Set})$$

where the second map is the Yoneda embedding. Thus it suffices to prove that $C^{\text{op}}_{/F}$ is filtered if $F$ preserves finite limits.

Let $I$ be a finite category and $u : I \to C^{\text{op}}_{/F}$ be a diagram in $C^{\text{op}}_{/F}$. In other words, $u$ is the data of a functor $v : I \to C^{\text{op}}$ with a map to the constant functor $I \to \text{Fun}(C, \text{Set})$ with value $F$. Since
$F$ commutes with finite limits, the colimit of $v$ in $C^{op}$ (which is the limit of $v^{op} : I^{op} \to C$) has a natural map to $F$ which makes it a cocone for $u : I \to C^{op}$. \hfill \square

2.5. Remark. In other words, a functor $F : C \to \text{Set}$ preserves finite limits if and only if has an extension $\text{Pro}(C) \to \text{Set}$ which is a representable functor. Moreover, any two choices of representing objects are canonically isomorphic. The situation can be summarized by saying that covariant functors that preserve finite limits are pro-representable.

Profinite sets and groups.

2.6. Definition. Let $F$ be the category of finite sets. The category $\hat{\text{Set}}$ of profinite sets is defined to be the category $\text{Pro}(F)$.

Since the category $F$ has all finite limits, the category $\hat{\text{Set}}$ is the opposite of the category of finite limit preserving functors $F \to \text{Set}$. There is a more concrete way of understanding the category $\hat{\text{Set}}$.

2.7. Proposition. The category $\hat{\text{Set}}$ is equivalent to the category of compact Hausdorff totally disconnected spaces and continuous maps.

The functor from $\hat{\text{Set}}$ to topological spaces is obtained by first considering a cofiltered diagram in finite sets as a cofiltered diagram in discrete topological spaces and then take its inverse limit in the category topological space.

Similarly, we can consider the category $\hat{\text{Grp}}$ of finite groups and form the category

$$\hat{\text{Grp}} := \text{Pro}(\hat{\text{Grp}})$$

2.8. Proposition. The category $\hat{\text{Grp}}$ is equivalent to the category of group objects in $\hat{\text{Set}}$. Equivalently, the category $\hat{\text{Grp}}$ is the category of topological groups whose underlying topological space is compact Hausdorff and totally disconnected.

There is a functor

$$\hat{\text{Grp}} \to \text{Grp}$$

which sends a profinite group to its underlying group (forgetting the topology). This functor has a left adjoint $G \mapsto \hat{G}$ called profinite completion.

2.9. Definition. The profinite completion of a discrete group $G$ denoted $\hat{G}$ is the inverse limit of the diagram of topological groups

$$N \mapsto G/N$$

where $N$ runs over the poset of normal finite index subgroups of $G$ and $G/N$ is given the discrete topology.

3. Profinite groupoids

We first introduce a few useful notations.

A groupoid, is a small category in which all morphisms are invertible. We denote by $G$ the category of groupoids and by $\text{Ob} : G \to \text{Set}$ the functor sending a groupoid to its set of objects. This functor has a left adjoint $\text{Disc}$ which sends a set $S$ to the discrete groupoid on that set of objects (a groupoid is discrete if it has only identities as morphisms) and a right adjoint $\text{Codisc}$ which sends a set $S$ to the groupoid $\text{Codisc}(S)$ whose set of objects is $S$ and with exactly one morphisms between any two objects. We do not usually write the functor $\text{Disc}$ and see a set as a groupoid via this functor.
Given a set $S$ with a right action by a group $G$, we denote by $S ∋ G$ the translation groupoid. This is the groupoid whose set of objects is $S$. The set of morphisms from $s$ to $t$ is the set of elements of $G$ such that $s.g = t$. In particular, $∗ ∋ G$ is a groupoid whose nerve is the classifying space of $G$.

Given a set $S$ and a group $G$, we denote by $G[S]$ the groupoid $G × \text{Codisc}(S)$. Note that any connected groupoid is non-canonically isomorphic to $G[S]$ with $S$ the set of objects and $G$ the group of automorphisms of a chosen object. A general groupoid $C$ is isomorphic to a disjoint union $\sqcup_{u \in \pi_0(C)} G[u][S_u]$ indexed by the set of connected component of $C$.

**Profinite groupoids.** In this section, we construct a model structure on the category of profinite groupoids (i.e. the pro-category of the category of finite groupoids) that is analogous to Quick’s model structure on $\tilde{S}$.

We say that a groupoid is a finite groupoid if its set of morphisms is finite. Note that this also implies that the set of objects is finite. We denote by $fG$ the full subcategory of $G$ spanned by the finite groupoids. We denote by $\hat{G}$ the pro-category of $fG$.

3.1. **Definition.** Let $A$ be a finite groupoid and $S$ be a finite set. The $0$-th cohomology set of $A$ with coefficients in $S$ is the set of maps $u : \text{Ob}(A) → S$ that are constant on isomorphisms classes.

Let $G$ be a finite group. We define the set $Z^1(A, G)$ to be the set of maps $u : \text{Ar}(A) → G$ such that

$$u(f \circ g) = u(f)u(g)$$

We define $B^1(A, G)$ to be the set of maps $φ : \text{Ob}(A) → G$. The set $B^1(A, G)$ is a product of copies of $G$ and as such it has a group structure. There is a right action of $B^1(A, G)$ on $Z^1(A, G)$. Given $u$ in $Z^1(A, G)$ and $φ$ in $B^1(A, G)$, we define $u.φ$ in $Z^1(A, G)$ by the following formula:

$$(u.φ)(f) = φ(t(f))^{-1}u(f)φ(s(f))$$

where $s$ and $t$ send a morphism in $A$ to its source and target.

3.2. **Definition.** The first cohomology set of $A$ with coefficients in $G$ denoted $H^1(A, G)$ is the quotient $Z^1(A, G)/B^1(A, G)$.

Now we give an alternative definition of $H^1(A, G)$.

We write $I[1]$ for the codiscrete groupoid on two objects. Equivalently, $I[1]$ is the groupoid representing the functor $G → \text{Set}$ sending $A$ to $\text{Ar}(A)$. For $G$ a finite group, we can form the $G$-set $G^c$ which is $G$ with the right action given by conjugation:

$$g.h := h^{-1}gh$$

We observe that $Z^1(A, G) = fG(A, ∗ ∋ G)$.

There is a map $G^c ∋ G → (∗ ∋ G)^2$. On objects, it is the unique map and it sends a conjugation $k^{-1}gk = h$ to $g$ and $h$ respectively. This map represents a pair of parallel maps

$$fG(A, G^c ∋ G) \Rightarrow fG(A, ∗ ∋ G)$$

for any finite groupoid $A$.

3.3. **Proposition.** The coequalizer of

$$fG(A, G^c ∋ G) \Rightarrow Z^1(A, G)$$

is isomorphic to $H^1(A, G)$.

**Proof.** This is a trivial computation. □
3.4. Definition. Let \( A = \{ A_i \}_{i \in I} \) be a profinite groupoid. We define the 0-th cohomology set of \( A \) with coefficients in a finite set \( S \) by the formula:
\[
H^0(A, S) = \text{colim}_I H^0(A_i, S)
\]
similarly, we define the first cohomology set of \( A \) with coefficients in a finite group \( G \) by the formula
\[
H^1(A, G) = \text{colim}_I H^1(A_i, G)
\]

3.5. Lemma. If \( i \mapsto S_i \) is a filtered colimit of sets and \( i \mapsto G_i \) is a filtered colimit of groups and if there is an action \( S_i \times G_i \to S_i \) which is functorial in \( i \), then, the obvious map
\[
\text{colim}_i (S_i/G_i) \to (\text{colim}_i S_i)/(\text{colim}_i G_i)
\]
is an isomorphism.

Proof. For each \( i \), we have a coequalizer diagram
\[
S_i \times G_i \rightrightarrows S_i \to S_i/G_i
\]
Since filtered colimits commute with coequalizers and filtered colimits in groups are reflected by the forgetful functor to \( \text{Set} \), we are done.

For \( A = \{ A_i \}_{i \in I} \) a profinite groupoid, we can define the set \( Z^1(A,G) \) by the formula
\[
Z^1(A,G) = \text{colim}_I Z^1(A_i,G)
\]
and we can define \( B^1(A,G) \) by a similar colimit. According to the previous lemma, we have:
\[
H^1(A,G) := \text{colim}_I H^1(A_i,G) \cong (\text{colim}_I Z^1(A_i,G))/(\text{colim}_I B^1(A_i,G)) \cong Z^1(A,G)/B^1(A,G)
\]

3.6. Proposition. Let \( S \) be a finite set and \( G \) be a finite group. For any profinite groupoid \( A \), there are isomorphisms:
\[
H^0(A, S) = \hat{\mathcal{G}}(A, S)
\]
\[
Z^1(A, G) = \hat{\mathcal{G}}(A, * / G)
\]
\[
B^1(A, G) = \hat{\mathcal{G}}(A, G)
\]

Proof. Each formula is true if \( A \) is a finite groupoid. Moreover, by definition of the hom sets in a pro-category, we have \( \hat{\mathcal{G}}(A, S) = \text{colim}_I f\mathcal{G}(A_i, S) = H^0(A, S) \) and similarly in the other two cases.

3.7. Proposition. Let \( A : I \to \hat{\mathcal{G}} \) be a cofiltered diagram with value in profinite groupoids. Let \( S \) be a finite set, then the map
\[
\text{colim}_I H^0(A_i, S) \to H^0(\lim A_i, S)
\]
is an isomorphism. The obvious analogous statement holds for \( H^1 \).

Proof. The case of \( H^0 \) is easy since \( H^0(A, S) = \hat{\mathcal{G}}(A, S) \) and \( S \) being an object of \( f\mathcal{G} \) is cosmall in \( \hat{\mathcal{G}} = \text{Pro}(f\mathcal{G}) \). Similarly, \( Z^1(\_, G) \) and \( B^1(\_, G) \) are representable by objects of \( f\mathcal{G} \) and thus they send cofiltered limits to filtered colimits. The result then follows from lemma 3.5.

3.8. Definition. We say that a map \( u : A \to B \) is \( \hat{\mathcal{G}} \) is a weak equivalence if for all finite set \( S \),
\[
u^* : H^0(B, S) \to H^0(A, S)
\]
is an isomorphism and for all finite group \( G \)
\[
u^* : H^1(B, G) \to H^1(A, G)
\]
is an isomorphism.
3.9. **Proposition.** Let $I$ be a cofiltered category and $A : I \to f\mathcal{G}$ and $B : f\mathcal{G} \to f\mathcal{G}$ be two functors and $u : A \to B$ be a natural transformation such that for all $i$, the map $u_i : A_i \to B_i$ is an equivalence of groupoid. Then the maps $A \to B$ is an equivalence in $\hat{\mathcal{G}}$.

**Proof.** Let $S$ be a finite set. For all $i$, the map

$$H^0(B_i, S) \to H^0(A_i, S)$$

is an isomorphism. Therefore, the map:

$$H^0(B, S) \to H^0(A, S)$$

is an isomorphism as a colimit of isomorphism.

A similar proof holds for the first cohomology sets. \(\square\)

3.10. **Proposition.** Weak equivalences in $\hat{\mathcal{G}}$ are stable under cofiltered limits.

**Proof.** The proof is similar to the proof of the previous proposition and uses proposition 3.7. \(\square\)

There is a functor Disc : $F \to f\mathcal{G}$ sending the set $S$ to the discrete groupoid on that set of objects.

This functor has a left adjoint $\pi_0 : f\mathcal{G} \to F$. We can extend both functors to the pro-category by imposing that they commute with cofiltered limits and we get an adjunction:

$$\pi_0 : \hat{\mathcal{G}} \rightleftarrows \hat{\mathcal{G}} : \text{Disc}$$

3.11. **Proposition.** Let $f : A \to B$ be a weak equivalence in $\hat{\mathcal{G}}$. Then $\pi_0(f)$ is an isomorphism.

**Proof.** Let $S$ be a finite set. Then we have

$$H^0(A, S) \cong \hat{\mathcal{G}}(A, S) \cong \hat{\text{Set}}(\pi_0(A), S)$$

Thus, the map $\pi_0(A) \to \pi_0(B)$ induces an isomorphism when mapping to a finite set. This is enough to insure that this is an isomorphism of profinite sets. \(\square\)

**Construction of the model structure.** We define two sets of arrows $P$ and $Q$ in $f\mathcal{G}$.

Let us pick a set $S$ of finite sets containing a representative of each isomorphism class of finite set. Let $\mathcal{G}$ be the set of groups whose underlying set is in $S$.

The set $P$ is the set of maps of the form:

$$G \underset{G}{\rightarrow} * \underset{G}{\rightarrow} G, G^c \underset{G}{\rightarrow} * \underset{G}{\rightarrow} S, S \rightarrow S, S \rightarrow S \times S$$

where $G$ is any finite group in $\mathcal{G}$ and $S$ is any finite set in $S$.

The set $Q$ is the set of maps:

$$G \underset{G}{\rightarrow} *$$

where $G$ is any finite group in $\mathcal{G}$.

We can now state the main theorem of this section:

3.12. **Theorem.** The category $\hat{\mathcal{G}}$ has a cocombinatorial model structure in which the cofibrations (resp. trivial cofibrations) are the $Q$-projective maps (resp. $P$-projective maps) and the weak equivalences are as in definition 3.8.
Proof. We apply the dual of [Hir09, Theorem 11.3.1].

(1) The objects $* \sslash G$ and $S \times S$ are cosmall.

(2) The $Q$-cocell complexes are weak equivalences. Since weak equivalences are stable under cofiltered limits by proposition 3.10, it suffices to check that any pullback of a map in $Q$ is a weak equivalence. Let $A = \{A_i\}_{i \in I}$ be an object of $\hat{G}$, then the map

$$A \times G \sslash G \to A$$

is the limit in $\hat{G}$ of the maps

$$A_i \times G \sslash G \to A_i$$

Therefore, it is a weak equivalences in $\hat{G}$ by proposition 3.9.

(3) The maps in $Q$ are $P$-cocell complexes.

(4) The $P$-projective maps are $Q$-projective. Indeed, the $P$-projective maps are those with the left lifting property against the $P$-cocell complexes. In particular, according to the previous paragraph, they have the left lifting property against the maps in $Q$ and hence are $Q$-projective.

(5) The $P$-projective maps are weak equivalences. Let $u : A \to B$ be a $P$-projective map. The left lifting property against the map $S \to *$ tells us that

$$u^* : H^0(B, S) \to H^0(A, S)$$

is surjective.

We clearly have the isomorphism of functors $H^0(-, S \times S) \cong H^0(-, S)^2$. The left lifting property against $S \to S \times S$ tells us that

$$H^0(B, S) \to H^0(A, S) \times_{H^0(A, S)^2} H^0(B, S)^2$$

is surjective which is saying that two classes in $H^0(B, S)$ mapping to the same class in $H^0(A, S)$ must come from a single class in $H^0(B, S)$ via the diagonal map. This is equivalent to saying that

$$u^* : H^0(B, S) \to H^0(A, S)$$

is injective.

The left lifting property against $* \sslash G \to *$ is equivalent to saying that

$$u^* : Z^1(B, G) \to Z^1(A, G)$$

is surjective which implies that $H^1(B, G) \to H^1(A, G)$ is surjective.

The left lifting against $G^c \sslash G \to (* \sslash G)^2$ says that if two elements of $Z^1(B, G)$ become equivalent when pull-backed to $A$, then they must already be equivalent in $Z^1(B, G)$. This is exactly saying that the map

$$H^1(B, G) \to H^1(A, G)$$

is injective.

(6) The $Q$-projective maps that are weak equivalences are $P$-projective. Let $u : A \to B$ be a map that is $Q$-projective and a weak equivalence. Being a $Q$-cofibration is equivalent to saying that for all finite group $G$, the map

$$u^* : B^1(B, G) \to B^1(A, G)$$

is surjective.

• The fact that $A \to B$ is an equivalence implies that $\pi_0(A) \to \pi_0(B)$ is an isomorphism by proposition 3.11. The lifting property against $S \to *$ and $S \to S \times S$ is then immediate.
We also define a set \( \text{Codisc}(S) \) which is injective. This implies that \( u^*(z) \) represents the base point of \( H^1(A,G) \) which means that \( z = 1.l \) for some \( l \) in \( B^3(B,G) \). It is not necessarily true that \( u^*(l) = k \). However, from the equation \( u^*(z) = 1.k \), we find that the function \( u^*(l)^{-1}k \) is in \( H^0(A,G) \). Since \( H^0(B,G) = H^0(A,G) \), there exists \( m \in H^0(B,G) \) such that \( u^*(m) = u^*(l)^{-1}k \). Now we see that the element \( lm \) in \( B^1(B,G) \) maps to \( k \) in \( B^1(A,G) \) and to \( 1.lm \) in \( Z^1(B,G) \) but \( 1.lm = 1.l = z \) because \( m \) is locally constant.

Finally, we prove that \( u \) has the left lifting property with respect to \( G \parallel G \rightarrow (\ast \parallel G)^2 \). According to the previous paragraph this is just saying that the map \( H^1(B,G) \rightarrow H^1(A,G) \) is injective.

\[ \square \]

We also define a set \( Q' \) of arrows in \( fG \). This is the set of maps:

\[ \text{Codisc}(S) \rightarrow \ast \]

where \( S \) is a non-empty finite set in \( S \).

3.13. Lemma. The essential image of \( Q \) and \( Q' \) in \( fG^{[1]} \) are the same.

**Proof.** In other word, we are claiming that any map in \( Q \) is isomorphic to a map in \( Q' \) and vice-versa. The reason this is true is that \( G \parallel G \) is isomorphic to the groupoid \( \text{Codisc}(G) \) where \( G \) is just seen as a set. Conversely, if \( S \) is non-empty, the groupoid \( \text{Codisc}(S) \) is isomorphic to \( G \parallel G \) for any group \( G \) whose underlying set is \( S \).

This lemma implies that we could have used \( Q' \) instead of \( Q \) in the previous theorem and we would have obtained the same model structure on \( \mathcal{G} \).

3.14. Proposition. In \( \mathcal{G} \) a map is a cofibration if and only if it is injective on objects.

**Proof.** The adjunction

\[ \text{Ob} : fG \rightleftarrows \mathcal{F} : \text{Codisc} \]

induces an adjunction

\[ \text{Ob} : \mathcal{G} \rightleftarrows \text{Set} : \text{Codisc} \]

By adjunction, a map is injective on objects, if and only if it has the left lifting property against \( \text{Codisc}(S) \rightarrow \ast \) for any non-empty finite set \( S \). By lemma 3.13, this is equivalent to being a cofibration.

\[ \square \]
3.15. **Corollary.** The model category \( \hat{\mathcal{G}} \) is left proper.

*Proof.* Any model category in which all objects are cofibrant is left proper. \( \square \)

**Profinite completion of groupoids.** Let \( \mathcal{G} \) be the category of groupoids. Let \( \hat{\mathcal{G}} \) be the category of profinite groupoids.

Let \( C \) be any groupoid, then the functor \( D \mapsto \mathcal{G}(C, D) \) from finite groupoids to sets preserves finite limits, therefore it is represented by an object \( \hat{C} \) in \( \hat{\mathcal{G}} \) by remark 2.5. We now give a more explicit description of this completion functor.

3.16. **Definition.** Let \( C \) be a groupoid. An equivalence relation on \( C \) is an equivalence relation on \( \text{Ob}(C) \) and an equivalence relation on \( \text{Mor}(C) \) such that there exists a morphism \( p : C \to E \) in \( \mathcal{G} \) which is surjective on objects and morphisms and with the property that two objects (resp. morphisms) of \( C \) are equivalent if and only if they are sent to the same object (resp. morphism) of \( E \).

If \( R \) is an equivalence relation on \( C \), we denote by \( C/R \) the groupoids whose objects are \( \text{Ob}(C)/R \) and morphisms are \( \text{Mor}(C)/R \).

3.17. **Proposition.** Let \( f : C \to D \) be a morphism of groupoids. Then there is an equivalence relation on \( C \) for which two objects (resp. morphisms) of \( C \) are equivalent if and only if they are sent to the same object (resp. morphism) of \( D \) by \( f \).

*Proof.* We can just define \( E \) to be the groupoid whose objects (resp. morphisms) are the objects of \( D \) that are in the image of \( f \). Then the map \( f \) factors as

\[
C \xrightarrow{p} E \to D
\]

where the map \( p \) is surjective on objects and morphisms. It is clear that the equivalence relation induced by \( f \) is the equivalence relation induced by \( p \). \( \square \)

In the following, we call this equivalence relation the kernel of \( f \) and denote it by \( \ker(f) \). Note that if \( C = * \rtimes \mathcal{G} \) is a group, the data of an equivalence relation on \( C \) is exactly the data of a normal subgroup of \( \mathcal{G} \). Moreover, if \( f : \mathcal{G} \to \mathcal{H} \) is a group homomorphism, then its kernel in the group theoretic sense coincides with the kernel of the induced map \( * \rtimes \mathcal{G} \to * \rtimes \mathcal{H} \).

3.18. **Definition.** Let \( (G, R) \) be a groupoid with an equivalence relation. We say that \( R \) is cofinite if \( G/R \) is in \( \mathcal{G} \).

The set of cofinite equivalence relations on \( G \) is a cofiltered poset with respect to inclusion. Therefore, we can consider the object of \( \hat{\mathcal{G}} \) given by \( \{G/R\}_R \text{cofinite} \). The following proposition shows that this is a model for \( \hat{\mathcal{G}} \).

3.19. **Proposition.** For any \( D \) a finite groupoid, there is an isomorphism

\[
\hat{\mathcal{G}}(\{C/R\}_R \text{cofinite}, D) \cong \mathcal{G}(C, D)
\]

which is natural in \( D \).

*Proof.* By definition of \( \hat{\mathcal{G}} \), we have

\[
\hat{\mathcal{G}}(\{C/R\}_R \text{cofinite}, D) = \colim_{R \text{cofinite}} f\mathcal{G}(C/R, D)
\]

On the other hand, since any morphism \( C \to D \) must have a cofinite kernel, we see that

\[
\mathcal{G}(C, D) \cong \colim_{R \text{cofinite}} f\mathcal{G}(C/R, D)
\]

\( \square \)
3.20. **Remark.** As we have said before, an equivalence relation on a groupoid of the form \( \ast \sslash G \) is exactly the data of a normal subgroup of \( G \). This equivalence relation is moreover cofinite if and only if the corresponding normal subgroup is of finite index. Hence we see from the previous proposition that 
\[
\ast \sslash G \cong \ast \sslash \hat{G}
\]

**Quillen adjunction.** The category \( G \) of groupoids has a model structure in which the cofibrations are the maps that are injective on objects, weak equivalences are the fully faithful and essentially surjective maps and the fibrations are the isofibrations. A construction can be found in section 6 of [Str01]

This model structure is combinatorial, proper and simplicial. We refer to this model structure as the canonical model structure.

3.21. **Lemma.** The maps in \( P \) seen as maps of \( G \) are fibrations in the canonical model structure on \( G \). Similarly, the maps in \( Q \) are trivial fibrations in the canonical model structure.

**Proof.** The trivial fibrations in the canonical model structure are the maps that are fully faithful and surjective on objects. It is thus obvious that the maps of \( Q \) are trivial fibrations. The fibrations in the canonical model structure are the isofibrations, that is the map with the right lifting property against the two inclusions \([0] \to I[1] \). It is obvious that the maps \( S \to \ast \) and \( S \to S \times S \), \( G \sslash G \to \ast \sslash G \) and \( \ast \sslash G \to \ast \) have this property. The map \( G^2 \sslash G \to (\ast \sslash G)^2 \) has this property because it can alternatively be described as the map 
\[
(\ast \sslash G)^{[1]} \to (\ast \sslash G)^{[0] \sqcup [0]}
\]
induced by the inclusion \([0] \sqcup [0] \to I[1] \). Since this last map is a cofibration in \( G \) and \( \ast \sslash G \) is fibrant in \( G \) (as is any object) and \( G \) is a cartesian closed model category, we are done. \( \square \)

3.22. **Proposition.** The profinite completion functor 
\[
\hat{\ast} : G \to \hat{G}
\]
is a Quillen left functor.

**Proof.** First, this functor has a left adjoint \( \lvert \ast \rvert \) which sends a profinite groupoid \( \{C_i \}_{i \in I} \) to \( \lim_I C_i \) where the limit is computed in the category \( G \). It suffices to show that the functor \( \lvert \ast \rvert \) sends generating fibrations to fibrations and generating trivial fibrations to trivial fibrations but this is exactly the content of lemma 3.21. \( \square \)

In particular, since all objects are cofibrant in \( G \), the profinite completion functor preserves weak equivalences.

3.23. **Proposition.** Let \( C \) and \( D \) be two groupoids with a finite set of objects. The map 
\[
\hat{C} \times \hat{D} \to \hat{C} \times \hat{D}
\]
induced by the two projections \( \hat{C} \times \hat{D} \to \hat{C} \) and \( \hat{C} \times \hat{D} \to \hat{D} \) is an isomorphism.

**Proof.** If \( R \) is an equivalence relation on \( C \) and \( S \) is an equivalence relation on \( D \), we denote by \( R \times S \) the equivalence relation which is the kernel of the map 
\[
C \times D \to (C/R) \times (D/S)
\]
The profinite groupoid \( \hat{C} \times \hat{D} \) is the inverse limit of \( (C \times D)/(R \times S) \) taken over all pairs \( (R, S) \) of cofinite equivalence relations on \( C \) and \( D \). On the other hand \( \hat{C} \times \hat{D} \) is the inverse limit of \( (C \times D)/T \) taken over all cofinite equivalence relations \( T \) on \( C \times D \). Thus, in order to prove the proposition,
it suffices to prove that any cofinite equivalence relation $T$ of $C \times D$ is coarser than an equivalence relation of the form $R \times S$ with $R$ and $S$ cofinite equivalence relations of $C$ and $D$ respectively.

Let $T$ be a cofinite equivalence relation on $C \times D$. We can consider the composite

$$C \to \coprod_{\text{Ob}(D)} C \times [0] \to \coprod_{\text{Ob}(D)} C \times D \to \coprod_{\text{Ob}(D)} (C \times D)/T$$

where the first map is the diagonal map, the third map is the projection and the factor indexed by $X$ of the second map is just the product of $\text{id}_C$ with the map $[0] \to D$ picking up the object $X$.

The kernel of this map is a cofinite equivalence relation on $C$ that we denote $T_C$. Two objects $x$ and $y$ of $C$ are $T_C$-equivalent if and only if for all $z$ in $D$, $(x, z)$ is $T$-equivalent to $(y, z)$. Likewise, two arrows $u$ and $v$ of $C$ are $T_C$-equivalent if and only if $(u, \text{id}_z)$ is $T$-equivalent to $(v, \text{id}_z)$ for any object $z$ of $D$. It is a cofinite equivalence relation because it is the kernel of a map with finite target (this is where we use the finiteness of the set of objects of $D$). We can define a cofinite equivalence relation $T_D$ on $D$ in a similar fashion.

We claim that $T_C \times T_D$ is finer than $T$ indeed, if $(u, v)$ is pair of arrows that is $T_C \times T_D$-equivalent to $(u', v')$, then $(u, \text{id}_{\text{im}(v)})$ is $T$-equivalent to $(u', \text{id}_{\text{im}(v)})$ and similarly $(\text{id}_{\text{im}(u)}, v)$ is $T$-equivalent to $(\text{id}_{\text{im}(u)}, v')$. Thus $(u, v) = (u, \text{id}_{\text{im}(v)}) \circ (\text{id}_{\text{im}(u)}, v)$ is $T$-equivalent to $(u', v') = (u', \text{id}_{\text{im}(v)}) \circ (\text{id}_{\text{im}(u)}, v')$.

3.24. Corollary. Let $S$ be a finite set and $G$ be a group. Then

$$G[S] \cong \tilde{G}[S]$$

Proof. The groupoid $G[S]$ is the product $(\ast \sslash G) \times \text{Codisc}(S)$. We have already observed that $\ast \sslash G \cong \ast \sslash \tilde{G}$. On the other hand, since $S$ is finite, the groupoid $\text{Codisc}(S)$ is finite. The result then follows from proposition 3.23.

Since profinite completion commutes with coproducts, this corollary gives a formula for profinite completion of groupoids with a finite set of objects in terms of profinite completion of groups.

More on weak equivalences. For $C$ a groupoid, we denote by $C^{[1]}$ the groupoid of functors from $I^{[1]}$ to $C$. For $C = \{C_i\}_{i \in I}$ a object of $\hat{G}$, we denote by $C^{[1]}$ the object $\{C^{[1]}_i\}_{i \in I}$. Note that $C^{[1]}$ is equipped with two maps $e_0$ and $e_1$ to $C$ given by the evaluation at the two objects of $I^{[1]}$.

We say that two maps $f, g : C \to D$ in $G$ or $\hat{G}$ are homotopic if there exists a map $H : C \to D^{[1]}$ such that $e_0 \circ H = f$ and $e_1 \circ H = g$. We denote by $\pi G$ (resp. $\pi \hat{G}$) the category whose objects are the objects of $G$ (resp. $\hat{G}$) and whose morphisms are the homotopy classes of morphisms.

3.25. Proposition. Let $S$ be a finite set and $A$ be an object of $\hat{G}$, then

$$H^0(A, S) = \pi \hat{G}(A, S)$$

Similarly, let $G$ be a finite group, then

$$H^1(A, G) = \pi \hat{G}(A, \ast \sslash G)$$

Proof. Clearly we have $\pi \hat{G}(\{A_i\}_{i \in I}, S) = \text{colim}_i \pi \hat{G}(A_i, S)$ and similarly $\pi \hat{G}(\{A_i\}_{i \in I}, \ast \sslash G) = \text{colim}_i \pi \hat{G}(A_i, \ast \sslash G)$, thus, it suffices to check these formulas for $A$ an object of $J G$.

We do the case $H^1(A, G)$. The other one is similar and easier. A trivial computation shows that $(\ast \sslash G)^{[1]}$ is isomorphic to $G^{[1]} \sslash G$ and that $(e_0, e_1) : G^{[1]} \sslash G \to \ast \sslash G$ is exactly the map used in the definition of $H^1(A, G)$. Thus the coequalizer defining $H^1(A, G)$ is the coequalizer defining $\pi \hat{G}(A, \ast \sslash G)$. □
3.26. Proposition. A map \( u : A \to B \) is a weak equivalence in \( \hat{G} \) if and only if for any finite groupoid \( C \), the induced map

\[
\pi \hat{G}(B, C) \to \pi \hat{G}(A, C)
\]

is an isomorphism.

Proof. Since \( S \) and \( * \parallel G \) with \( S \) a finite set and \( G \) a finite group are finite groupoids, we see that this is a sufficient condition for \( u \) to be a weak equivalence.

Let us prove the reverse implication. For \( C \) a finite groupoid, we say that \( u \) is a \( C \)-equivalence if the map

\[
\pi \hat{G}(B, C) \to \pi \hat{G}(A, C)
\]

is an isomorphism. Thus our goal is to prove that if \( u \) map in \( G \) under finite products and retracts. The class of such groupoids is also stable under weak equivalences all finite groupoid \( C \).

Let us consider a coproduct \( D \sqcup E \) of finite groupoids. Let \( Z = D \times E \times \{0, 1\} \). We pick an object \( d_0 \) in \( D \) and \( e_0 \) in \( E \). There is a map \( D \sqcup E \to Z \) sending \( d \) to \( (d, e_0, 0) \) and \( e \) to \( (d_0, e, 1) \). There is a map \( Z \to D \sqcup E \) sending \( (d, e, 0) \) to \( d \) and \( (d, e, 1) \) to \( e \). These two maps make \( D \sqcup E \) into a retract of \( Z \). Thus, the class of groupoids \( C \) for which \( u \) is a weak equivalence is stable under finite coproducts.

This concludes the proof since any finite groupoid is weakly equivalent to a groupoid of the form \( \sqcup_{x \in X}(\ast \parallel G_x) \) where \( X \) is a finite set and the \( G_x \) are finite groups.

3.27. Corollary. Let \( u : A \to B \) be a map between finite groupoid. Then \( u \) is a weak equivalence in \( G \) if and only if it is a weak equivalence in \( \hat{G} \).

Proof. This follows from the previous proposition, Yoneda’s lemma in \( \pi fG \) and the fact that the weak equivalences in \( fG \) are exactly the homotopy equivalences (i.e. the maps that are sent to isomorphisms in \( \pi G \)).

Simplicial enrichment. There is a pairing

\[
\hat{G} \times G \to \hat{G}
\]

sending \( (A, C) \) to \( A \times \hat{C} \). We will now prove that this is a Quillen bifunctor. The first step is to prove that this is a left adjoint in both variables.

The compact objects of \( G \) are the groupoids \( C \) with \( \text{Ob}(C) \) finite and \( C(x, x) \) a finitely presented group for each \( x \), in particular, the objects of \( fG \) are compact. We denote by \( G_f \) the full subcategory spanned by compact objects. Note that we have an equivalence of categories \( \text{Ind}(G_f) \simeq G \).

If \( C \) is a compact object in \( G \) and \( D \) is an object of \( fG \), then \( D^C \) is in \( fG \). Indeed, \( C \) can be written as a finite disjoint union of groupoids of the form \( G[S] \) with \( S \) finite and \( G \) finitely presented. Thus we are reduced to proving that there are only finitely many maps from a finitely presented group to a finite group which is straightforward.

The functor \( (C, D) \mapsto D^C \) from \( G_f^{\text{op}} \times fG \to fG \) preserves finite limits in both variables. Hence, it extends uniquely into a functor

\[
G^{\text{op}} \times \hat{G} \to \hat{G}
\]
which preserves limits in both variable. We still denote this functor by \((C, D) \mapsto D^C\).

There is another functor \(\text{map}(-, -) : \hat{G}^{\text{op}} \times \hat{G} \to G\) given by the formula

\[
\text{map}(\{C_i\}_{i \in I}, \{D_j\}_{j \in J}) = \lim_I \colim_J D_j^{C_i},
\]

where the limits and colimits are computed in the category of groupoids.

3.28. \textbf{Proposition.} We have an isomorphism of functors of \(C \in \hat{G}, \ D \in G\) and \(E \in \hat{G} : \)

\[
\hat{G}(C \times \hat{D}, E) \cong \hat{G}(C, E^D)
\]

Likewise, there is a natural isomorphism

\[
\hat{G}(C \times \hat{D}, E) \cong G(D, \text{map}(C, E))
\]

\textbf{Proof.} We prove the first isomorphism, the second is similar. Both sides preserve limits in the \(E\) variable and send colimits in the \(D\) variable to limits, hence, we can assume that \(E\) is in \(fG\) and that \(D\) is in \(G_f\). Let us write \(C = \{C_i\}_{i \in I}\), then we have

\[
\hat{G}(C, E^D) \cong \lim_I \left( \colim_J G(C_i \times D, E) \right)
\cong \lim_I \hat{G}(C_i \times \hat{D}, E)
\cong \colim_I \hat{G}(\hat{C} \times \hat{D}, E)
\]

where the last equality follows from proposition 3.23. Since \(E\) is in \(fG\), it is cosmall in \(\hat{G} = \text{Pro}(fG)\), thus, we have

\[
\hat{G}(C, E^D) \cong \hat{G}(\lim_I C_i \times \hat{D}, E) \cong \hat{G}(C \times \hat{D}, E)
\]

\(\square\)

Now, we can prove the following.

3.29. \textbf{Proposition.} The pairing

\[
\hat{G} \times G \to \hat{G}
\]

sending \((A, C)\) to \(A \times C\) makes \(\hat{G}\) into a symmetric monoidal model category

\textbf{Proof.} We have already seen that this functor is a left adjoint in both variables. It remains to prove that it has the pushout-product property. Recall from proposition 3.14 that a map is a cofibration in \(\hat{G}\) if and only if it is injective on objects.

(1) Let \(A \to B\) be a cofibration in \(\hat{G}\) and \(C \to D\) be a cofibration in \(G\), then the map

\[
A \times D \cup^A C \times B \to A \times B
\]

is injective on object. The proof is easy one we have observed that the functor that assigns to a groupoid or profinite groupoid its set of objects is colimit preserving.

(2) If \(C \to D\) is a weak equivalence in \(G\) and \(A\) is any object in \(\hat{G}\), then \(A \times \hat{C} \to A \times \hat{D}\) is a weak equivalence in \(\hat{G}\). Indeed, by proposition 3.10, we can assume that \(A\) is in \(fG\). By proposition 3.26, we are thus reduced to proving that

\[
\pi \hat{G}(\hat{D} \times A, K) \to \pi \hat{G}(\hat{C} \times A, K)
\]

is an isomorphism for all \(K \in fG\). By adjunction, we have an isomorphism \(\pi \hat{G}(\hat{C} \times A, K) \cong \pi \hat{G}(C, K^A)\) and similarly for the other side. Since \(K^A\) is a finite groupoid, we are done.
(3) Similarly, if \(A \to B\) is a weak equivalence in \(\hat{G}\) and \(C\) is a small groupoid (i.e. an object of \(G_I\)), then the map \(A \times \hat{C} \to B \times \hat{C}\) is a weak equivalence. Indeed, by adjunction, we are reduced to proving that

\[
\pi \hat{G}(B, \text{map}(C, K)) \to \pi \hat{G}(A, \text{map}(C, K))
\]

is an isomorphism for all \(K\). But this follows from the fact that \(\text{map}(C, K)\) is finite.

(4) Now, let \(A \to B\) be a trivial cofibration and \(C \to D\) be a cofibration, then the map

(3.1)

\[
A \times \hat{D} \sqcup A \times \hat{C} \to B \times \hat{C} \to B \times \hat{D}
\]

is a cofibration by (1). Moreover, the map \(A \times \hat{C} \to A \times \hat{D}\) is a cofibration by (1) and the map \(A \times \hat{C} \to B \times \hat{C}\) is a weak equivalence by (2). Thus, since \(G\) is left proper, the map 3.1 is a weak equivalence if and only if \(A \times \hat{D} \to B \times \hat{D}\) is a weak equivalence but this follows from (2).

The other case is dealt with similarly using (3) instead of (2) and observing that we can assume that \(C\) and \(D\) are small groupoids (for instance because the generating trivial cofibrations of \(G\) can be chosen with small source and target). \(\square\)

By adjunction, the functors \((C, E) \mapsto \text{map}(C, E)\) and \((D, E) \mapsto E^D\) are also Quillen bifunctors. Since the functor \(B : G \to S\) is a right Quillen functor, this implies that \((C, E) \mapsto B \text{map}(C, E)\) is a Quillen bifunctor. Hence it makes \(\hat{G}\) into a simplicial model category. We denote by \(\text{Map}_G(\_, \_\_\_\_)\) the functor \(B \text{map}(-, \_\_\_)\). Unwinding the definition, we see that \(\text{Map}_G(C, D)\) is the simplicial set whose \(k\)-simplices are \(\hat{G}(C \times I[k], D) \cong \hat{G}(C, D^{I[k]}).\)

Using the simplicialness of \(\hat{G}\), we can extend the criterion of proposition 3.26.

3.30. Proposition. A map \(u : A \to B\) is a weak equivalence in \(\hat{G}\) if and only if for any finite groupoid \(C\), the induced map

\[
\text{Map}_G(B, C) \to \text{Map}_G(A, C)
\]

is a weak equivalence.

Proof. If the induced map

\[
\text{Map}_G(B, C) \to \text{Map}_G(A, C)
\]

is a weak equivalence for all \(C\) in \(fG\), taking \(\pi_0\) and applying proposition 3.26, we find that \(u\) is a weak equivalence. Conversely, notice that the finite groupoids are fibrant in \(\hat{G}\). Indeed, \(* \hat{G}\) for \(G\) a finite group and \(\text{Codisc}(S)\) for \(S\) a finite set are fibrant by definition. Moreover, using the same trick as in the proof of proposition 3.26, we find that if \(U\) and \(V\) are fibrant, then \(U \sqcup V\) is a retract of \(U \times V \times \{0, 1\}\) and hence is fibrant. Since \(G\) is a simplicial model category and \(u\) is a weak equivalence between cofibrant objects, the map

\[
\text{Map}_G(B, C) \to \text{Map}_G(A, C)
\]

is a weak equivalence. \(\square\)

Barnea-Schlank model structure. Given category \(C\) with a subcategory \(wC\) of weak equivalences containing all the objects, one can define \(Lw^\infty(wC)\) to be the smallest class of arrows in \(\text{Pro}(C)\) that is stable under isomorphisms in the arrow category of \(\text{Pro}(C)\) and contains the natural transformations that are levelwise weak equivalences.

3.31. Definition. A weak fibration category is a triple \((C, wC, fC)\) of a small category with two subcategories containing all the objects such that :

- \(C\) has all finite limits.
- The maps in \(wC\) have the two-out-of-three property.
• The maps in $fC$ and $fC \cap wC$ are stable under base change.
• Any map has a factorization of the form $fC \circ wC$.

3.32. **Theorem** (Barnea-Schlank [BS11]). Let $C$ be a weak fibration category, then if $Lw^\otimes(wC)$ satisfies the two-out-of-three property, there is a model structure on $\text{Pro}(C)$ in which the weak equivalences are the maps of $Lw^\otimes(wC)$, the cofibrations are the map with the left lifting property against $fC$ and the trivial cofibrations are the map with the left lifting property against $fC \cap wC$.

Note that the condition that $Lw^\otimes(wC)$ has the two-out-of-three property is usually hard to check. Following Barnea Schlank, we call a weak fibration category satisfying this property a pro-admissible weak fibration category. There is a criterion on $C$ that insures that $C$ is pro-admissible.

3.33. **Definition.** Let $(C, wC)$ be a relative category. We say that a map $u : X \to Y$ is left proper if any base change of a weak equivalence $X \to Z$ along $u$ exists and is a weak equivalence. We say that $u$ is right proper if any base change of a weak equivalence $Z \to Y$ along $u$ exists and is a weak equivalence.

3.34. **Theorem** (Barnea-Schlank). Let $(C, wC)$ be a relative category. Let us denote by $LP$ resp. $RP$ the class of left proper (resp. right proper) maps in $C$. Then $Lw^\otimes(wC)$ satisfies the two-out-of-three property if any map in $C$ has a factorization of the form $wC \circ LP$, $RP \circ wC$ and $RP \circ LP$.

**Proof.** See [BS14, Proposition 3.6]. Note that the authors require that $C$ has all finite colimits and limits. However, an inspection of the proof shows that only the pushouts of a weak equivalence along a left proper map and the pullbacks of a weak equivalence along a right proper map are needed.

The category $fG$ of finite groupoids is a small category with finite limits. We can declare a map to be a fibration (resp. weak equivalence) if it is one in the canonical model structure on $G$.

3.35. **Proposition.** The category $fG$ with this notion of fibration and weak equivalence is a pro-admissible weak fibration category.

**Proof.** The fact that $fG$ is a weak fibration category follows easily from the existence of the canonical model structure on $G$. The only non-trivial axiom is the factorization axiom. Let $f : C \to D$ a map in $fG$. Using the path object $C \mapsto C^I[1]$, we can factor $f$ as

$$C \to C \times_D D^I[1] \to D$$

The first map is a weak equivalence and the second map is a fibration because all objects are fibrant in $G$. Moreover, the groupoid $C \times_D D^I[1]$ belongs to $fG$. Thus, we have constructed a factorization of $f$ as a weak equivalence followed by a fibration. Note that the first map is injective on object so it is in fact a cofibration in $G$.

Now, we want to prove that the maps in $Lw^\otimes(w(fG))$ have the two-out-of-three property. We will use the criterion of theorem 3.34. Note that $G$ is a right proper model category. It follows that any map in $fG$ which is a fibration in $G$ is right proper. Similarly, if $f : C \to D$ is injective on objects and $u : C \to C'$ is a weak equivalence, the pushout $C' \sqcup^C D$ is in $fG$, this implies that the maps that are injective on objects are left proper. Hence the previous paragraph gives us a factorization of $f$ of the form $RP \circ LP$ and $RP \circ w(fG)$. It only remains to construct a factorization of $f$ the form $w(fG) \circ LP$. This can be done by the following mapping cylinder construction

$$C \to (C \times I[1]) \cup^C D \to D$$

The first map is left proper since it is injective on objects and the second map is a weak equivalence.

It follows that there is a model structure $\hat{G}^{BS}$ on $\hat{G}$ in which the weak equivalences are the maps in $Lw^\otimes(w(fG))$, the cofibrations are the maps with the left lifting properties against the maps in $fG$.
that are fully faithful and surjective on objects and the trivial cofibrations are the maps with the left lifting property against the maps in \( f\mathcal{G} \) that are isofibrations.

The category \( f\mathcal{G} \) is cotensored over compact groupoids \( (\mathcal{G}_f)^\text{op} \times f\mathcal{G} \to f\mathcal{G} \) by restricting the inner \text{Hom} in groupoids: \( (\mathcal{C}, \mathcal{D}) \mapsto D^\mathcal{C} \). This cotensor satisfies the appropriate version of the axiom SM7. This implies by [Bar15] that \( \hat{\mathcal{G}}^{BS} \) is a \( \mathcal{G} \)-enriched model category. Applying \( B \) we see that the mapping space \( \text{Map}_\mathcal{G} \) gives \( \hat{\mathcal{G}}^{BS} \) the structure of a simplicial model category.

**Equality of the two model structures.** We now want to prove that \( \hat{\mathcal{G}}^{BS} \) and \( \hat{\mathcal{G}} \) are in fact the same model category. Our first task is to prove that they have the same cofibrations.

3.36. **Lemma.** Let \( u : S \to T \) be a surjective maps of finite sets. Then, there exists a set \( E \) and a retract diagram

\[
\begin{array}{ccc}
S & \xrightarrow{i} & E \times T & \xrightarrow{f} & S \\
\downarrow{u} & & \downarrow{\pi_2} & & \downarrow{u} \\
T & \xrightarrow{id} & T & \xrightarrow{id} & T
\end{array}
\]

**Proof.** Let \( S_t \) denote the fiber of \( S \) over \( t \). We take \( E \) to be a finite set of bigger cardinality than any of the sets \( S_t \), we pick for each \( t \) an injection \( i_t : S_t \to E \) and a map \( f_t : E \to S_t \) so that \( f_t \circ i_t = \text{id}_{S_t} \). Then we define \( i := \sqcup i_t : S \cong \sqcup S_t \to E \times T \cong \sqcup E \) and \( f_t \) in a similar way.

3.37. **Proposition.** The closure of \( Q \) under retracts, base change and composition contains the maps of \( f\mathcal{G} \) that are trivial fibrations in \( \mathcal{G} \).

**Proof.** Let us denote by \( E \) the closure of \( Q \) under retracts, base change and composition. Let \( f : \mathcal{C} \to \mathcal{D} \) be a trivial fibration in \( \mathcal{G} \) between objects of \( f\mathcal{G} \). Then \( f \) is fully faithful and surjective on objects. Let us assume that \( \mathcal{D} \) is connected. In that case, \( f \) can be identified non-canonically with the map

\[
\mathcal{G}[S] \to \mathcal{G}[T]
\]

induced by a surjective map \( u : S \to T \). According to the previous lemma, \( u \) fits in a retract diagram

\[
\begin{array}{ccc}
S & \xrightarrow{i} & E \times T & \xrightarrow{f} & S \\
\downarrow{u} & & \downarrow{\pi_2} & & \downarrow{u} \\
T & \xrightarrow{id} & T & \xrightarrow{id} & T
\end{array}
\]

It follows that the map \( \text{Codisc}(S) \to \text{Codisc}(T) \) induced by \( u \) is a retract of the map \( \text{Codisc}(E \times T) \to \text{Codisc}(T) \) induced by \( \pi_2 \). The functor \( \text{Codisc} \) preserves products, thus, this last map is the product of the map \( \text{Codisc}(S) \to * \) with \( \text{Codisc}(T) \). In particular, it is a base change of a map of \( Q' \) hence is in \( E \) by lemma 3.13. This implies that \( \text{Codisc}(u) \) is in \( E \) and that \( f \) is in \( E \).

Now, let \( f : \mathcal{C} \to \mathcal{D} \) and \( f' : \mathcal{C}' \to \mathcal{D}' \) be two maps in \( E \) with non-empty target, we will show that \( f \cup f' \) is also in \( E \). Since any finite groupoid splits as a finite disjoint union of connected groupoid, this will conclude the proof. We pick an object \( c \) of \( \mathcal{C} \) and \( c' \) of \( \mathcal{C}' \), we call \( d \) and \( d' \) their image in \( \mathcal{D} \) and \( \mathcal{D}' \). Then we have a retract diagram

\[
\begin{array}{ccc}
C \cup C' & \xrightarrow{i} & C \times C' \times \{0, 1\} & \xrightarrow{p} & C \cup C' \\
D \cup D' & \xrightarrow{i'} & D \times D' \times \{0, 1\} & \xrightarrow{p'} & D \cup D'
\end{array}
\]
in which the vertical maps are induced by \( f \) and \( f' \), the map \( i \) is the map that sends \( x \in C \) to \((x, c', 0)\) and \( y \in C'\) to \((c, y, 1)\), the map \( p \) is the map that sends \((x, y, 0)\) to \(x\) and \((x, y, 1)\) to \(y\) and the maps \( i' \) and \( p' \) are defined analogously. According to this retract diagram, it suffices to prove that \( f \times f' \times \{0, 1\} \) is in \( E \). The map \( f \times f' \times \{0, 1\} \) is base change of \( f \times f' \), thus it suffices to show that \( f \times f' \) is in \( E \). But, we have

\[
f \times f' = (f \times D') \circ (C \times f')
\]

which implies that \( f \times f' \) is in \( E \). \( \square \)

By lemma 3.21 the maps in \( Q \) are trivial fibrations in \( \hat{G}^{BS} \). Therefore, the previous proposition tells us that \( \hat{G}^{BS} \) and \( \hat{G} \) have the same cofibrations. In order to prove that \( \hat{G} \) and \( \hat{G}^{BS} \) are the same model category, it suffices to prove that they have the same weak equivalences.

3.38. Proposition. The weak equivalences of \( \hat{G}^{BS} \) are exactly the weak equivalences of \( \hat{G} \).

Proof. We already know from proposition 3.10 that the weak equivalences of \( \hat{G}^{BS} \) are weak equivalences in \( \hat{G} \). Conversely, let \( u : A \to B \) be a weak equivalence in \( \hat{G} \).

Let \( C \) be a fibrant object of \( \hat{G}^{BS} \). Since \( \hat{G}^{BS} \) is cofibrantly generated, \( C \) is a retract of \( C' \) with \( C' = \lim_{i \in C''} C'_i \) a cocell complex with respect to the canonical fibrations in \( fG \). If \( \alpha \) is a finite ordinal, this immediately implies that \( C' \) is a finite groupoid and thus, by proposition 3.30, this implies that the map

\[
\Map_{\hat{G}}(B, C') \to \Map_{\hat{G}}(A, C')
\]

is a weak equivalence. By proposition 3.10, we see that cofiltered limits in \( \hat{G} \) are homotopy limits. Thus, if \( \alpha \) is infinite, we see that:

\[
\Map_{\hat{G}}(B, C') \simeq \holim_{i \in C''} (B, C'_i)
\]

and similarly for \( \Map_{\hat{G}}(A, C') \). This implies that the map induced by \( u \):

\[
\Map_{\hat{G}}(B, C') \to \Map_{\hat{G}}(A, C')
\]

is a weak equivalence. Since \( C \) is a retract of \( C' \), the map

\[
\Map_{\hat{G}}(B, C) \to \Map_{\hat{G}}(A, C)
\]

is also a weak equivalence. This implies by Yoneda lemma in \( \Ho(\hat{G}^{BS}) \) that \( u \) is an isomorphism in \( \Ho(\hat{G}^{BS}) \) \( \square \)

From this proposition, we can gives a conceptual interpretation of the \( \infty \)-category underlying \( \hat{G} \):

3.39. Theorem. The underlying \( \infty \)-category of \( \hat{G} \) is equivalent to the pro-category of the \( \infty \)-category of 1-truncated \( \pi \)-finite spaces.

Proof. For \( C \) a relative category, we denote by \( C_{\infty} \) its underlying \( \infty \)-category. Using the main result of [BHH15], we get that \( \hat{G}_{\infty} = \hat{G}^{BS}_{\infty} \simeq \Pro(fG_{\infty}) \). Thus, it suffices to show that \( fG_{\infty} \) is a model for the \( \infty \)-category of 1-truncated \( \pi \)-finite spaces. The classifying space functor \( fG \to S \) is simplicial and fully faithful, moreover it preserves weak equivalences and fibrant objects. Thus, it induces a fully faithful functor \( B : fG_{\infty} \to S_{\infty} \). It suffices to check that any 1-truncated \( \pi \)-finite space is weakly equivalent to one of the form \( BC \) with \( C \in fG \). Since \( B \) commutes with finite coproducts, we can restrict to connected spaces. If \( X \) is a 1-truncated connected \( \pi \)-finite simplicial set. Then \( X \simeq B\pi_1(X, x) \) for any base point \( x \) of \( X \). \( \square \)

This also has the following corollary.
3.40. Proposition. Any profinite groupoid of the form $G[S]$ with $G$ a profinite group and $S$ a finite set is fibrant.

Proof. Since $\text{Codisc}(S) \rightarrow \ast$ is in $Q'$, the object $\text{Codisc}(S)$ is fibrant in $\hat{G}$. Hence, we are reduced to proving that $\ast \parallel G$ is fibrant in $\hat{G}$. Let $\mathcal{N}(G)$ be the poset of open normal subgroups of $G$ of finite index. We have an isomorphism

$$\ast \parallel G \cong \lim_{U \in \mathcal{N}(G)} \ast \parallel (G/U)$$

For any $U \in \mathcal{N}(G)$, the map

$$\ast \parallel (G/U) \rightarrow \lim_{V \supseteq U \in \mathcal{N}(G)} \ast \parallel (G/V)$$

is a fibration in $fG$. Thus $\ast \parallel G$ is fibrant in $\hat{G}$BS as the limit of a Reedy fibrant diagram $\mathcal{N}(G) \rightarrow \hat{G}$BS.

□

4. Profinite spaces

We recall a few facts about the homotopy theory on profinite spaces. This theory was originally developed by Morel (see [Mor96]) in the pro-$p$ case and then continued by Quick (see [Qui08]) in the profinite case.

Quick’s model structure. We denote by $\text{Set}$ the category of sets and by $F$ the full subcategory on finite sets. We denote by $\hat{\text{Set}}$ the category $\text{Pro}(F)$.

4.1. Proposition. The category $\hat{\text{Set}}$ is copresentable.

Proof. Since $\text{Set}$ has finite limits we can apply proposition 2.3. □

If $S$ is a set, the functor $F \rightarrow \text{Set}$ sending $U$ to $\text{Set}(S, U)$ preserves finite limits and therefore is represented by an object $\hat{S}$ in $\text{Pro}(\text{Set})$ according to remark 2.5. There is an adjunction

$$\hat{(-)} : \text{Set} \rightleftarrows \hat{\text{Set}} : | - |$$

where the right adjoint sends a profinite set to its limit computed in $\text{Set}$.

There is a more explicit description of $\hat{-}$. For $S$ a set, $\hat{S}$ is the pro-object $\{S/R\}_R$ where $R$ lives in the cofiltered poset of equivalences relations on $S$ whose set of equivalences classes is finite.

4.2. Definition. The category $\hat{S}$ of profinite spaces is the category of simplicial objects in $\hat{\text{Set}}$.

This category is also copresentable. There is an alternative definition of this category. We denote by $S_{\text{cofin}}$, the category of simplicial objects in finite sets that are $k$-coskeletal for some $k$. This category $S_{\text{cofin}}$ has all finite limits, thus the pro category $\text{Pro}(S_{\text{cofin}})$ is a copresentable category. There is an inclusion functor $S_{\text{cofin}} \rightarrow \hat{S}$ which preserves finite limits. This functor induces a limit preserving functor $\text{Pro}(S_{\text{cofin}}) \rightarrow \hat{S}$.

4.3. Proposition. The functor $\text{Pro}(S_{\text{cofin}}) \rightarrow \hat{S}$ is an equivalence of categories.

Proof. See [BHH15] □

4.4. Theorem (Quick). There is a fibrantly generated model structure on $\hat{S}$. The cofibrations are the monomorphisms and the weak equivalences are the maps which induce isomorphisms on $\pi_0$ as well as on non-abelian cohomology with coefficient in a finite group and on cohomology with coefficient in a finite abelian local coefficient system. Moreover, this model structure is simplicial and left proper.
Proof. See [Qui08, Theorem 2.1.2] with a correction in [Qui11, Theorem 2.3.]\(^1\). □

Profinite completion of spaces. There is a functor
\[ \widehat{(-)} : S = \text{Fun}(\Delta^{op}, \text{Set}) \to \hat{S} = \text{Fun}(\Delta^{op}, \text{Set}) \]
which is a left adjoint to the functor
\[ |-| : \hat{S} \to S \]
obtained by applying the functor \(|-| : \hat{\text{Set}} \to \text{Set}\) levelwise. Using the description of \(\hat{S}\) as \(\text{Pro}(S_{\text{cofin}})\) and remark 2.5, we can define \(\hat{X}\) as the functor \(S(X, -)\) which is clearly a functor \(S_{\text{cofin}} \to \text{Set}\) which preserves finite limits.

4.5. Theorem. The adjunction
\[ \widehat{(-)} : S \leftrightarrow \hat{S} : |-| \]
is a Quillen adjunction

Proof. See [Qui08, Proposition 2.28.]. □

4.6. Remark. Let \(S_\infty\) be the \(\infty\)-category of spaces and \(S^\pi_\infty\) be the full subcategory spanned by \(\pi\)-finite spaces (i.e. spaces \(X\) with \(\pi_0(X)\) finite and \(\pi_i(X, x)\) finite for each \(x\) and \(\pi_i(X, x) = 0\) for \(i\) big enough. In [BHH15], we prove that the underlying \(\infty\)-category of Quick’s model structure is equivalent to \(\text{Pro}(S^\pi_\infty)\) the (\(\infty\)-categorical) pro-category of \(S^\pi_\infty\) and that the profinite completion functor \(S \to \hat{S}\) is a model for the functor \(S_\infty \to \text{Pro}(S^\pi_\infty)\) sending \(X\) to \(\text{Map}(X, -)\) seen as a limit preserving functor \(S^\pi_\infty \to S_\infty\).

Profinite classifying space functor. There is an adjunction
\[ \pi : S \leftrightarrow G : B \]
The functor \(B\) is the nerve functor \(\text{Cat} \to S\) restricted to groupoids. The functor \(\pi\) sends a simplicial set \(X\) to a groupoid \(\pi(X)\). The groupoid \(\pi(X)\) is the groupoid completion of a category \(\pi'(X)\). The category \(\pi'(X)\) is the free category on the graph \(X_1 \rightrightarrows X_0\) modulo the relation \(u \circ v = w\) if there is a 2-simplex \(y\) of \(X\) with \(d_0(y) = u, d_1(y) = w\) and \(d_2(y) = v\).

This adjunction restricts to an adjunction
\[ \pi : S_{\text{cofin}} \leftrightarrow fG : B \]
Passing to the pro-categories on both sides, we get an adjunction
\[ (4.1) \quad \pi : \text{Pro}(S_{\text{cofin}}) \simeq \hat{S} \leftrightarrow \hat{G} : B \]
The functor \(B\) preserves generating fibrations and generating trivial fibrations. Therefore it is a Quillen right functor. Hence we have a diagram of right Quillen functors which commutes up to a canonical isomorphism:

\[ \begin{array}{ccc}
\hat{G} & \xrightarrow{|-|} & G \\
B \downarrow & & \downarrow B \\
\hat{S} & \xrightarrow{|-|} & S
\end{array} \]

\(^{1}\text{Note that there is still a small mistake in the generating fibrations in [Qui11]. An updated version of this paper can be found on G. Quick’s webpage http://www.math.ntnu.no/~gereonq/. In this version the relevant result is theorem 2.10.}\)
4.7. **Proposition.** Let $C$ be a fibrant profinite groupoid, then the counit map
\[ \pi \mathcal{B}C \to C \]
is a weak equivalence in $\check{G}$

**Proof.** It suffices to prove that for any $D$ fibrant in $\check{G}$, the map
\[ \text{Map}_{\check{G}}(C, D) \to \text{Map}_{\check{S}}(\pi \mathcal{B}C, D) \]
is a weak equivalence. By theorem 1.3, it suffices to prove that the map
\[ \text{Map}_{\check{G}}(C, D) \to \text{Map}_{\check{S}}(\mathcal{B}C, BD) \]
is a weak equivalence. Since $\check{G}$ and $\check{S}$ are simplicial and any object is cofibrant in both model categories, it suffices to show that
\[ \text{Map}_{\check{G}}(C, D) \to \text{Map}_{\check{S}}(\mathcal{B}C, BD) \]
is a weak equivalence. We claim that it is in fact an isomorphism. Indeed, it suffices to show that it is an isomorphism in each degree. We have $BD\Delta[k] \cong B(D^I[k])$. Thus it suffices to prove that $B$ is fully faithful as a functor $\check{G} \to \check{S}$ which is obvious. □

**Good groupoids à la Serre.** For $C$ a groupoid, the unit map $C \to |\hat{C}|$ induces a map $\mathcal{B}C \to B(|\hat{C}| \cong |B\hat{C}|$. This last map is adjoint to a map $\mathcal{B}C \to B\hat{C}$.

This map fails to be a weak equivalence in $\check{S}$ in general, however, it is in some cases. Let us recall, the definition of a good group due to Serre.

4.8. **Definition.** Let $G$ be a discrete group and $\hat{G}$ be its profinite completion, we say that $G$ is **good** if for any finite abelian group with a $\hat{G}$-action $M$, the restriction map
\[ H^*(\hat{G}, M) \to H^*(G, M) \]
is an isomorphism. If $C$ is a groupoid with a finite set of objects, we say that $C$ is good if each of the automorphisms of each object of $C$ is a good group.

4.9. **Proposition.** Let $C$ be a good groupoid. Then the map
\[ \mathcal{B}C \to B\hat{C} \]
is a weak equivalence in $\check{S}$.

**Proof.** We can write $C$ as a disjoint union of groupoids of the form $G[S]$ where $G$ is good and $S$ is finite. Since completion commutes with colimits both in spaces and groupoids and $B$ preserve coproducts of groupoids, we are reduced to proving that for any good group $G$ and finite set $S$, the map
\[ B\mathcal{G}[S] \to B\hat{G}[S] \]
is an equivalence in $\check{S}$. We have an obvious projection $G[S] \to G$ which is a weak equivalence in $\mathcal{G}$. We have a commutative diagram
\[
\begin{array}{ccc}
B\hat{G}[S] & \longrightarrow & B\mathcal{G}[S] \\
\downarrow & & \downarrow \\
B\hat{G} & \longrightarrow & B\hat{G}
\end{array}
\]
The two vertical maps are weak equivalences in $\check{S}$. The bottom map is a weak equivalence according to [Qui12, Proposition 3.6.]. This implies that the top map is an equivalence. □

We will need the following fact about good groups
4.10. **Proposition.** Let 
\[ 1 \to N \to G \to H \to 1 \]
be an exact sequence of groups in which \( N \) is finitely presented and \( H \) is good, then

1. There is a short exact sequence of topological groups 
\[ 1 \to \hat{N} \to \hat{G} \to \hat{H} \to 1 \]
2. If moreover \( N \) is good, then \( G \) is good.

**Proof.** This proposition is an exercise in [Ser94, p. 13]. The first claim is proved in [Nak94, Proposition 1.2.4]. The second claim can be found in [Nak94, Proposition 1.2.5]. □

4.11. **Corollary.** The pure braid groups \( K_n \) are good.

**Proof.** This is also an exercise in [Ser94, p. 14]. This follows from an induction applying the previous proposition to the short exact sequence 
\[ 1 \to F_n \to K_{n+1} \to K_n \to 1 \]
and using the fact that the free groups are good. The details are worked out in [Col11, Proposition 2.1.6]. □

4.12. **Corollary.** Let \( C \) and \( D \) be two good groupoids and assume that any automorphism group of \( C \) is finitely presented, then \( C \times D \) is a good groupoid.

**Proof.** We can reduce to the case of groups as in the proof of proposition 4.9 and then it suffices to apply proposition 4.10. □

5. **Operads in groupoids**

The operad of parenthesized braids. We denote by \( B_n \) the braid group on \( n \)-strands and by \( K_n \) the pure braid group on \( n \) strands, i.e. the kernel of the group homomorphism 
\[ B_n \to \Sigma_n \]
sending a braid to its underlying permutation.

5.1. **Construction.** We define an operad \( PaB \) in groupoids.

The set of objects of the groupoid \( PaB(n) \) is the set of pairs \( (\sigma, p) \) where \( \sigma \) is a bijection from \( \{1, \ldots, n\} \) to itself and \( p \) is the data of a parenthesization of \( \sigma(1)\sigma(2)\ldots\sigma(n) \).

For instance \((13)(42)\) and \(3(1(24))\) are two objects of \( PaB(4) \).

The set of morphisms between two objects \( (\sigma, p) \) and \( (\tau, q) \) of \( PaB(n) \) is the set of braids in \( B_n \) whose image in \( \Sigma_n \) is the permutation \( \tau \circ \sigma^{-1} \). Composition is given by composition of braids.

Note in particular that \( PaB(0) \) is the terminal groupoid.

The group of automorphisms of any object of \( PaB(n) \) is the pure braid group \( K_n \). Moreover, since any two object are isomorphic in \( PaB(n) \), the groupoid \( PaB(n) \) is weakly equivalent to \( * \text{ // } K_n \).

The important fact about \( PaB \) is that it is a groupoid model for \( \mathcal{E}_2 \).

5.2. **Proposition.** Let \( B : G \to S \) be the classifying space functor. Then the operad \( BPaB \) is weakly equivalent to \( \mathcal{E}_2 \).

**Proof.** Follows from Fiedorowicz recognition principle. This argument is made explicit in [Tam03, Section 3.2.]. □
5.3. **Remark.** The operad $PaB$ is not only a convenient model of $E_2$. One of the reasons for its importance in mathematics is that it is exactly the operad which encodes the structure of a braided monoidal category with a strict unit. An explanation of the relationship between $PaB$ and braided monoidal categories can be found in [Fre15a, 6.2.7].

**Cofibrant objects in $OpG$.**

5.4. **Theorem.** The category of operads in $G$ has a model structure in which the weak equivalences and fibrations are the maps that are levelwise weak equivalences and fibrations.

**Proof.** The model category $G$ is cartesian closed, cofibrantly generated and all objects in it are cofibrant and fibrant, therefore the hypothesis of [BM03, Theorem 3.2] are satisfied. □

Let $Ob : G \to Set$ be the functor sending a groupoid to its set of objects. We have already seen that $Ob$ has a left adjoint that we denote Disc and a right adjoint that we denote Codisc.

The functor $Ob$, Disc and Codisc all preserve products and we use the same notation for the functors $OpG \to Op$ and $Op \to OpG$ that they induce. We have two adjunctions

$$Disc : Op \rightleftarrows OpG : Ob$$

$$Ob : OpG \rightleftarrows Op : Codisc$$

5.5. **Proposition.** The cofibrations in $OpG$ are exactly the maps $u : A \to B$, such that $Ob(u)$ has the left lifting property against the maps which are levelwise surjective.

**Proof.** Let $C$ be the class of maps $u : A \to B$, such that $Ob(u)$ has the left lifting property against the maps which are levelwise surjective. The functor $Ob$ has a right adjoint. This implies that the class $C$ is stable under transfinite compositions, pushouts and retracts. Moreover, the generating cofibrations are in $C$, this implies that $C$ contains the cofibrations of $OpG$.

Conversely, let $u : A \to B$ be a map of $C$. Let $p : O \to P$ be a trivial fibration in $OpG$. We have the following diagram

$$\begin{array}{ccc}
Disc Ob A & \xrightarrow{c} & A \\
\downarrow{a} & & \downarrow{f} \\
Disc Ob B & \xrightarrow{d} & B \\
\end{array}$$

$$\begin{array}{ccc}
& & O \\
p & & \downarrow{g} \\
& & P \\
\end{array}$$

where $c$ and $d$ are the counits of the adjunction $(Disc, Ob)$. Since $Ob(p)$ is surjective, and $u$ is in $C$, then there is a map $k : Disc Ob B \to O$ such that $pk = gd$. Now we construct a map $l : B \to O$.

Since the map $d$ is levelwise bijective on object, we can define declare $l$ of an object of $B(n)$ to be $k$ of the same object of $Disc Ob B(n)$.

The map $p$ is levelwise surjective on objects and fully faithful. Thus for any map $\alpha$ in $P(n)$ and any choice of lift of its source and target in $O(n)$, there is a unique map in $O(n)$ which lifts $\alpha$ and has the chosen source and target.

Hence, we can define $l$ of an arrow of $\alpha$ of $B(n)$ to be the unique map lifting $g(\alpha)$ whose source is $l$ of the source of $\alpha$ and target is $l$ of the target of $\alpha$.

This defines $l$ as a map of sequences of groupoids. The map $Ob(l) : Ob B \to Ob O$ is a map of operads in sets by construction. To check that $l$ is actually a map of operads, it suffices to check that for any arrow $\alpha$ in $B(n)$ and $\beta$ in $B(m)$, we have the identity

$$l(\alpha \circ_i \beta) = l(\alpha) \circ_i l(\beta)$$
The two sides of this equation are arrows in $O(m + n - 1)$ which lift $g(\alpha \circ_i \beta)$. Moreover both sides of the equation have same source and target. Therefore, by our previous observation, both sides are actually equal. 

5.6. Corollary. Let $A$ be an operad in $\text{OpG}$ such that $\text{Ob} A$ is a free operad, then $A$ is cofibrant.

5.7. Corollary. The operad $\mathcal{P}aB$ is cofibrant in $\text{OpG}$

Proof. Indeed, $\text{Ob} \mathcal{P}aB$ is the operad $F(2)$ where $F$ is defined in the appendix. 

6. The Grothendieck-Teichmüller group

Drinfel’d’s definition. Recall from proposition 3.23 that for groupoids with a finite set of objects, the profinite completion functor is symmetric monoidal. Thus there is an operad $\hat{\mathcal{P}}aB$ obtained by applying the profinite completion functor in each arity to the operad in groupoid $\mathcal{P}aB$.

Let us recall a notation. For $i \leq n - 1$, we denote by $\sigma_i$ the Artin generator of $B_n$. The group $B_n$ can then be defined as

$$B_n = \langle \sigma_1, \ldots, \sigma_{n-1} | \sigma_i \sigma_{i+1} \sigma_{i+1} = \sigma_{i+1} \sigma_i \sigma_{i+1}, \sigma_i \sigma_j = \sigma_j \sigma_i \text{ if } |i - j| \geq 2 \rangle$$

For $i < j$, we denote by $x_{ij}$ the element of $K_n$ defined by

$$x_{ij} = (\sigma_{j-1} \ldots \sigma_{i+1}) \sigma_i^2 (\sigma_{j-1} \ldots \sigma_{i+1})^{-1}$$

The $x_{ij}$ generate $K_n$.

6.1. Definition. We define the profinite Grothendieck-Teichmüller monoid $\hat{\text{GT}}$ to be the subset of elements $(\lambda, f)$ of $\hat{\mathbb{Z}} \times \hat{\mathbb{F}}_2$ satisfying the following equations:

1. $f(x, y)f(y, x) = 1$.
2. $f(z, x)z^m f(y, z)y^m f(x, y)x^m = 1$ for $xyz = 1$ and $m = (\lambda - 1)/2$.
3. In the profinite group $\hat{\mathbb{K}}_4$ we have the equation

$$f(x_{12}, x_{23}x_{42})f(x_{13}, x_{23}x_{34}) = f(x_{23}, x_{34})f(x_{12}x_{13}, x_{24}x_{34})f(x_{12}, x_{23})$$

There is a monoid structure on $\hat{\text{GT}}$ given by

$$(\lambda_1, f_1), (\lambda_2, f_2) = (\lambda_1 \lambda_2, f_1(f_2(x, y)x^{\lambda_2}f_2(x, y)^{-1}, y^{\lambda_2})f_2(x, y))$$

The easiest way to understand this monoid structure is to consider the injective map

$$\hat{\text{GT}} \to \text{End}(\hat{\mathbb{F}}_2)$$

which sends $(\lambda, f)$ to the unique continuous group homomorphism

$$\hat{\mathbb{F}}_2 \to \hat{\mathbb{F}}_2$$

sending $x$ to $x^\lambda$ and $y$ to $f^{-1}y^\lambda f$. The monoid structure on $\hat{\text{GT}}$ is then given by composition of endomorphisms.

6.2. Theorem (Drinfel’d). The monoid $\hat{\text{GT}}$ is the monoid of endomorphisms of $\hat{\mathcal{P}}aB$ which induce the identity on $\text{Ob} \hat{\mathcal{P}}aB$.

Proof. See [Dri90, Section 4].

We denote by $\text{GT}$ the group of units of $\hat{\text{GT}}$. The previous theorem has the following immediate corollary.
6.3. Corollary. The group $\hat{\text{GT}}$ is the group of automorphisms of $\hat{\mathbb{P}uB}$ which induce the identity on objects.

Since profinite completion preserves surjections of groups, the abelianization map $F_2 \to \mathbb{Z}^2$ induces a surjective map of topological groups $\hat{F}_2 \to \hat{\mathbb{Z}}^2$.

6.4. Proposition. If $(\lambda, f) \in \hat{\text{GT}}$, then $f$ maps to 0 in $\hat{\mathbb{Z}}^2$.

Proof. The image of $f$ in $\hat{\mathbb{Z}}^2$ is of the form $\mu x + \nu y$ with $\mu$ and $\nu$ two elements in $\hat{\mathbb{Z}}$. We want to prove that $\mu = \nu = 0$.

Recall that we have the generators $x_{ij}$ in $K_n$. The relations between the $x_{ij}$ are all in the commutator subgroup of $K_n$ as explained in [Dri90, Equation 6.4, 4.7, 4.8 and 4.9]. This implies that the abelianization of $K_n$ is the free abelian group on $x_{ij}$ $1 \leq i < j \leq n$. In particular, we have a surjective map $\hat{K}_4 \to \hat{\mathbb{Z}}^6$ where the 6 generators of the target are the images of $x_{12}$, $x_{13}$, $x_{14}$, $x_{23}$, $x_{24}$ and $x_{34}$. We thus get a surjective map $\hat{K}_4 \to \hat{\mathbb{Z}}^6$.

We map the third equation defining $\hat{\text{GT}}$ to $\hat{\mathbb{Z}}^6$ via the above map $\hat{K}_4 \to \hat{\mathbb{Z}}^6$. We get the following equation $\mu x_{12} + \nu x_{34} = 0$ in the group $\hat{\mathbb{Z}}^6$ which immediately implies that $\mu = \nu = 0$. □

The action on $\hat{K}_4$. We have the category $\hat{\text{Grp}}$ of profinite groups. We denote by $\hat{\text{Grp}}$ the category whose objects are profinite groups and whose morphisms are conjugacy classes of continuous group homomorphisms. The $\hat{\text{-}}$-prefix stands for “unbased” as these correspond to homotopy classes of morphisms between the classifying spaces seen as unbased spaces.

6.5. Lemma. Let $\hat{F}_2$ be the free profinite group on two generators $x$ and $y$. For any $\lambda \in \hat{\mathbb{Z}} - \{0\}$, the centralizer of $x^\lambda$ is the subgroup generated by $x$.

Proof. This is [Nak94, Lemma 2.1.2.]. □

6.6. Proposition. The composite

$$\hat{\text{GT}} \to \text{End}_{\hat{\text{Grp}}}(\hat{F}_2) \to \text{End}_{\hat{\text{Grp}}}(\hat{F}_2)$$

is injective.

Proof. Let $(\lambda, f)$ and $(\mu, g)$ be two elements of $\hat{\text{GT}}$ whose image in $\text{End}(\hat{F}_2)$ are conjugate by some element $h \in \hat{F}_2$.

We have the two equations

$$x^\lambda = h^{-1} x^\mu h$$

$$f^{-1} y^\lambda f = h^{-1} g^{-1} y^\mu g h$$

Passing the first equation to the abelianization of $\hat{F}_2$, we see that $\lambda = \mu$. This means that $h$ is in the centralizer of $x^\lambda$ which implies according to lemma 6.5 that $h = x^\nu$ for some $\nu$ in $\hat{\mathbb{Z}}$.

The second equation informs us that $f h^{-1} g^{-1}$ is in the centralizer of $y^\mu$ which according to lemma 6.5 implies that $f h^{-1} g^{-1} = y^\rho$ for some $\rho$ in $\hat{\mathbb{Z}}$.

The elements $f$ and $g$ are sent to zero by the map $h F_2 \to \hat{\mathbb{Z}}^2$ by proposition 6.4, thus we can evaluate the equation $f h^{-1} g^{-1} = y^\rho$ in $\hat{\mathbb{Z}}^2$ and we find that $\nu = \rho = 0$ which in turns implies that $f = g$. □

Let $B_3$ be the braid group on three strands. It has two generators $\sigma_1$ and $\sigma_2$ and one relation $\sigma_1 \sigma_2 \sigma_1 = \sigma_2 \sigma_1 \sigma_2$. There is a surjective map $B_3 \to \Sigma_3$.
sending $\sigma_1$ to the permutation (12) and $\sigma_2$ to (23).

We can apply profinite completion to this map and we get another surjective map

$$\widehat{B}_3 \to \Sigma_3$$

The kernel of the map $B_3 \to \Sigma_3$ is $K_3$, the pure braid group on three strands. The center of $K_3$ is an infinite cyclic group generated by $(\sigma_1 \sigma_2)^3$. The elements $\sigma_1^2$ and $\sigma_2^2$ generate a free subgroup on 2-generators and in fact there is an isomorphism

$$K_3 \cong \mathbb{Z} \times F_2$$

The kernel of the map $\widehat{B}_3 \to \Sigma_3$ is $\overline{K}_3$, the profinite completion of the pure braid group. This follows from the first claim of proposition 4.10 together with the observation that finite groups are good and that $K_3 = F_2 \times \mathbb{Z}$ is finitely presented. Using proposition 4.10 we also find an isomorphism

$$\overline{K}_3 \cong F_2 \times \widehat{\mathbb{Z}}$$

There is an action of $\overline{\text{GT}}$ on $\widehat{B}_3$. The element $(\lambda, f)$ sends $\sigma_1$ to $\sigma_1^\lambda$ and $\sigma_2$ to $f(\sigma_2^\lambda, \sigma_2^\lambda) f(\sigma_2^\lambda, \sigma_2^\lambda)$. It is easy to see that any endomorphism of $\widehat{B}_3$ of this form commutes with the surjection to $\Sigma_3$. Therefore, the action of $\overline{\text{GT}}$ on $\widehat{B}_3$ restricts to an action on $\overline{K}_3$. Using the fact that $f(x, y) = f(y, x)^{-1}$ we see that this action of $\overline{\text{GT}}$ on $\overline{K}_3$ restricts further to the standard action on $\widehat{F}_2$.

6.7. Proposition. The action of $\overline{\text{GT}}$ on $\overline{K}_3$ induces an injection

$$\overline{\text{GT}} \to \text{End}_{u\text{Grp}}(\overline{K}_3)$$

Proof. Let us denote by $\text{End}_{\text{Grp}}(\overline{K}_3|\widehat{F}_2)$ (resp. $\text{End}_{u\text{Grp}}(\overline{K}_3|\widehat{F}_2)$) the set of endomorphisms of $\overline{K}_3$ which preserve $\widehat{F}_2 \subset \overline{K}_3$ (resp. the quotient of this set by the action of $\overline{K}_3$ by conjugation), we have a commutative diagram where the horizontal maps are given by restriction to $\widehat{F}_2$.

\[
\begin{array}{ccc}
\overline{\text{GT}} & \rightarrow & \text{End}_{\text{Grp}}(\overline{K}_3|\widehat{F}_2) \\
& & \downarrow \\
& & \text{End}_{u\text{Grp}}(\overline{K}_3|\widehat{F}_2)
\end{array}
\]

We have proved in proposition 6.6 that $\overline{\text{GT}} \to \text{End}_{u\text{Grp}}(\overline{K}_3|\widehat{F}_2)$ is injective. Thus, the map $\overline{\text{GT}} \to \text{End}_{u\text{Grp}}(\overline{K}_3|\widehat{F}_2)$ must be injective as well. On the other hand, the injective map

$$\text{End}_{\text{Grp}}(\overline{K}_3|\widehat{F}_2) \rightarrow \text{End}_{u\text{Grp}}(\overline{K}_3)$$

induces an injective map

$$\text{End}_{u\text{Grp}}(\overline{K}_3|\widehat{F}_2) \rightarrow \text{End}_{u\text{Grp}}(\overline{K}_3)$$

which concludes the proof.

A homotopical definition of $\overline{\text{GT}}$. We want to give an alternative definition of $\overline{\text{GT}}$ with a more homotopical flavor. Recall that for two profinite groupoids $C$ and $D$, a homotopy between $f$ and $g$ two maps from $C$ to $D$ is a map $h : C \to D^{[1][1]}$ whose evaluation at both objects of $[1][1]$ are $f$ and $g$. We denote by $\pi \widehat{\text{G}}$ the category whose objects are profinite groupoids and whose morphisms are homotopy classes of maps.

For an operad in profinite groupoid $\mathcal{O}$, we can define $\mathcal{O}^{[1][1]}$ by applying the product preserving functor $(-)^{[1][1]}$ levelwise.
6.8. Theorem. The composite
\[ \hat{G} \hat{T} \to \text{End}_{\hat{\text{Op}} \hat{G}}(\hat{\mathcal{P}aB}) \to \text{End}_{\pi \hat{\text{Op}} \hat{G}}(\hat{\mathcal{P}aB}) \]
is an isomorphism.

Proof. Let us first prove the surjectivity. Since \( \hat{G} \hat{T} \) is the monoid of endomorphisms of \( \hat{\mathcal{P}aB} \) which induce the identity on objects, it suffices to prove that any endomorphism of \( \mathcal{P}aB \) is homotopic to one which induces the identity on objects. The operad \( \text{Ob}(\mathcal{P}aB) \) is freely generated as an operad by the object (12) in \( \text{Ob}(\mathcal{P}aB(2)) \), thus the restriction of a morphism \( u : \mathcal{P}aB \to \mathcal{P}aB \) on objects is entirely determined by where it sends the object (12). The image of this object can be either (12) in which case \( u \) induces the identity on objects or (21). Assume that \( u(12) = (21) \). We want to construct a map \( v : \hat{\mathcal{P}aB} \to \hat{\mathcal{P}aB} \) which is the identity on objects and a homotopy \( h \) from \( u \) to \( v \). In this context, a homotopy is just a natural transformation \( h \) from \( u \) to \( v \). Let us pick a morphism (21) \to (12) in \( \hat{\mathcal{P}aB} \). We define \( h(12) : u(12) = (21) \to v(12) = (12) \) to be this morphism. This induces in a unique way a map \( h(x) : u(x) \to v(x) \) for any object \( x \) of \( \mathcal{P}aB(n) \) and any \( n \). Now if \( a : x \to y \) is a morphism in \( \mathcal{P}aB(n) \), we define \( v(a) \) to be \( h(y)u(a)h(x)^{-1} \). The map \( v \) preserves the operad composition. Indeed, if \( a : x \to y \) is a morphism in \( \mathcal{P}aB(n) \) and \( b : z \to t \) is a morphism in \( \mathcal{P}aB(m) \) and \( i \in \{1, \ldots, n\} \), using the fact that \( u \) and \( h \) preserve the operad structure, we have
\[ v(a) \circ_i v(b) = h(x \circ_i z)u(a \circ_i b)h(x \circ_i z)^{-1} = v(a \circ_i b) \]

In order to prove the injectivity, it suffices to prove that the composite:
\[ \hat{G} \hat{T} \to \text{End}_{\pi \hat{\text{Op}} \hat{G}}(\hat{\mathcal{P}aB}) \to \text{End}_{\pi \hat{G}}(\hat{\mathcal{P}aB}) \]
is injective.

Since \( \mathcal{P}aB(3) \) is a fibrant (by proposition 3.40) and cofibrant object in \( \hat{\mathcal{G}} \), it suffices to show that the composite
\[ \hat{G} \hat{T} \to \text{End}_{\pi \hat{G}}(\hat{\mathcal{P}aB}(3)) = \text{End}_{\pi \hat{G}}(* \ll / \hat{K}_3) = \text{End}_{\pi \text{Grp}}(\hat{K}_3) \]
is injective but this follows from proposition 6.7. \( \square \)

7. Proof of main theorem

Case of groupoids. Note that if \( \mathcal{P} \) is an operad in \( \hat{\mathcal{G}} \), the symmetric sequence \( \{ \mathcal{P}(n)^{[k]} \} \) has the structure of an operad in \( \hat{\mathcal{G}} \) for any \( k \). Thus, for \( \mathcal{O} \) and \( \mathcal{P} \) two operads in \( \hat{\mathcal{G}} \), we can define a simplicial set \( \text{Map}_{\hat{\text{Op}} \hat{G}}(\mathcal{O}, \mathcal{P}) \) whose \( k \)-simplices are the map of operads in profinite groupoids from \( \mathcal{O} \) to \( \mathcal{P}^{[k]} \).

7.1. Proposition. There is a weak equivalence of monoids in \( \mathcal{S} \).
\[ \text{Map}_{\hat{\text{Op}} \hat{G}}(\hat{\mathcal{P}aB}, \mathcal{P}aB) \simeq \text{Map}_{\text{WOp}_G}(N^\mathcal{P} \mathcal{P}aB, N^\mathcal{P} \mathcal{P}aB) \]

Proof. We have an isomorphism
\[ \text{Map}_{\hat{\text{Op}} \hat{G}}(\hat{\mathcal{P}aB}, \mathcal{P}aB) \simeq \text{Map}_{\text{Op}_G}(\mathcal{P}aB, [\mathcal{P}aB]) \]
Since \( \mathcal{P}aB \) is cofibrant by corollary 5.7 in \( \text{Op}_G \) and \( [\mathcal{P}aB] \) is fibrant, we have
\[ \text{Map}_{\text{Op}_G}(\mathcal{P}aB, [\mathcal{P}aB]) \simeq \text{Map}_{\text{Op}_G}(\mathcal{P}aB, [\mathcal{P}aB]) \]

\(^2\)The argument for the surjectivity was explained to me by Benoît Fresse
The functor \( N^\Psi : \text{OpG} \to \text{WOpG} \) is a weak equivalence preserving right Quillen equivalence by proposition \( A.13 \), thus we have

\[
\text{Map}_{\text{OpG}}(\overline{\mathcal{P}aB}, |\overline{\mathcal{P}aB}|) \simeq \text{Map}^h_{\text{WOpG}}(N^\Psi \overline{\mathcal{P}aB}, N^\Psi |\overline{\mathcal{P}aB}|) \simeq \text{Map}^h_{\text{WOpG}}(\overline{N^\Psi \mathcal{P}aB}, N^\Psi \overline{\mathcal{P}aB})
\]

Finally since \( N^\Psi \overline{\mathcal{P}aB} \) is isomorphic to \( N^\Psi \mathcal{P}aB \) by proposition \( 3.23 \), we have a weak equivalence

\[
\text{Map}_{\text{OpG}}(\overline{\mathcal{P}aB}, |\overline{\mathcal{P}aB}|) \simeq \text{Map}^h_{\text{WOpG}}(\overline{N^\Psi \mathcal{P}aB}, N^\Psi \overline{\mathcal{P}aB})
\]

This implies immediately the groupoid versions of our main theorem

### 7.2. Theorem

The map \( \hat{G}T \to \text{End}_{\text{OpG}}(\overline{\mathcal{P}aB}) \) induces an isomorphism of monoids

\[
\hat{G}T \to \text{End}_{\text{WOpG}}(N^\Psi \overline{\mathcal{P}aB})
\]

**Proof.** We can apply \( \pi_0 \) on both sides of the equivalence proved in the previous proposition. By theorem \( 6.8 \), we have an isomorphism

\[
\pi_0 \text{Map}_{\text{OpG}}(\overline{\mathcal{P}aB}, \overline{\mathcal{P}aB}) \cong \hat{G}T
\]

**From groupoids to spaces.** We now prove our main theorem.

### 7.3. Proposition

There is a weak equivalence of simplicial monoids

\[
\text{Map}^h_{\text{WOpS}}(\widetilde{E_2}, \widetilde{E_2}) \simeq \text{Map}^h_{\text{WOpG}}(N^\Psi \overline{\mathcal{P}aB}, N^\Psi \overline{\mathcal{P}aB})
\]

**Proof.** The weak operad \( N^\Psi B\overline{\mathcal{P}aB} \) is weakly equivalent to \( E_2 = N^\Psi E_2 \) by proposition \( 5.2 \), thus, we want to compute the monoid \( \text{Map}^h_{\text{WOpS}}(N^\Psi \overline{\mathcal{P}aB}, N^\Psi \overline{\mathcal{P}aB}) \).

The unit map \( \overline{\mathcal{P}aB} \to |\overline{\mathcal{P}aB}| \) induces a map in \( \text{WOpS} \):

\[
N^\Psi B\overline{\mathcal{P}aB} \to N^\Psi B|\overline{\mathcal{P}aB}| \cong |N^\Psi B\overline{\mathcal{P}aB}|
\]

where the last isomorphism comes from the observation that \(-|-\) commutes with \( N^\Psi \) and \( B \).

This map is adjoint to a map

\[
N^\Psi \overline{B\mathcal{P}aB} \to N^\Psi B\overline{\mathcal{P}aB}
\]

We claim that this map is a weak equivalence in \( \text{WOpS} \). It suffices to check that it is a levelwise weak equivalence. For a given \( T_n \in \Psi \), this map is given by

\[
\overline{BC} \to \overline{B\mathcal{C}}
\]

for some groupoid \( C \) which is a finite product of groupoids of the form \( \mathcal{P}aB(n) \) for various \( n \)’s. Such a groupoid is good by corollary \( 4.12 \) and corollary \( 4.11 \). Thus, according to proposition \( 4.9 \), the map \( \overline{BC} \to B\mathcal{C} \) is a weak equivalence.

Hence, we have a weak equivalence of monoids

\[
\text{Map}^h_{\text{WOpS}}(N^\Psi B\overline{\mathcal{P}aB}, N^\Psi B\overline{\mathcal{P}aB}) \simeq \text{Map}^h_{\text{WOpS}}(N^\Psi \overline{B\mathcal{P}aB}, N^\Psi B\overline{\mathcal{P}aB})
\]

There is a natural isomorphism \( N^\Psi B\emptyset \cong BN^\Psi \emptyset \) for any operad \( \emptyset \) in profinite groupoids, therefore we have an equivalence of monoids

\[
\text{Map}^h_{\text{WOpS}}(N^\Psi B\overline{\mathcal{P}aB}, N^\Psi B\overline{\mathcal{P}aB}) \simeq \text{Map}^h_{\text{WOpS}}(BN^\Psi \overline{\mathcal{P}aB}, BN^\Psi \overline{\mathcal{P}aB})
\]
Since $BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B}$ is a weak operad, we have
\[
\text{Map}^h_{\text{WOpS}}(BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B}, BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B}) \simeq \text{Map}^h_{\text{PopS}}(BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B}, BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B})
\]
Using the Quillen adjunction $(\pi, B)$, we have a weak equivalence
\[
\text{Map}^h_{\text{PopS}}(BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B}, BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B}) \simeq \text{Map}^h_{\text{Pop}\mathcal{G}}(\pi BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B}, N^\Psi \tilde{\mathcal{P}}_B\mathcal{B})
\]
which according to proposition 4.7 induces a weak equivalence
\[
\text{Map}^h_{\text{PopS}}(BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B}, BN^\Psi \tilde{\mathcal{P}}_B\mathcal{B}) \simeq \text{Map}^h_{\text{Pop}\mathcal{G}}(N^\Psi \tilde{\mathcal{P}}_B\mathcal{B}, N^\Psi \tilde{\mathcal{P}}_B\mathcal{B})
\]
Finally, using the fact that $N^\Psi \tilde{\mathcal{P}}_B\mathcal{B}$ is fibrant in $\text{WOp}\mathcal{G}$, we have proved that there is a weak equivalence
\[
\text{Map}^h_{\text{WOpS}}(N^\Psi \tilde{\mathcal{P}}_B\mathcal{B}, N^\Psi \tilde{\mathcal{P}}_B\mathcal{B}) \simeq \text{Map}^h_{\text{WOp}\mathcal{G}}(N^\Psi \tilde{\mathcal{P}}_B\mathcal{B}, N^\Psi \tilde{\mathcal{P}}_B\mathcal{B})
\]
which concludes the proof. 

Our main theorem now follows trivially:

7.4. Theorem. There is an isomorphism of monoids
\[
\tilde{\mathcal{G}} \mathcal{T} \cong \text{End}_{\text{Ho WOpS}}(\tilde{E}_2)
\]

Proof. According to the previous proposition, we have an isomorphism
\[
\text{End}_{\text{Ho WOpS}}(\tilde{E}_2) \cong \text{End}_{\text{Ho WOp}\mathcal{G}}(N^\Psi \tilde{\mathcal{P}}_B\mathcal{B})
\]
Using theorem 7.2, we deduce the result.

Higher homotopy groups. In this subsection, we compute the higher homotopy groups of the space of homotopy automorphisms of $\tilde{E}_2$. First, according to proposition 7.3, we see that the mapping space $\text{Map}^h_{\text{WOpS}}(\tilde{E}_2, \tilde{E}_2)$ is 1-truncated (i.e. does not have homotopy groups in degree higher than 1).

We first make the computation of the homotopy groups of the space of homotopy automorphisms of the simplicial operad $\tilde{E}_2$.

7.5. Theorem. The simplicial monoid $\text{Map}^h(\tilde{E}_2, \tilde{E}_2)$ is weakly equivalent to the (singular complex of the) topological group $O(2, \mathbb{R})$.

Proof. For $M$ a fibrant simplicial monoid, we denote by $M^{h_\mathcal{X}}$ the inverse image of $\pi_0(M)^\mathcal{X}$ along the map $M \to \pi_0(M)$. This is a grouplike simplicial monoid.

Since the category of groupoids is a simplicial model category in which all objects are cofibrant and fibrant, we have
\[
\text{Map}_G(* \amalg \mathbb{Z}, * \amalg \mathbb{Z}) \simeq \text{Map}_G(* \amalg \mathbb{Z}, * \amalg \mathbb{Z})
\]
Thus, using the fact that $B : \mathcal{G} \to S$ is derived fully faithful, we find that
\[
\text{Map}_G(* \amalg \mathbb{Z}, * \amalg \mathbb{Z}) \simeq \text{Map}_G^h(B\mathbb{Z}, B\mathbb{Z})
\]
Since $B\mathbb{Z}$ is a cofibrant-fibrant model for $S^1$, this last monoid is weakly equivalent to $\text{Map}_S(S^1, S^1)$. It is well-known that $\text{Map}_S(S^1, S^1)^{h_\mathcal{X}}$ is weakly equivalent to $O(2, \mathbb{R})$.

We have a weak equivalence $\tilde{\mathcal{P}}_B(\mathbb{2}) \to * \amalg K_2 \cong * \amalg \mathbb{Z}$. Therefore, we also have a weak equivalence between $O(2, \mathbb{R})$ and $\text{Map}(\tilde{\mathcal{P}}_B(\mathbb{2}), \tilde{\mathcal{P}}_B(\mathbb{2}))^{h_\mathcal{X}}$.

We know that $B\tilde{\mathcal{P}}_B \simeq \tilde{E}_2$, thus we have
\[
\text{Map}^h_{\text{OpS}}(\tilde{E}_2, \tilde{E}_2) \simeq \text{Map}^h_{\text{OpS}}(B\tilde{\mathcal{P}}_B, B\tilde{\mathcal{P}}_B)
\]
We can prove exactly as proposition A.14 that

\[ \text{Map}^h_{\text{OpG}}(B\text{PaB}, B\text{PaB}) \cong \text{Map}^h_{\text{OpG}}(\text{PaB}, \text{PaB}) \]

Since \( \text{OpG} \) is a simplicial model category and \( \text{PaB} \) is cofibrant by corollary 5.7 and fibrant, we have

\[ \text{Map}^h_{\text{OpG}}(\text{PaB}, \text{PaB}) \cong \text{Map}_{\text{OpG}}(\text{PaB}, \text{PaB}) \]

By evaluating in degree 2, we get a map

\[ \text{Map}_{\text{OpG}}(\text{PaB}, \text{PaB}) \to \text{Map}_{\text{G}}(\text{PaB}(2), \text{PaB}(2)) \]

We claim that this map induces a weak equivalence

\[ \text{Map}_{\text{OpG}}(\text{PaB}, \text{PaB}) \to \text{Map}_{\text{G}}(\text{PaB}(2), \text{PaB}(2))^{h_X} \cong O(2, \mathbb{R}) \]

Drinfel’d in [Dri90, Proposition 4.1.] proves that the monoid of endomorphism of \( \text{PaB} \) which induces the identity on objects is isomorphic to \( \mathbb{Z}/2 \). Thus, we have a map

\[ \mathbb{Z}/2 \to \text{Map}_{\text{OpG}}(\text{PaB}, \text{PaB}) \]

One can prove exactly as theorem 6.8 that this map induces an isomorphism

\[ \mathbb{Z}/2 \cong \pi_0 \text{Map}_{\text{OpG}}(\text{PaB}, \text{PaB}) \]

Moreover, by definition, the non-trivial element of \( \mathbb{Z}/2 \) induces the unique non-trivial automorphism of \( \text{PaB}(2) \) in the homotopy category of groupoids. This means that the map 7.1 is an isomorphism on \( \pi_0 \).

Now, we want to compute the effect of 7.1 on \( \pi_1 \). Note that according to the previous paragraph, \( \text{Map}_{\text{OpG}}(\text{PaB}, \text{PaB}) \) is a group-like monoid, thus it suffices to prove that the map 7.1 induces an isomorphism on \( \pi_1 \) based at the unit.

The group \( G = \pi_1(\text{Map}_{\text{OpG}}(\text{PaB}, \text{PaB}), \text{id}) \) is the group of natural transformations of the identity map \( \text{PaB} \to \text{PaB} \).

More explicitly, such a natural transformation is the data of an element \( h(x) \in \text{PaB}(n)(x, x) \) for each object \( x \) of \( \text{PaB}(n) \) and each \( n \) which satisfy the relations

- The equation \( h(x \circ_i y) = h(x) \circ_i h(y) \) holds whenever both sides are defined.
- For all \( u : x \to y \) in \( \text{PaB}(n) \), we have \( h(y)uh(x)^{-1} = u \)

We have a map \( \epsilon : G \to \mathbb{Z} = \text{Aut}_{\text{PaB}}((12)) \) sending \( \{h(x)\}_{x \in \text{Ob}(\text{PaB})} \) to \( h((12)) \). Since any object of \( \text{PaB}(n) \) for any \( n \) can be obtained as iterated composition of the object \( (12) \), the map \( G \to \mathbb{Z} \) is injective. Moreover, this map \( \epsilon : G \to \mathbb{Z} \) is also the map obtained by applying \( \pi_1 \) to the equation 7.1.

In order to prove that \( \epsilon \) is surjective, it suffices to construct a section. We can see \( K_n \) as the fundamental group of \( \text{Conf}(n, \mathbb{C}) \) based at \( c_0 = (-n + 1, -n + 3, \ldots, n - 3, n - 1) \). For each \( \theta \in S^1 = \mathbb{R}/2\pi\mathbb{Z} \), we can form \( e^\theta c_0 \in \text{Conf}(n, \mathbb{C}) \) to be \( e^\theta c_0 \). This defines a map \( S^1 \to \text{Conf}(n, \mathbb{C}) \) sending 0 to \( e^\theta c_0 \). Taking the fundamental group, we get a map \( \mathbb{Z} \to K_n \). This maps factors through the center of \( K_n \). Alternatively, the generator of \( \mathbb{Z} \) gives us a natural transformation of the identity map \( * \to K_n \to * \to K_n \) for each \( n \). This obviously extends to a natural transformation of the identity map \( \text{PaB}(n) \to \text{PaB}(n) \). All these natural transformations \( \text{PaB}(n) \to \text{PaB}(n) \) are compatible with the operadic structure. A version of this statement can be found in Wahl’s thesis (see [Wah01, Section 1.3.]) where the author proves that a certain operad in groupoid that she denotes \( \left\{ \phi^\theta_{P, \beta} \right\} \) has an action of the bimonoid object in groupoids \( * \to \mathbb{Z} \). The operad \( \left\{ \phi^\beta_{P, \beta} \right\} \) is a very close relative of the operad \( \text{PaB} \), it encodes braided monoidal categories with strictly associative multiplication. It is easy to verify that the \( * \to \mathbb{Z} \)-action constructed by Wahl extends to a \( * \to \mathbb{Z} \)-action on \( \text{PaB} \).
In other words, we have exhibited a map \( Z \rightarrow G \) and by examining what it does in degree 2, we see that it is a section of \( \epsilon \). Hence the map \( 7.1 \) induces an isomorphism on \( \pi_0 \) and \( \pi_1 \). Since both sides are truncated spaces, this proves that \( 7.1 \) is a weak equivalence. \( \square \)

Now, we treat the profinite case.

**7.6. Theorem.** The component of the identity in \( \text{Map}^b_{\text{WOpS}}(\tilde{E}_2, \tilde{E}_2)^{h \times} \) is weakly equivalent to \( B[\tilde{Z}] \).

**Proof.** Using propositions \( 7.1 \) and \( 7.3 \), we see that we have a weak equivalence

\[
\text{Map}^b_{\text{WOpS}}(\tilde{E}_2, \tilde{E}_2)^{h \times} \simeq \text{Map}_{\text{OpG}}(\tilde{\mathcal{A}}_B, \tilde{\mathcal{A}}_B)^{h \times}
\]

Thus, it suffices to prove that the fundamental group of \( \text{Map}^b_{\text{OpG}}(\tilde{\mathcal{A}}_B, \tilde{\mathcal{A}}_B)^{k \times} \) based at the identity is \( \tilde{Z} \).

We proceed as in theorem 7.5, there is an evaluation map

\[
\text{Map}_{\text{OpG}}(\tilde{\mathcal{A}}_B, \tilde{\mathcal{A}}_B)^{h \times} \rightarrow \text{Map}_G(\tilde{\mathcal{A}}_B(2), \tilde{\mathcal{A}}_B(2))^{h \times}
\]

Taking \( \pi_1 \), we get a map

\[
\pi_1(\text{Map}_{\text{OpG}}(\tilde{\mathcal{A}}_B, \tilde{\mathcal{A}}_B), \text{id}) \rightarrow \pi_1(\text{Map}_G(\tilde{\mathcal{A}}_B(2), \tilde{\mathcal{A}}_B(2)), \text{id})
\]

Since \( \tilde{\mathcal{A}}_B(2) \) is cofibrant fibrant in \( \widehat{\mathcal{G}} \), we have

\[
\text{Map}_G(\tilde{\mathcal{A}}_B(2), \tilde{\mathcal{A}}_B(2)) \simeq \text{Map}^{h}_G(* \parallel \tilde{Z}, * \parallel \tilde{Z})
\]

Using the Quillen adjunction \( G \rightrightarrows \widehat{G} \), we have

\[
\text{Map}^{h}_G(* \parallel \tilde{Z}, * \parallel \tilde{Z}) \simeq \text{Map}^{h}_G(* \parallel \tilde{Z}, * \parallel |\tilde{Z}|)
\]

Since \( |\tilde{Z}| \) is commutative, the fundamental group of this last space based at the completion map \( * \parallel \tilde{Z} \rightarrow * \parallel |\tilde{Z}| \) is isomorphic to \( |\tilde{Z}| \).

Hence, we have a map

\[
\pi_1(\text{Map}_{\text{OpG}}(\tilde{\mathcal{A}}_B, \tilde{\mathcal{A}}_B), \text{id}) \rightarrow |\tilde{Z}|
\]

Exactly as in theorem 7.5, we prove that this map is injective.

In the proof of theorem 7.5, we construct a section of this map by constructing a natural transformation of the identity map \( \mathcal{A}_B \rightarrow \tilde{\mathcal{A}}_B \). In other words, we construct a map \( \mathcal{A}_B \rightarrow \mathcal{A}_B^{f[1]} \) such that the composite of that map with the two evaluation maps \( \mathcal{A}_B^{f[1]} \rightarrow \mathcal{A}_B \) is the identity. This natural transformation induces a natural transformation

\[
\mathcal{A}_B \rightarrow \mathcal{A}_B^{f[1]}
\]

which can be composed with the map \( \tilde{\mathcal{A}}_B^{f[1]} \rightarrow \tilde{\mathcal{A}}_B^{f[1]} \) which is adjoint to the obvious map \( \mathcal{A}_B^{f[1]} \rightarrow |\mathcal{A}_B^{f[1]}| \simeq |\tilde{\mathcal{A}}_B^{f[1]}| \). In the end, we get a map

\[
\tilde{\mathcal{A}}_B \rightarrow \tilde{\mathcal{A}}_B^{f[1]}
\]

in which both evaluation are the identity \( \tilde{\mathcal{A}}_B \rightarrow \tilde{\mathcal{A}}_B \). Using the hom-cotensor adjunction in \( \text{OpG} \), we have constructed a map from \( * \parallel \tilde{Z} \) to the groupoid of natural transformations of the identity map \( \mathcal{A}_B \rightarrow \tilde{\mathcal{A}}_B \). Since the target is a profinite group, this map extends to a map

\[
|\tilde{Z}| \rightarrow \pi_1(\text{Map}_{\text{OpG}}(\tilde{\mathcal{A}}_B, \tilde{\mathcal{A}}_B), \text{id})
\]
It is also straightforward to check that this map is a section of the map
\[ \pi_1(\Map_{\mathcal{O}^G}(\hat{\mathcal{P}}a\mathcal{B}, \hat{\mathcal{P}}a\mathcal{B}), \text{id}) \to |\hat{\mathcal{Z}}| \]
constructed above by looking at its action in degree 2.

To summarize the previous two theorems, we have the following commutative diagram:

\[
\begin{array}{c}
1 \\
\downarrow \\
\text{Map}^h_{\mathcal{W}^G}(\hat{E}_2, \hat{E}_2)^{h\times} \\
\downarrow \\
\hat{\mathcal{S}}_1 \\
\end{array}
\rightarrow
\begin{array}{c}
\text{Map}^h_{\mathcal{W}^G}(\hat{E}_2, \hat{E}_2)^{h\times} \\
\downarrow \\
\text{GT} \\
\end{array}
\rightarrow
\begin{array}{c}
\hat{\mathcal{S}}_1 \\
\downarrow \\
1 \\
\end{array}
\]

In this diagram, each row is a split exact sequence of grouplike simplicial monoids. The first map in each row is the inclusion of the component of the identity. The second map is the map from the group of homotopy automorphisms to its space of components. The map \( \mathbb{Z}/2 \to \text{GT} \) can be checked to be the complex conjugation map \( \mathbb{Z}/2 \to \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \) composed with the inclusion \( \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \text{GT} \).

**Alternative version of the main result.** Profinite completion is the left adjoint to the functor
\[ |\_| : \hat{\mathcal{S}} \to \mathcal{S} \]
which forgets the topology and that is the approach we chose. However, for some authors like in [Sul74], profinite completion should really be the endo-functor \( \mathcal{S} \to \mathcal{S} \) sending \( X \) to \( |R\hat{X}| \) where \( R \) is a fibrant replacement functor in \( \hat{\mathcal{S}} \). It is not true that \( |\_| \) is fully faithful. Nevertheless, our main result remains true for this alternative definition of profinite completion.

7.7. **Definition.** A profinite group is **strongly complete** if any normal subgroup of finite index is open. Equivalently a profinite group is strongly complete if it is isomorphic to the profinite completion of its underlying discrete group.

7.8. **Proposition.** For any \( n \), the profinite group \( \hat{K}_n \) is strongly complete.

**Proof.** According to the main theorem of [NS07], it suffices to prove that \( \hat{K}_n \) is finitely generated as a topological group (i.e. there exists a map \( F_s \to K_n \) with dense image). It is well-known that the pure braid groups \( K_n \) are finitely generated. This means that for any \( n \), there is an \( s \) and a surjection \( F_s \to K_n \). The profinite completion functor preserves surjective maps which implies that \( \hat{K}_n \) is finitely generated.

7.9. **Definition.** We say that a profinite groupoid \( C \) with finite set of objects is **strongly complete** if for any object \( x \) of \( C \), the group \( C(x, x) \) is a strongly complete profinite group.

7.10. **Proposition.** Let \( C \) be a strongly complete profinite groupoid. Then the map \( |\hat{C}| \to C \) is an isomorphism.

**Proof.** The functor \(|\_|\) preserves finite coproducts. The completion functor preserves finite coproducts as well since it is a left adjoint. We are therefore reduced to proving the result for a connected profinite groupoid. A connected profinite groupoid is isomorphic to \( G[S] \) for some profinite group \( G \). Thus, it suffices to prove the result for \( G[S] \) for \( S \) finite and \( G \) strongly complete. But in that case, we have an isomorphism
\[ |\hat{G[S]}| \cong |\hat{G}|[S] \cong G[S] \]
7.11. Proposition. Let X and Y be two weak operads in $\hat{G}$ such that for all $T_a$ in $\Psi$, $X(T_a)$ and $Y(T_a)$ are strongly complete, then the map
\[
\text{Map}^h_{\text{WOp}}(BX, BY) \to \text{Map}^h_{\text{WOpS}}(|BX|, |BY|)
\]
is a weak equivalence.

Proof. This map fits in the following commutative diagram
\[
\begin{array}{ccc}
\text{Map}^h_{\text{WOp}}(X, Y) & \to & \text{Map}^h_{\text{WOpS}}(BX, BY) \\
\downarrow & & \downarrow \\
\text{Map}^h_{\text{WOp}}(|X|, |Y|) & \to & \text{Map}^h_{\text{WOpS}}(|BX|, |BY|)
\end{array}
\]
The two horizontal maps are weak equivalences. Therefore, it suffices to prove that
\[
\text{Map}^h_{\text{WOp}}(X, Y) \to \text{Map}^h_{\text{WOpG}}(|X|, |Y|)
\]
is a weak equivalence. Alternatively, by theorem 1.3, it suffices to prove that $X \to \hat{X}$ is a weak equivalence of weak operads in profinite groupoids. By definition of a strongly complete profinite groupoid, this is even an isomorphism. □

7.12. Corollary. Let $R\hat{E}_2$ be a fibrant replacement of $\hat{E}_2$ in $\text{WOpS}$. Then there is a weak equivalence of monoids
\[
\text{Map}^h_{\text{WOpS}}(\hat{E}_2, \hat{E}_2) \to \text{Map}^h_{\text{WOpS}}(|R\hat{E}_2|, |R\hat{E}_2|)
\]
Proof. It suffices to apply the previous proposition to $X = Y = N^\Psi \hat{P}aB$. □

Remark about the $\ell$-completion. Our result also has a pro-$\ell$ version for any prime number $\ell$. There is a model structure $\hat{S}_{\ell}$ on $\hat{S}$ due to Morel (see [Mor96]) which encodes the $\infty$-category of pro-objects in the $\infty$-category of spaces which are truncated and have homotopy groups that are finite $\ell$-groups. There is a pro-$\ell$ completion functor $X \mapsto \hat{X}_{\ell}$ from $S$ to $\hat{S}_{\ell}$. This induces a left Quillen functor
\[
\text{WOpS} \to \text{WOpS}_{\ell}
\]
One can form the pro-$\ell$ completion of a group and more generally a groupoid. First, we define the category $\ell G$ of groupoids that are finite and in which each automorphism group is an $\ell$-group. Given a groupoid $C$, its pro-$\ell$ completion is the finite limit preserving functor $D \mapsto G(C, D)$ seen as an object of $\text{Pro}(\ell G)$. One can form the operad in pro-$\ell$ groupoids $\hat{P}aB_{\ell}$ by applying this functor levelwise to $\hat{P}aB$. We define $\hat{G}_{\ell}$ to be the monoid of endomorphisms of $\hat{P}aB_{\ell}$ that induces the identity on objects. Then we have the following result whose proof is exactly the same as the proof of theorem 7.4.

7.13. Theorem. There is an isomorphism of monoids
\[
\text{End}_{\text{WOpS}}(\hat{E}_2_{\ell}) \cong \hat{G}_{\ell}
\]

Appendix A. Weak operads

Unitary operads. Let $C$ be a category with finite products. We assume that the reader is familiar with the notion of operad. In this work, all operads will be unitary operads. A unitary operad, also called a reduced operad by Berger and Moerdijk in [BM03] is an operad $O$ with $O(0) \cong *$. We denote
by $\text{OpC}$ the category of unitary operads and simply call them operads. If $\emptyset$ is an operad, for each $i \in \{1, \ldots, n\}$, we get a partial composition map

$$\emptyset(n) \cong \emptyset(n) \times \emptyset(0) \xrightarrow{\emptyset_i} \emptyset(n-1)$$

Using these operations, Fresse observes in [Fre15a] that one can give the collection $\{\emptyset(n)\}_{n \geq 1}$ the structure of a contravariant functor on the category $\Lambda_{>0}$ whose objects are the finite sets $\{1, \ldots, n\}$ with $n \geq 1$ and whose morphisms are injections. This can be used to turn the condition of being unitary into a structure on operads without arity zero operations. More precisely, we have the following definition:

A.1. Definition (Fresse). A $\Lambda$-operad in $\mathbf{C}$ is a contravariant functor $\emptyset$ from $\Lambda_{>0}$ to $\mathbf{C}$ together with the data of an operad structure (without arity zero operations) on the underlying symmetric sequence $\{\emptyset(n)\}_{n \in \mathbb{N}}$. Moreover these two structures are required to satisfy the condition (b) of [Fre15a, Proposition 3.2.16].

A.2. Remark. This definition can be found in [Fre15a, 3.2.17.]. Note that Fresse has an additional piece of structure given by an augmentation and an additional relation. However, in our context, the symmetric monoidal structure is given by the categorical product, in particular, the unit is the terminal object. This implies that there is a unique augmentation that satisfies Fresse’s definition and moreover, it automatically satisfies the condition (a) of [Fre15a, Proposition 3.2.16]. For this reason, we can safely drop it from the definition and still obtain the same category.

The fundamental result is that the functor that sends a unitary operad to its underlying $\Lambda$-operad is an equivalence of categories (see [Fre15a, Theorem 3.2.18.]). The advantage of $\Lambda$-operads over operads is that they can be modelled by an algebraic theory. This will be important in the next paragraph. Note that in [Fre15a], the above equivalence is stated as an equivalence between unitary operads and $\Lambda$-operads with an augmentation to the commutative operad. For the reason explained in the remark above, the category of $\Lambda$-operads over the commutative operad is just the category of $\Lambda$-operads in our context.

The algebraic theory of operads. The important fact for us will be that the theory of (unitary) operads is definable by an algebraic theory.

A.3. Definition. Let $S$ be a set. An $S$-sorted algebraic theory is a category with products $\Phi$ whose objects are $T_a$ for each finite sequence $a = \{a_1, \ldots, a_n\}$ of elements of $S$. Moreover, we require the existence of an isomorphism

$$T_a \cong T_{a_1} \times T_{a_2} \times \ldots \times T_{a_n}$$

A.4. Definition. Let $\Phi$ be an algebraic theory. Let $\mathbf{C}$ be a category with products. The category of $\Phi$-algebras in $\mathbf{C}$ is the category of product preserving functors from $\Phi$ to $\mathbf{C}$.

There is a forgetful functor

$$U : \text{OpSet} \to \text{Set}^\mathbb{N}$$

that sends an operad $\emptyset$ to the collection $\{\emptyset(n)\}_{n \geq 1}$. This functor has a left adjoint. To understand this left adjoint, we can decompose the above forgetful functor as the composite of the forgetful functor $\text{OpSet} \to \text{Fun}(\Lambda_{>0}^{\text{op}}, \text{Set})$ with the forgetful functor $\text{Fun}(\Lambda_{>0}^{\text{op}}, \text{Set})$. Each of these two forgetful functors has a left adjoint. The left adjoint of the forgetful functor $\text{OpSet} \to \text{Fun}(\Lambda_{>0}^{\text{op}}, \text{Set})$ is denoted $\emptyset$ by Fresse. Its existence is the content of [Fre15a, Theorem 3.3.2.]. To construct the other left adjoint, we can see the set $\mathbb{N}$ as a category with only identities. There is a functor $\mathbb{N} \to \Lambda_{>0}$ that sends $n$ to $\{1, \ldots, n\}$. It follows that the forgetful functor $\text{Fun}(\Lambda_{>0}^{\text{op}}, \text{Set}) \to \text{Set}^\mathbb{N}$ has a left adjoint given by left Kan extension along $\mathbb{N} \to \Lambda_{>0}^{\text{op}}$. We denote by $F$ the composite of these two left adjoints. In conclusion, we have an adjunction

$$F : \text{Set}^\mathbb{N} \rightleftarrows \text{OpSet} : U$$
Now, we construct an \( N \)-sorted theory \( \Psi^{\text{op}} \). First, we associate to a sequence \( a = \{a_1, \ldots, a_n\} \) of integers with the objects of \( \text{Set}^N \) the element \( S_a \) of \( \text{Set}^N \) given by
\[
S_a(k) = \bigsqcup_{i, a_i = k}^* \quad \text{for } k \in [n].
\]
Notice that we have an isomorphism
\[
(A.1) \quad S_a \cong S_{a_1} \sqcup \ldots \sqcup S_{a_n}
\]
Now, we define \( \Psi \) to be the category whose objects are \( T_a \) for \( a \) a finite sequence of integers and with morphisms
\[
\Psi(T_a, T_b) := \text{OpSet}(\mathbb{F}S_a, \mathbb{F}S_b)
\]
The composition in \( \Psi \) are given by composition in \( \text{OpSet} \). The category \( \Psi \) is thus a full subcategory of the category \( \text{OpSet} \). Equation \( A.1 \) implies that \( \mathbb{F}S_a \) is isomorphic to the coproduct in \( \text{OpSet} \) of the \( \mathbb{F}S_{a_i} \). This immediately implies that \( \Psi^{\text{op}} \) is an \( N \)-sorted algebraic theory.

**A.5. Proposition.** The category of \( \Psi^{\text{op}} \)-algebras in sets is equivalent to the category \( \text{OpSet} \).

**Proof.** This proposition is quite general and we only sketch the proof. There is a functor \( N^\Psi : \text{OpSet} \to \text{Alg}^{\Psi^{\text{op}}} \) which sends \( O \) to \( T_a \mapsto \prod_i O(a_i) \). This functor is clearly faithful.

We introduce a simplifying notation. Given \( a \) a finite sequence of integers and \( X \) an object in \( \text{Set}^N \), we denote by \( X(a) \) the set \( \text{Set}^N(S_a, X) \).

Looking at the definition, we see that an operad is an object \( O \) of \( \text{Set}^N \) equipped with a collection of operations of the form
\[
(O(a) \to O(b))
\]
that satisfy several relations which can all be expressed by saying that two maps
\[
(O(c) \to O(d))
\]
constructed from the operations are equal.

Since \( \mathbb{F}S_a \) is the object representing \( O \mapsto O(a) \) each of the operation \( \text{A.2} \) must be represented by a map \( \mathbb{F}S_b \to \mathbb{F}S_a \). This implies that \( N^\Psi \) is full. Indeed, a map of operads is a map of collections \( \{O(a)\}_{a \in N} \to \{P(a)\}_{a \in N} \) commuting with the operations \( \text{A.2} \). Since these operations are represented by maps in \( \Psi \), any map of presheaves \( N^\Psi O \to N^\Psi P \) restricts to a map \( O \to P \).

Moreover, the relations satisfied by an operad are in particular valid for \( O = \mathbb{F}S_e \) for any finite sequence of integer \( e \). Thus by Yoneda’s lemma in \( \Psi \), the two maps \( \mathbb{F}S_d \to \mathbb{F}S_e \) representing the relation \( \text{A.3} \) are equal. Hence, we see that given any functor \( X : \Psi^{\text{op}} \to \text{Set} \) preserving products, the collection \( \{X(T_a)\}_{a \in N} \) will satisfy the axioms of an operad. In other words, the functor \( N^\Psi \) is essentially surjective. \( \square \)

**Preoperads.**

**A.6. Definition.** Let \( C \) be a category with finite products. We define the category \( \text{POpC} \) of \textit{preoperads} in \( C \) to be the category of functors from \( \Psi^{\text{op}} \) to \( C \). We define the category \( \text{OpC} \) to be the full subcategory of \( \text{POpC} \) spanned by the product preserving functors from \( \Psi^{\text{op}} \) to \( C \).

**A.7. Remark.** There is a slight conflict of notation with the previous subsection since the category \( \text{OpSet} \) is not isomorphic to the category of product preserving functors \( \Psi^{\text{op}} \to \text{Set} \) but merely equivalent to it.

We will denote the inclusion \( \text{OpC} \to \text{POpC} \) by the symbol \( N^\Psi \) and call it the operadic nerve.
A.8. Proposition. Let $C$ be a combinatorial (resp. cocombinatorial) model category. The category $\text{POpC}$ has a combinatorial (resp. cocombinatorial) model structure in which a map is a weak equivalence (resp. a fibration) if it is objectwise a weak equivalence (resp. fibration). Moreover, this model structure is left proper if $C$ is left proper and is simplicial if $C$ is simplicial.

Proof. This proposition has nothing to do with $\Psi$ and would be true for any functor category with a small source.

The existence of the model structure in the combinatorial case is very classical. If $C$ is cocombinatorial, then $C^{\text{op}}$ is combinatorial. Therefore, $\text{Fun}(\Psi, C^{\text{op}})$ admits the injective model structure by [Lur09, Proposition A.2.8.2.] which dualizes to the projective model structure on $\text{Fun}(\Psi^{\text{op}}, C) = \text{POpC}$.

The left properness follows from [Lur09, Remark A.2.8.4.]

The simplicialness of $\text{POpC}$ follows from [Lur09, Proposition A.3.3.2.]. In the combinatorial case, we need to dualize but this is not a problem since the opposite of a simplicial model category is a simplicial model category. □

Assume that we have an adjunction
$$A : C \rightleftarrows D : B$$
then, by applying $A$ and $B$ levelwise, we get an adjunction
$$A : \text{POpC} \rightleftarrows \text{POpD} : B$$
For future references we have the following very easy proposition:

A.9. Proposition. If $(A, B)$ is a Quillen adjunction, then the adjunction
$$A : \text{POpC} \rightleftarrows \text{POpD} : B$$
is a Quillen adjunction.

The weak operads model structure. Let $C$ be a model category such that $\text{POpC}$ can be given the projective model structure. According to proposition A.8, this happens for instance if $C$ is combinatorial or cocombinatorial.

For $X$ an object of $\text{POpC}$ and $F : \Psi^{\text{op}} \to \text{Set}$ a presheaf, we denote by $X(F)$ the object of $C$ computed via the following end
$$X(F) = \int_{T_a \in \Psi} X(T_a)^{F(T_a)}$$
Alternatively, $F \mapsto X(F)$ is the unique colimit preserving functor $\text{Fun}(\Psi^{\text{op}}, \text{Set}) \to C$ sending $\Psi(-, T_a)$ to $X(T_a)$. For $S$ a set and $K$ an element of $C$, we denote by $S \boxtimes K$ the coproduct $\sqcup_i K$.

For $F$ a presheaf on $\Psi$ and $K$ an element of $C$, we denote by $K \boxtimes F$ the presheaf with value in $C$ given by $T_a \mapsto K \boxtimes X(T_a)$. We note that $K \boxtimes F$ is the object of $\text{Fun}(\Psi^{\text{op}}, C)$ representing the functor $X \mapsto C(K, X(F))$.

Given $a = \{a_1, \ldots, a_n\}$ an object in the category $\Psi$, there is an isomorphism
$$\bigsqcup_i T_{a_i} \cong T_a$$
Thus, for any preoperad $X$ in $C$, we get a map
$$s_{a, X} : X(a) \to \prod_i X(a_i)$$
that we call the Segal map.
A.10. **Definition.** We say that a fibrant object $X$ of $\text{POpC}$ is a *weak operad*, if for any $T_a$ in $\Psi$, the Segal maps
\[ s_{a,X} : X(T_a) \to \prod_X a_i \]
are weak equivalences. We say that a general object $X$ of $\text{POpC}$ is a weak operad if one (and hence any) fibrant replacement of $X$ is a weak operad.

Now we assume that $C$ is left proper and either combinatorial or cocombinatorial.

A.11. **Proposition.** There is a model structure on $\text{POpC}$ in which
- The cofibrations are the cofibrations of $\text{POpC}$.
- The fibrant objects are the weak operads that are fibrant in $\text{POpC}$.
- The weak equivalences are the maps $f : X \to Y$ such that for any weak operad $Z$, the induced map
  \[ \text{Map}_{\text{POpC}}(Y, Z) \to \prod \text{Map}_{\text{POpC}}(X, Z) \]
is a weak equivalence.

*Proof.* In the combinatorial case, we can use theorem 1.9. We need to specify a set of maps $S$ such that the $S$-local object are the weak operads. Let $\kappa$ be a regular cardinal such that $C$ is $\kappa$-presentable and such that the $\kappa$-filtered colimits are homotopy colimits (it exists by [Bar10, Proposition 2.5.]). Let $\mathcal{G}$ be a set of objects containing at least one representative of each isomorphism class of $\kappa$-compact object of $C$. Let $Q$ be a cofibrant replacement functor in $C$.

Let us consider the set $S$ of maps
\[ \bigsqcup \Psi(-, T_a) \boxtimes QK \to \Psi(-, T_a) \boxtimes QK \]
for any $a$ and any $K$ in $\mathcal{G}$.

We claim that a fibrant object $X$ of $\text{POpC}$ is a weak operad if and only if it is local with respect to $S$. Indeed, an object $X$ is $S$-local if and only if for each $a$ and any $K$, the map
\[ \text{Map}_{C}(K, X(T_a)) \to \prod X(T_a) \]
is a weak equivalence. Thus, if $X$ is a weak operad, it is $S$-local. Conversely, Let $L$ be an object of $C$. Since $\kappa$-filtered colimits are homotopy colimits, $L$ is weakly equivalent to $\text{hocolim}\ K_i$ where the $K_i$ are in $\mathcal{G}$ and $I$ is $\kappa$-filtered. Therefore, using the fact that $X$ is fibrant, we find that
\[ \text{Map}_{C}(L, X(T_a)) \to \prod X(T_a) \]
is a weak equivalence. Since this is true for each $L$, this implies that the Segal maps for $X$ are weak equivalences.

In the cocombinatorial case, we use theorem 1.10 to prove the existence of the model structure. We take as $\mathcal{K}$, the full subcategory of weak operads in $C$. It is clear that $\mathcal{K}$ is stable under weak equivalences and homotopy limits. Thus it suffices to prove that $\mathcal{K}$ is coaccessible and coaccessibly embedded.

By proposition A.8 $\text{POpC}$ is cocombinatorial. Therefore, by [Bar10, Proposition 2.5.], there exists a cardinal $\kappa$ such that $\kappa$-cofiltered limits are homotopy limits, the limit of a $\kappa$-cofiltered diagram in $\mathcal{K}$ is in $\mathcal{K}$ and thus is the limit in $\mathcal{K}$. Therefore $\mathcal{K}$ has $\kappa$-cofiltered limits and the inclusion $\mathcal{K} \to \text{POpC}$ preserves those limits.
Now we check that $\mathcal{K}$ is coaccessible. Let us pick a $\kappa$-coaccessible fibrant replacement functor $R$. This can be done by [Bar10, Proposition 2.5]. We have a map

$$P : \mathbf{POpC} \to \prod_{T_a \in \Psi} \mathbb{C}^{[1]}$$

whose component indexed by $T_a$ sends $X$ to the map

$$s_{a,RX} : RX(T_a) \to \prod_i RX(R_{a_i})$$

By definition, a weak operad is an object which is in the inverse image of the category $\prod_{T_a \in \Psi} w\mathbb{C}^{[1]} \subset \prod_{T_a \in \Psi} \mathbb{C}^{[1]}$.

Taking maybe a bigger $\kappa$, the category $\prod_{T_a \in \Psi} w\mathbb{C}^{[1]}$ is $\kappa$-coaccessible and $\kappa$-coaccessibly embedded in $\prod_{T_a \in \Psi} \mathbb{C}^{[1]}$, thus by [Lur09, Corollary A.2.6.5], $\mathcal{K}$ forms a $\kappa$-coaccessible category.

**Operads vs weak operads in spaces.** The category of operads in spaces admits a model structure in which the weak equivalences and fibrations are levelwise. This follows from [BM03, Theorem 3.1.] or the more general [Ber06, Theorem 4.7.]. The operadic nerve functor from operads in spaces to preoperads has a left adjoint $S$. Since $\mathbf{OpS}$ is a simplicial category with all colimits and $\mathbf{POpS}$ is a presheaf category, there exists a unique colimit preserving simplicial functor $S$ from $\mathbf{POpS}$ to $\mathbf{OpS}$ that sends the object represented by $T_a$ to $F_a$. It is then obvious that this $S$ is a left adjoint for $N^\Psi$.

The adjunction

$$S : \mathbf{POpS} \rightleftarrows \mathbf{OpS} : N^\Psi$$

is a simplicial Quillen adjunction. Indeed, the functor $N^\Psi$ obviously preserves fibrations and trivial fibrations. If $f : X \to Y$ is a weak equivalence in $\mathbf{WOpS}$, then, for any fibrant object $\mathcal{O}$ in $\mathbf{OpS}$, the map

$$\text{Map}^h_{\mathbf{OpS}}(LSY, \mathcal{O}) \to \text{Map}^h_{\mathbf{OpS}}(LSX, \mathcal{O})$$

induced by $f$ coincides by theorem 1.3 with the map

$$\text{Map}^h_{\mathbf{POpS}}(Y, N^\Psi \mathcal{O}) \to \text{Map}^h_{\mathbf{POpS}}(X, N^\Psi \mathcal{O})$$

Thus since $N^\Psi \mathcal{O}$ is a weak operad, we see that if $f$ is a weak equivalence in $\mathbf{WOpS}$, then $LS(f)$ is one in $\mathbf{OpS}$. This implies that we have an induced Quillen adjunction

$$S : \mathbf{WOpS} \rightleftarrows \mathbf{OpS} : N^\Psi$$

**A.12. Theorem.** The Quillen pair $(S, N^\Psi)$ is in fact a Quillen equivalence

**Proof.** This is [Ber06, Theorem 5.13.]

**Operads vs weak operads in groupoids.** Our goal in this subsection is to prove that the homotopy theory of weak operads in groupoids is equivalent to the homotopy theory of strict operads.

We have an adjunction

$$S : \mathbf{POpG} \rightleftarrows \mathbf{OpG} : N^\Psi$$

As in the case of spaces, we construct $S$ as the unique $G$-enriched functor which sends the presheaf represented by $T_a$ to $F_a$ seen as an operad in $G$ via the product preserving functor $\text{Disc} : \mathbf{Set} \to G$.

Exactly as in the case of spaces, it induces a Quillen adjunction

$$S : \mathbf{WOpG} \rightleftarrows \mathbf{OpG} : N^\Psi$$

**A.13. Proposition.** This Quillen adjunction is a Quillen equivalence.
Proof. Let $S_{\leq 1}$ be the localization of $S$ at the map $\partial \Delta[2] \to \Delta[2]$. The model category $S_{\leq 1}$ being combinatorial, we can form the model category $WOpS_{\leq 1}$. The cofibrations in this model structure are the cofibrations of $WOpS$ and the fibrant objects are the weak operads in $S$ that are levelwise fibrant in $S_{\leq 1}$.

We can also form the model category $OpS_{\leq 1}$. This is a model category in which the cofibrations are the cofibrations in $OpS$ and the fibrant objects are the operads that are levelwise in $S_{\leq 1}$. The existence of this model structure follows from [BM03, Theorem 3.1.]. A symmetric monoidal fibrant replacement functor in $S_{\leq 1}$ is given by $X \mapsto B\pi(X)$.

We have a Quillen adjunction. $S : WOpS_{\leq 1} \leftrightarrows OpS_{\leq 1} : N^\psi$

We claim that this is a Quillen equivalence. If $O$ is a fibrant object of $OpS_{\leq 1}$, then the counit map $SQN^\psi O \to O$ is a weak equivalence in $OpS$. This follows from the fact that the cofibrant replacement in $OpS_{\leq 1}$ is a cofibrant replacement in $OpS$ and the fact that the adjunction $WOpS \leftrightarrows OpS$ is a Quillen equivalence.

Similarly, let $X$ be cofibrant in $WOpS_{\leq 1}$. Let $RSX$ be a fibrant replacement of $SX$ in $OpS$. Let $R_1SX$ be a fibrant replacement of $RSX$ in $OpS_{\leq 1}$. We have a map $RSX \to R_1SX$ which is in each degree a weak equivalence in $S_{\leq 1}$. Applying $N^\psi$, we get a weak equivalence in $WOpS_{\leq 1}$:

$$N^\psi RSX \to N^\psi R_1SX$$

Since we already know by theorem A.12 that $X \to N^\psi RSX$ is a weak equivalence in $WOpS$, we have shown that the derived unit

$$X \to N^\psi R_1SX$$

is a weak equivalence in $WOpS_{\leq 1}$.

We also have a Quillen equivalence $\pi : S_{\leq 1} \leftrightarrows G : B$ whose right adjoint is the classifying space functor. This induces a commutative square of left Quillen functors

$$\begin{array}{ccc}
WOpS_{\leq 1} & \xrightarrow{S} & OpS_{\leq 1} \\
\pi \downarrow & & \downarrow \pi \\
WOpG & \xrightarrow{S} & OpG
\end{array}$$

We know that all maps except maybe the bottom horizontal map are Quillen equivalences. This forces the bottom horizontal map to be a Quillen equivalence.

We can also prove that the functor $B : WOpG \to WOpS$ is homotopically fully faithful.

A.14. Proposition. Let $X$ and $Y$ be two fibrant object of $WOpG$, then the map

$$\Map^h_{WOpG}(X, Y) \to \Map^h_{WOpS}(BX, BY)$$

is a weak equivalence.

Proof. According to the previous proposition, we have a sequence of Quillen adjunctions

$$WOpS \leftrightarrows WOpS_{\leq 1} \leftrightarrows WOpG$$

where the first is a localization and the second is an equivalence.

Thus we are reduced to proving that

$$\Map^h_{WOpS_{\leq 1}}(BX, BY) \to \Map^h_{WOpS}(BX, BY)$$

is a weak equivalence which is true by definition of a Bousfield localization since $BX$ and $BY$ are fibrant in $S_{\leq 1}$.
