ABSTRACT

Some electrodes for efficient detection of paracetamol and dopamine were developed from nano sized material of cobalt ferrite (np-CoFe₂O₄) and manganese ferrite (np-MnFe₂O₄). These oxides were synthesized by combustion method using cobalt nitrate, manganese acetate and ferric nitrate as precursors in the presence of sugar and ethanolamine. The crystallite size, shape and morphology of nano material were characterized by X-ray diffraction pattern (XRD), field emission scanning electron microscopy (FESEM) and energy-dispersive X-ray spectroscopy (EDS) techniques. The crystallite sizes of synthesized nano-particles (nps) were in the range from 10 to 12 nm (calculated using Debye-Scherrer equation) with cubic crystal system. These particles were utilized as electrode modified with graphite for simultaneous detection of paracetamol and dopamine through cyclic voltammetry and Differential pulse voltammetry techniques and was found to be superior to reported literatures. The minimum detection limit of paracetamol and dopamine at CoFe₂O₄/GP electrode were 250 nM and 350 nM while at MnFe₂O₄/GP electrode it was 300 nM and 400 nM, respectively. Both the electrodes exhibited the linearity range from 3 μM to 200 μM & 3 μM–160 μM for paracetamol and 3 μM–180 μM & 5 μM to 200 for dopamine, respectively. Two oxidation peaks of paracetamol and dopamine were well separated in phosphate buffer (pH = 6) in mixture with 100 mVs⁻¹ and 50 mVs⁻¹ scan rate for cyclic voltammetry and Differential pulse voltammetry, respectively. Both the electrodes demonstrated satisfactory results in real samples of paracetamol and dopamine.

1. Introduction

For detection of drug molecules in bio-fluids, the drug monitoring is essential and can play an important role in drug quality control. Paracetamol (acetaminophen-N-acetyl-p-aminophenol, PCM), a well known antipyretic & analgesic compound is extensively used for the treatment of fever, cough & cold, pain including muscular ache, chronic pain, migraine, headache, backache and toothache [1, 2, 3]. PCM offers some protection against ovarian cancer [4] when the therapeutic doses are administered, without any harmful side effect but the overdose and the chronic use of PCM produces toxic metabolite accumulation which may result in kidney & liver failure or even death [5, 6, 7, 8].

Dopamine (4-(2-aminoethyle) benzene-1,2-diol, DA), a naturally occurring biogenic compound, known for its inhibitory neurotransmitter, is produced in the “Dargic neurons” in the ventral tegmental area (VTA) of the mid brain, strongly associated with reward mechanisms in the brain like memory, locomotion, learning and behavior of cognition. As a hormone, it mediates not only the functioning of central and peripheral nervous system [9, 10] during physical activities but also is responsible for emotion and endocrine system. Low concentration of DA may lead to burning mouth syndrome [11], restless leg syndrome [12], Senile dementia, fibromyalgia [13, 14] and rarely depression [15]. Depletion of DA in cerebral region may lead to Parkinson's disease [16] while high concentration of DA, due to addiction of cocaine, heroin, nicotine, alcohol and long term smoking etc., may act on sympathetic nervous system and cause abnormal blood pressure and an incensement in heart rate. A large number of analytical techniques like titremetry [1], high performance liquid chromatography [17, 18, 19], spectrophotometry [20], chemiluminescence [21], gas-chromatography-mass spectrometry [22] and ultraviolet spectrophotometry [23] have been developed for the detection of PCM and DA in biological fluids and tablets. But these techniques are not convenient for routine analysis due to their tedious extraction process. Recently developed electrochemical techniques [24,
25, 26, 27, 28, 29, 30] have received tremendous attention for the detection of PCM and DA in biofluids, due to their high selectivity, low cost, easy handling and less time consuming nature. Literature review reveals that nano materials with porous morphology having high surface area were conventionally used for electrode material for the detection of bio-molecules as well as drug molecules [31, 32, 33]. Various electrodes have been developed for detection of these molecules. The developed electrodes are gold nano particles for PCM [34], multi-walled carbon nano-tubes for PCM [35], nitrogen doped porous graphitic carbon for the detection of PCM [36], MWCNTs modified carbon paste electrode for DA [37], multi-walled carbon nano-tubes/graphene oxide nano-composite-modified glassy carbon electrode for DA and PCM [38], activated graphene-Nafion modified glassy carbon electrode for DA and acetaminophen [39], carbon paste electrode modified with 4-porphyrin for the simultaneous quantification of DA, acetaminophen-3 and tyrosine [40], glassy carbon electrode modified with a nano-composite consisting of nanoporous platinum-yttrium and graphene for DA [41], graphene ink film for PCM [47], F.D. Saccone synthesized CoFe$_2$O$_4$ nano particles by co-precipitation method using NaOH, but not used for electrochemical detection [42]. Zeid Abdullah Alothman et al. developed acid functionalized multi-wall carbon nano-tubes (f-MWCNTs) modified glassy carbon electrodes for the simultaneous determination of DA & PCM [43], G. P. Keeley et al. developed a sensor for simultaneous electrochemical determination of DA and PCM based on thin pyrolytic carbon films [44], Q Wan et al. developed MWNT-film coated electrodes for voltammetric detection of acetaminophen [45], S.F. Wang et al. developed Carbon-coated nickel magnetic nano-particles modified electrodes as a sensor for determination of acetaminophen [25], L. Fu et al. Graphene Ink Film Based Electrochemical Detector for Paracetamol [46].

No report is available on detection of PCM and DA simultaneously using npCoFe$_2$O$_4$/GP or np-MnFe$_2$O$_4$/GP electrodes. Herein we report cheaper and effective electrodes from np-CoFe$_2$O$_4$ and np-MnFe$_2$O$_4$ modified with graphite for the detection of PCM & DA. Both modified electrodes (np-CoFe$_2$O$_4$/GP & np-MnFe$_2$O$_4$/GP) have superior electrocatalytic activities for oxidation of PCM & DA separately as well as in

### Table 1
Lattice parameters for the synthesized Manganese ferrite and Cobalt ferrite nano particles.

| S.No | Standard values of a (Å) | Calculated value of a (Å) | Deviation | h  | k  | l  |
|------|--------------------------|---------------------------|-----------|----|----|----|
| 1    | 9.4000                   | 9.4000                    | 0.0000    | 2  | 2  | 2  |
| 2    | 9.4000                   | 9.3999                    | 0.0001    | 0  | 4  | 4  |
| 3    | 9.4000                   | 9.3999                    | 0.0001    | 2  | 2  | 6  |

| S.No | Standard values of a (Å) | Calculated value of a (Å) | Deviation | h  | k  | l  |
|------|--------------------------|---------------------------|-----------|----|----|----|
| 1    | 8.3410                   | 8.3410                    | 0.0000    | 1  | 1  | 3  |
| 2    | 8.3410                   | 8.3410                    | 0.0000    | 1  | 1  | 5  |
| 3    | 8.3410                   | 8.3409                    | 0.0001    | 0  | 4  | 4  |

*The systems are cubic so lattice parameters are equal (a = b = c). The values of “a” are calculated from stronger peaks of XRD.
the mixture with good selectivity, high sensitivity and better repeatability. These electrodes also displayed efficient performance for real samples of commercially available PCM.

2. Experimental

2.1. Chemicals and reagents

Manganese acetate [Mn(CH$_3$COO)$_2$], Cobalt nitrate (Co(N-O$_3$)$_2$·6H$_2$O), Monoethanolamine (C$_2$H$_7$NO), Nitric Acid (HNO$_3$), sugar and Paraffin oil were purchased from Merck, India, graphite flakes was obtained from Sigma Aldrich, USA. All the reagents were of analytical grade and used without further purification. Double distilled water was used for preparation of all the solutions.

2.2. Synthesis of nanoparticles

To the aq. solution of manganese acetate (0.01 mol) and Ferric nitrate (0.02 mol), added monoethanolamine (0.25 mol) and sugar (0.17 mol) followed by addition of HNO$_3$ (0.44 mol) with constant stirring. The

Fig. 3. FESEM image of (a) MnFe$_2$O$_4$ (c) CoFe$_2$O$_4$ and EDS image of (b) MnFe$_2$O$_4$ and (d) CoFe$_2$O$_4$ nps, TEM image of synthesized particles (e) for MnFe$_2$O$_4$ (f) for CoFe$_2$O$_4$ and inset of Fig. 3 (e) and (f) represents particle size distribution graphs of MnFe$_2$O$_4$ and CoFe$_2$O$_4$ respectively.

Fig. 4. Cyclic Voltammogram obtained for 3.0 mM Fe(CN)$_6^{3-}$/Co$_4^{4+}$ at CoFe$_2$O$_4$/GP, MnFe$_2$O$_4$/GP and bare GP electrodes at 100 mVsec$^{-1}$ scan rate with phosphate buffer solution of pH 6.0.
mixture was then boiled on a hot plate until a black fluffy mass was obtained. Further, this fluffy mass was calcined in muffle furnace at 600 °C for about 6–7 h to obtain the nanoparticles of MnFe₂O₄. We also adopted similar procedure by taking cobalt nitrate (0.01 mol) and ferric nitrate (0.02 mol), as a precursor material for the synthesis of CoFe₂O₄ nanoparticles (Fig. 1a).

2.3. Preparation of electrode

Synthesized np-MnFe₂O₄ and graphite powder in 1:4 (w/w) ratio were grinded along with 2–3 drop paraffin oil. The final paste was transferred into the capillary glass tube (2 mm inner diameter, 0.031 cm² geometrical surface area) and compressed with a metal rod. From the back side of the electrode, Scheme 1. Suggest oxidation mechanism for analyte molecule at prepared electrode.

![Scheme 1](image)

**Fig. 5.** Scan rate of 0.1 mM (a) DA varied at CoFe₂O₄/GP (b) PCM varied at CoFe₂O₄/GP electrode (c) DA varied at MnFe₂O₄/GP (d) PCM varied at MnFe₂O₄/GP electrode.
capillary tube, a Pt-wire was attached for electrical contact. Similar procedure was applied for the preparation of bare graphite paste electrode. 0.3 mM and 0.05 mM Al₂O₃ slurry was used to clean the surface of the electrodes. The electrodes were rinsed with ethanol and dried under N₂ atmosphere before experiments. Similar procedure was used for the preparation of CoFe₂O₄/GP electrode (Fig. 1b).

2.4. Apparatus and measurements

The crystallite size of synthesized nano material were determined by X-ray diffraction (XRD) patterns by Panalytical X-ray diffractometer, model no. X’PertPRO (Neetherlands) with Cu K-alpha radiation (λ = 1.5406Å). The morphology, shape, size and elemental composition of synthesized nano-particles were determined by Hitachi field emission scanning electron microscopy (FESEM), model no. SU8010 along with Bruker’s energy-dispersive X-ray spectroscopy detector (EDS) model is XFlash 6130. TEM analysis was performed by FEI Tecnai G2 30 S-TWIN Model TEM microscope. All the electrochemical measurements were performed using AUTOLAB potentiostate/Galvanostate 101 (Netherlands) with three electrode system including a platinum electrode as a counter electrode and Ag/AgCl electrode as a reference electrode. All the electrochemical studies were carried out in 0.1(M) phosphate buffer of pH 6.0 at 25±2 °C using Cyclic voltammetry (CV) and Differential pulse voltammetry (DPV) techniques. All the CV measurements were carried out at a scan rate 100 mVs⁻¹ but for DPV scan rate was maintained at 50 mV s⁻¹. DPV measurements were carried out with 5 mV step potential, 40 mV modulation amplitude, 0.02 s modulation times and 0.1 s interval time. The voltage ranges for the oxidation of DA and PCM in CV experiments were 0.25 V–0.35 V and 0.55V to 0.65 V, respectively. For DPV experiments with DA and PCM, voltage ranges were from 0.22 V to 0.3 V and 0.42 V–0.60 V, respectively.

3. Results and discussion

3.1. XRD analysis of MnFe₂O₄ &CoFe₂O₄ nano-particles

XRD technique is used to get information about crystal structure and phase purity of the synthesized nano materials. Diffraction lines of XRD pattern were in good agreement with standard ICSD card No. 98-007-7782 for CoFe₂O₄ and ICSD card No. 98-001-7884 for MnFe₂O₄. The crystallite size of synthesized np-MnFe₂O₄ and np-CoFe₂O₄ were calculated using ‘Debye–Scherrer method’ (D = Kλ/β cos θ), where D is average crystallite size, β is full width at half maxima (FWHM), λ is wavelength of X-rays (λ = 1.5406Å), θ is diffraction angle, and k is a constant value which depends on several factors including the Miller index [47] with selecting the 100% intensity peak with hkl value 113 for CoFe₂O₄ nps and also 100 % intensity peak with hkl value 222 for MnFe₂O₄ nps (see hkl value 113 in Fig. 2a and hkl value 222 in Fig. 2b.) The calculated crystallite sizes (D) of np-manganese ferrite and np-cobalt ferrite were found to be in ranges from 7 to 10 nm and 9–12 nm, respectively with cubic crystal system (Fig. 2). The lattice parameters are calculated and presented in Table 1.

3.2. FESEM, EDS and TEM analysis of CoFe₂O₄ & MnFe₂O₄ nano particles

The field emission scanning electron microscopy (FESEM) technique was used to study the surface morphologies of synthesized cobalt ferrite
Table 2
Electrocatalytic oxidation of individual and binary mixture of bio-molecules (PCM and DA) at CoFe2O4/GP and bare GP electrodes by using cyclic voltammetry at scan rate 100 mV/s.

| Electrodes  | Concentration (μM) | Anodic peak potential (mV) | Oxidation peak current (μA) |
|-------------|---------------------|---------------------------|---------------------------|
|             | PCM     | DA     | PCM | DA     | PCM | DA |
| CoFe2O4/GP  | 100     | 0      | 597 | -      | 11.73 |       |
| GP          | 100     | 0      | 610 | -      | 5.24  |
| CoFe2O4/GP  | 0       | 100    | -   | 337    | -     | 14.52 |
| GP          | 0       | 100    | -   | 453    | -     | 3.04  |
| CoFe2O4/GP  | 50      | 50     | 673 | 431    | 9.16  | 7.91  |

(np-CoFe2O4) and manganese ferrite (np-MnFe2O4). Fig. 3 illustrates that the particles have uniform cubic structural morphology with narrow size distribution. The EDS image of synthesized nano-particles Fig. 3(b) and 3(d) show that nano-particles had no impurities. The TEM studies (Fig. 3(e) and 3(f) of synthesized nano materials (cobalt ferrite and manganese ferrite) also supported the FESEM results.

3.3. Electrochemical studies of MnFe2O4/GP and CoFe2O4/GP electrodes

Electrochemical properties of prepared MnFe2O4/GP electrode, CoFe2O4/GP electrode and bare GP electrodes were studied by using standard redox system \([\text{Fe(CN)}_6^{3-}/\text{Fe(CN)}_6^{4-}]\) as reference. The comparative cyclic voltammograms of 3 mM \(K_4[\text{Fe(CN)}_6]\) solution at bare GP, MnFe2O4/GP and CoFe2O4/GP electrodes are represented in Fig. 4. In this study, approximately two protons were transferred in the reaction. Paracetamol oxidation is a two-electron and two-proton process (Scheme 1) [48].

Some parameters like particle size, surface defects, electrochemical band gap, composition, optical band gap & capping ligand play important roles in the voltammetric response of the semiconducting materials [49, 50, 51, 52, 53]. For these reasons nano-particles are very relevant for electro-chemical analysis. From Fig. 4 it was noted that the peak potential separation (ΔEp) at MnFe2O4/GP and CoFe2O4/GP electrodes were 156 mV and 116 mV, respectively whereas at bare GP electrode it was 185 mV. According to Velasco equation the low value of ΔEp indicates the faster electron transfer between the electrode surface and analyte molecules. From the comparison of ΔEp of prepared electrodes, it can be concluded that np-MnFe2O4/GP and np-CoFe2O4/GP electrodes are efficient for electron transfer than bare GP. As per cyclic voltammetric response for DA, the oxidation peak currents at CoFe2O4/GP and MnFe2O4/GP were found to be 4.58 and 2.27 times higher with respect to bare GP. For PCM oxidation peak current was about 4.5 times higher with respect to bare GP at CoFe2O4/GP electrode. The peak separations of detecting molecules (one peak for DA and another for PCM) had been found to be 220 mV and 216 mV at CoFe2O4/GP electrode and MnFe2O4/GP electrode, respectively.
3.4. Effect of the scan rate and pH on the oxidation of DA & PCM

Effects of scan rates towards the electrocatalytic oxidation of DA and PCM were investigated with the scan rates from 5 mVs⁻¹ to 500 mVs⁻¹ in CV technique. It was noted that there was a linear increment in the peak current for both the molecules with increase of scan rate. Fig. 5 indicates the oxidation process was diffusion controlled at the surface of electrodes. The pH of supporting electrolyte plays a key role for the electrochemical oxidation of molecules. To study the effect of pH on the oxidation of DA and PCM, 0.1 M phosphate buffer solution (PBS) were used having pH range from 5.0 to 7.0. The peak currents of DA and PCM increased with increasing the pH up to 6.0 and then decreased with further increase of pH value. The maximum peak current value at npXFe₂O₄/GP (where X is Co/Mn) was observed at pH 6.0. The results are shown in Fig. 6. So PBS of pH 6.0 was used for all experimental works.

3.5. Electrocatalytic oxidation of PCM and DA at npCoFe₂O₄/GP and npMnFe₂O₄/GP electrodes

Electro-catalytic behavior of modified electrodes had been studied in CV and DPV techniques for individual molecule and mixture. The results of np-MnFe₂O₄/GP electrode, np-CoFe₂O₄/GP electrode and bare GP electrode are shown in Fig. 6. Electrochemical measurement parameters are summarized in Table 2. The cyclic voltammogram of individual PCM molecule at bare GP electrode, np-MnFe₂O₄/GP electrode and np-CoFe₂O₄/GP electrodes are also shown in Fig. 7(a) and for DA in Fig. 7(b). Both the molecules (PCM & DA) followed irreversible oxidation characters at all the electrodes. For DA, oxidation peak potential at bare GP electrode was 365 mV while atMnFe₂O₄/GP and CoFe₂O₄/GP electrodes, oxidation peak potential were 345 mV and 342 mV, respectively. For PCM oxidation peak potential at bare GP was 613 mV while atMnFe₂O₄/GP and CoFe₂O₄/GP electrodes the oxidation peak potential was 567 mV and 602 mV, respectively. The electrodes np-MnFe₂O₄/GP and np-CoFe₂O₄/GPacted as efficient sensors for both the molecules. Fig.7(c) and 7(d) present well separated DPV plots of binary mixture of DA and PCM molecules. At CoFe₂O₄/GP electrode, oxidation peak for PCM appeared at 470 mV and for DA, it appeared at 250 mV and separation is 220 mV. While at MnFe₂O₄/GP electrode oxidation peak for PCM appeared at 480 mV and for DA, it appeared at 264 mV with the separation 216 mV.

3.6. Simultaneous determination of PCM & DA

For the simultaneous determination of DA & PCM molecules in the mixture was verified by CV technique maintaining voltage range from 0.2 V to 0.85 V with the scan rate 100 mV/s. For better resolution and higher peak current, differential Pulse Voltammetry (DPV) was preferred. A controlled DPV experiment had been carried out at CoFe₂O₄/GP electrode, keeping concentration of PCM (100 μM) fixed, with variable concentration of DA from 3 to 180 μM (Fig. 8a). The first linear range were observed from 30 to 80 μM having corresponding regression equation IDA

$$y = 0.000 + 0.021 R^2 = 0.978$$

and second linear range was from 80 to 180 μM.
μM having corresponding regression equation IDA $y = 0.001 - 0.069$, $R^2 = 0.988$. Similar experiment had been carried out keeping concentration of DA (100 μM) fixed with variable concentration of PCM from 3 to 200 μM (Fig. 8b). The first linear range was observed from 3 to 80 μM with corresponding regression equation $IPCM \ y = 0.07 + 0.946$, $R^2 = 0.978$ and second linear range was observed from 80 to 200 μM with corresponding regression equation $IPCM \ y = 0.002 + 0.172$, $R^2 = 0.989$. At CoFe2O4/GP electrode two linear ranges were observed. The first linear range might have appeared due to adsorption of DA/PCM molecule on the surface of the sensor electrode, while second linear range might be due to diffusion processes on the monolayer covered surface [54].

The similar experiment at MnFe2O4/GP electrode had been performed keeping concentration of PCM (100 μM) fixed with variable concentration of DA from 5 to 200 μM and observed linearity range from 5 to 200 μM with corresponding regression equation $y = 0.003DA + 0.049$ $R^2 = 0.99$ (Fig. 8c). Keeping concentration of DA (100 μM) fixed, in similar experiment, with variable concentration of PCM from 3 to 160 μM, it was observed linearity from 3 to 160 μM with corresponding regression equation $y = 0.001PCM + 0.065$ $R^2 = 0.961$ (Fig. 8d).

At npCoFe2O4/GP electrode, the minimum detection limit was observed 250 nM and 350 nM for PCM and DA respectively and at npMnFe2O4/GP electrodes it was 300 nM and 400 nM, respectively for above molecules.

3.7. Comparative study of different synthesized modified electrodes with present electrodes

On the basis of comparison (Table 3), it may be concluded that the newly developed np-manganese ferrite and np-cobalt ferrite modified graphite paste electrode are superior to previous reports in sensitivity i.e. linearity range and minimum detection limit.

3.8. Repeatability, stability and reproducibility of electrodes

To check stability of the modified electrodes (XFe2O4/GP, where $X = Co$ & $Mn$), electrodes were stored at 30 °C ± 1 °C for 90 days and observed 97% retention of sensing response indicating good stability of the electrodes. The electrode responses were noted for 15 consecutive measurements and were found to have similar performance indicating good reproducibility. To check reproducibility, five electrodes were prepared. All five electrodes showed similar results supporting good reproducibility. All the experiments concluded that the reproducibility, repeatability and stability of the electrode were excellent.

| Modified Electrode | detection limit (nM) | Liner range (μM) | Ref. |
|--------------------|----------------------|------------------|------|
| f-MWCNT            | 600                  | 3–300            | 3–200| [43] |
| Pyrolytic carbon   | 1400                 | 15–225           | 18–270| [44] |

Table 3
Comparison of sensitivity of manganese-ferrite and cobalt ferrite modified graphite paste electrodes with other previously developed electrodes.
4. Conclusion

Mn and Co) electrodes have good efficiency for the analysis of PCM & DA in real samples. From the results it may be concluded that the np-XFe2O4/GP (where X = M, respectively at np-CoFe2O4/GP electrode and 0.30 μM and 0.35 μM, respectively with respect to standard sample. The collection of urine sample was done after 5 h of PCM dose. It was diluted with phosphate buffer solution (0.1M) of pH 6. The results are summarized in Table 4. From the results it may be concluded that the np-XFe2O4/GP (where X = Mn and Co) electrodes have good efficiency for the analysis of PCM & DA in real samples.

3.9. Real sample analysis

The performance of the modified electrodes was checked using real samples of drug molecules using urine, PCM tablets & injections. The recovery values for PCM in tablet and injection were 98.3%, 99.7% respectively at np-MnFe2O4/GP electrode.

| Electrode Sample | Original/Diluted sample (μM) | Spiking (μM) | Found (μM) | R.S.D. (%) | Recovery (%) |
|------------------|-----------------------------|-------------|------------|------------|--------------|
| Urine Sample     |                             |             |            |            |              |
| DA               | 20                          | 30          | 50.5       | 1.92       | 101.5        |

(Fig. 9).

4. Conclusion

Nano particles of CoFe2O4 and MnFe2O4 were synthesized using combustion technique having crystallite size of 10–12 nm. The synthesized nano-particle based electrodes demonstrated excellent sensitivity in detecting drug/bio molecules (PCM and DA) in biological fluids and commercial samples with the minimum detection limit 0.25 μM and 0.35 μM, respectively at np-CoFe2O4/GP electrode and 0.30 μM and 0.40 μM, respectively at np-MnFe2O4/JP electrode.
