A HODGE FILTRATION OF LOGARITHMIC VECTOR FIELDS
FOR WELL-GENERATED COMPLEX REFLECTION GROUPS

TAKURO ABE, GERHARD RÖHRLE, CHRISTIAN STUMP, AND MASAHIKO YOSHINAGA

Abstract. Given an irreducible well-generated complex reflection group, we construct an explicit basis for the module of vector fields with logarithmic poles along its reflection arrangement. This construction yields in particular a Hodge filtration of that module. Our approach is based on a detailed analysis of a flat connection applied to the primitive vector field. This generalizes and unifies analogous results for real reflection groups.

1. Introduction

The study of vector fields with logarithmic poles along the reflection arrangement of a finite Coxeter group inside a real vector space has been a particularly active and fruitful area of recent research. Most importantly, Abe-Terao use Saito’s primitive derivation to construct an explicit basis of this vector field in [AT10], thereby extending Saito’s Hodge filtration of invariant polynomial derivations to a Hodge filtration of the module of invariant vector fields with logarithmic poles. Also, Wakamiko identified the concept of a universal vector field as a crucial ingredient in his construction of an explicit basis in [Wak11, Sec. 2].

Based on a recent extension of Saito’s primitive derivation and Hodge filtration to well-generated unitary reflection groups in [HMRS19], we establish analogues of the above constructions in this more general setting. Specifically, we provide a framework to extend [AT10, Thms. 1.1 & 1.2] to well-generated unitary reflection groups (Theorem 4.2 and Corollary 4.3), and derive universality results generalizing [Wak11, Sec. 2] (Theorems 4.17, 4.19 and 4.22). Because of the new explicit form of the flat connection in [HMRS19], the approach we provide here has not appeared in the literature even in the real case, simplifying several arguments.

We give a brief comment on the terminology of a “Hodge filtration” in our context. This was introduced by K. Saito in [Sai83]. The primitive form is a special element in the relative de Rham cohomology group for the deformation of an isolated hypersurface singularity, which satisfies lots of nice properties. For simple singularities of type ADE, the parameter space of the deformation is identified with the quotient of the Cartan subalgebra by the Weyl group. For a given logarithmic vector field, we can differentiate (Gauss-Manin connection) the primitive form by the vector field, which gives an identification between the module of logarithmic vector fields and the relative de Rham cohomology group. The primitive derivation defines a natural filtration on which the primitive derivation acts by degree shift by one. This structure is very similar to the behavior of Hodge filtrations on the cohomology of the fiber with respect to the Gauss-Manin connection of a proper smooth holomorphic map (the so-called Griffith transversality). This is the reason why the filtration on the module of logarithmic vector fields is called the Hodge filtration.

Key words and phrases. unitary reflection group, logarithmic vector fields, Hodge filtration.
The paper is organized as follows. Section 2 contains preliminaries about complex hyperplane arrangements with $\mathbb{Z}$-valued multiplicities, and recalls the needed background on unitary reflection groups and the necessary properties of flat connections for well-generated unitary reflection groups. In Section 3 we provide an analogue of Saito’s criterion for $\mathbb{Z}$-valued multiplicities, introduce universal vector fields and derive several of their properties. Section 4 contains the main results of this paper as presented above.

For the benefit of the reader, in our proofs we have separated the properties that follow directly from the existence of a universal vector field from those that only hold in the case of well-generated complex reflection groups (where we do have such a universal vector field) see Sections 3.2 and 4.2.

Recall that a complex reflection group $W$ is called well-generated provided it is generated by $\ell$ reflections, where $\ell$ is the dimension of its reflection representation. See Section 2.2 for an equivalent definition used throughout the paper; here the exponents and coexponents of $W$ add up to the Coxeter number of $W$ in a particular fashion, see (2.6).

We finish this introduction with a brief discussion of the crucial differences and similarities of the situations for real and complex reflection arrangements; for definitions we refer to the sections below. Denote by $\nu : \mathcal{A} \to \mathbb{Z}$ a general $\mathbb{Z}$-valued multiplicity function on the reflection arrangement $\mathcal{A}$ of a well-generated irreducible unitary reflection group $W$, and by $\omega : \mathcal{A} \to \mathbb{Z}$ the multiplicity function assigning to a reflecting hyperplane $H$ the order of its pointwise stabilizer, $\omega(H) = e_H = |W_H|$. 

1. If $W$ is real, then $\omega \equiv 2$. In particular, for the module of derivations $\mathcal{D}(\mathcal{A}, \nu - 1)$ of $\mathcal{A}$ with multiplicity $\nu - 1$, we have
   
   $$\mathcal{D}(\mathcal{A}, \nu - 1) = \mathcal{D}(\mathcal{A}, \nu - \omega + 1).$$

   It turns out that the counterpart of the module of derivations $\mathcal{D}(\mathcal{A}, \nu - 1)$ that is used in the literature in the real case is the module $\mathcal{D}(\mathcal{A}, \nu - \omega + 1)$ in the general complex case. One crucial instance, where a $(\nu - 1)$-multiplicity in the real case is replaced by a $(\nu - \omega + 1)$-multiplicity in the complex case, is demonstrated in Theorem 4.19, which generalizes the analogous result from the real case in [Wak11, Thm. 2.7].

2. It is well known that in the real case there is an isomorphism of graded modules
   
   $$\mathcal{D}(\mathcal{A}, -1) = \mathcal{D}(\mathcal{A}, -\omega + 1) \cong \Omega(\mathcal{A}, 1),$$

   where $\Omega(\mathcal{A}, 1)$ is the module of differential 1-forms. As explained in Remark 4.5, by degree comparison, this isomorphism does not extend to complex reflection arrangements that are not the complexification of a real arrangement.

3. The explicit form of the flat connection that was exhibited in [HMRS19], see Proposition 2.17, is the crucial ingredient in the construction of the bases in Theorem 4.2 and of the Hodge filtration in Corollary 4.3. Using this explicit form and a system of flat invariants and of flat derivations has the additional benefit of simplifying the arguments for real reflection arrangements. We remark that, while the existence of flat derivations has been known for some time, see [Bes15], the existence of flat invariants for well-generated complex reflection groups was only discovered quite recently in [KMS20].

4. This paper does not deal with equivariant multiplicities (multiplicities that are constant along hyperplane orbits) as provided in the real case in [ATW12]. That construction is based on a case-by-case analysis of primitive vector fields along reflection subgroups generated by orbits of reflections. We hope for a general conceptual approach to such equivariant multiplicities.
2. Preliminaries

2.1. Multi-arrangements of hyperplanes and their derivations. Let $V$ be a finite-dimensional complex vector space of dimension $\ell$ and fix a Hermitian form $I : V \times V \to \mathbb{C}$ on $V$. Let $S = \text{Sym}(V^*)$ denote the ring of polynomial functions on $V$ and let $F$ denote its quotient field of rational functions. If $x_1, \ldots, x_\ell$ is a basis of $V^*$, we identify $S$ with the polynomial ring $\mathbb{C}[x_1, \ldots, x_\ell]$ and $F$ with the field of rational functions $\mathbb{C}(x_1, \ldots, x_\ell)$.

Letting $S_p$ denote the $\mathbb{C}$-subspace of $S$ consisting of the homogeneous polynomials of degree $p$ (along with $0$), $S$ is naturally $\mathbb{Z}$-graded by $S = \bigoplus_{p \in \mathbb{Z}} S_p$, where we set $S_p = 0$ for $p < 0$. Denote by $\text{Der}_S$ the $S$-module of $\mathbb{C}$-derivations of $S$, and by $\text{Der}_F$ the $F$-module of $\mathbb{C}$-derivations of $F$. Then $\partial_{x_1}, \ldots, \partial_{x_\ell}$ is an $S$-basis of $\text{Der}_S$ and an $F$-basis of $\text{Der}_F$.

We say that $\theta \in \text{Der}_F$ is homogeneous of polynomial degree $p - q$ provided $\theta = \sum g_i \partial_{x_i}$, where $f_i \in S_p$ and $g_i \in S_q \setminus \{0\}$ for each $1 \leq i \leq \ell$. In this case we write $\text{pdeg} \theta = p - q$. Recall that, for $\theta \in \text{Der}_F$, we have $\theta = \theta(x_1)\partial_{x_1} + \cdots + \theta(x_\ell)\partial_{x_\ell}$. The Saito matrix of $\theta_1, \ldots, \theta_\ell \in \text{Der}_F$ is given by

$$M(\theta_1, \ldots, \theta_\ell) := \begin{bmatrix} \theta_1(x_1) & \cdots & \theta_1(x_\ell) \\ \vdots & \ddots & \vdots \\ \theta_\ell(x_1) & \cdots & \theta_\ell(x_\ell) \end{bmatrix},$$

see [OT92, Def. 4.11]. That is, the Saito matrix collects in the $i$-th row the coefficients of $\theta_i$ in the $F$-basis $\{\partial_{x_1}, \ldots, \partial_{x_\ell}\}$ of $\text{Der}_F$.

Extending Ziegler’s concept of an $\mathbb{N}$-valued multiplicity function from [Zie89], a multi-arrangement $(\mathcal{A}, \nu)$ together with a multiplicity function $\nu : \mathcal{A} \to \mathbb{Z}$ assigning to each hyperplane $H \in \mathcal{A}$ a multiplicity $\nu(H) \in \mathbb{Z}$. We use the term multi-arrangement even though we allow hyperplanes to have negative multiplicities, while disregarding hyperplanes of multiplicity zero. We only consider central multi-arrangements $(\mathcal{A}, \nu)$, i.e., $0 \in H$ for every $H \in \mathcal{A}$. In this case, we fix $\alpha_H \in V^*$ with $H = \ker(\alpha_H)$ for $H \in \mathcal{A}$ which we scale so that $I^*(\alpha_H, \alpha_H) = 1$. The defining rational function $Q(\mathcal{A}, \nu)$ is

$$Q(\mathcal{A}, \nu) := \prod_{H \in \mathcal{A}} \alpha_H^{\nu(H)},$$

which we sometimes abbreviate as $Q_\nu := Q(\mathcal{A}, \nu)$. We set $|\nu| := \sum_{H \in \mathcal{A}} \nu(H)$ to be the degree of $Q_\nu$ and separate $Q_\nu$ via $Q_\nu = Q_+ / Q_-$ with

$$Q_+ := \prod_{H \in \mathcal{A}, \nu(H) > 0} \alpha_H^{\nu(H)}, \quad Q_- := \prod_{H \in \mathcal{A}, \nu(H) < 0} \alpha_H^{-\nu(H)}.$$

To deal with general multiplicity functions on the arrangement $\mathcal{A}$, we also set

$$Q_{\mathcal{A}} := Q(\mathcal{A}, 1) = \prod_{H \in \mathcal{A}} \alpha_H$$

to be the defining polynomial of the simple arrangement $\mathcal{A}$ which we later abbreviate as $Q = Q_{\mathcal{A}}$ when $\mathcal{A}$ is clear from the context.

**Definition 2.2.** Let $S_{(\alpha_H)}$ be the localization of the ring $S$ at the prime ideal $(\alpha_H)$. Setting $S' := S[S_{(\mathcal{A})}^{-1}]$, the $S$-module of logarithmic vector fields on $\mathcal{A}$ is defined by

$$\mathcal{D}(\mathcal{A}, -\infty) := \{ \theta \in \text{Der}_{S'} \mid \theta(\beta) \in S_{(\alpha_H)} \text{ for } H \in \mathcal{A} \text{ and } \beta \in V^* \text{ with } I^*(\alpha_H, \beta) = 0 \}.$$

Given a multiplicity function $\nu : \mathcal{A} \to \mathbb{Z}$, define the $S$-module of $(\mathcal{A}, \nu)$-derivations by

$$\mathcal{D}(\mathcal{A}, \nu) := \{ \theta \in \mathcal{D}(\mathcal{A}, -\infty) \mid \theta(\alpha_H) \in \alpha_H^{\nu(H)} S_{(\alpha_H)} \text{ for } H \in \mathcal{A} \}.$$
Observe that in general this definition depends on the chosen Hermitian form, while \( D(\mathcal{A},0) = \text{Der}_S \). We remark also that the given definition is an equivalent reformulation of the definitions given in [AT10, Wak11].

We record the following basic containment property for multiplicities \( \mu \geq \nu \), i.e., \( \mu(H) \geq \nu(H) \) for all \( H \in \mathcal{A} \).

**Lemma 2.3.** We have \( \mu > \nu \) if and only if \( D(\mathcal{A},\mu) \subsetneq D(\mathcal{A},\nu) \). In particular, we have \( D(\mathcal{A},\mu) \subseteq \text{Der}_S \) if and only if \( \mu \geq 0 \).

**Proof.** The reverse implication of the asserted equivalence, as well as the fact that \( \mu \geq \nu \) implies \( D(\mathcal{A},\mu) \subseteq D(\mathcal{A},\nu) \) are immediate from the definition. For \( \mu > \nu \), let \( H \in \mathcal{A} \) with \( \mu(H) > \nu(H) \). If \( \nu(H) \geq 0 \), then \( \mathcal{Q}_+ \partial_\alpha_H \in D(\mathcal{A},\nu) \setminus D(\mathcal{A},\mu) \), and if \( \nu(H) < 0 \), then \( \alpha_H^\nu Q_+ \partial_\alpha_H \in D(\mathcal{A},\nu) \setminus D(\mathcal{A},\mu) \), where \( Q_+ \) is as in (2.1). \( \square \)

The multi-arrangement \( (\mathcal{A},\nu) \) is free if \( D(\mathcal{A},\nu) \) is a free \( S \)-module. In this case, \( D(\mathcal{A},\nu) \) admits a basis \( \{ \theta_1, \ldots, \theta_\ell \} \) of homogeneous derivations, see [OT92, Thm A.20]. While the \( \theta_i \)'s are not unique, their polynomial degrees \( \text{pdeg} \theta_i \) are, see [OT92, Prop. A.24]. The multiset of these polynomial degrees is the multiset of \textit{exponents} of the free multi-arrangement \( (\mathcal{A},\nu) \). It is denoted by

\[
\exp(\mathcal{A},\nu) := \{ \text{pdeg}(\theta_1), \ldots, \text{pdeg}(\theta_\ell) \}.
\]

### 2.2. Unitary reflection groups and their reflection arrangements

Let \( W \) be an irreducible unitary reflection group with reflection representation \( V \cong \mathbb{C}^\ell \), and let \( I \) be the associated \( W \)-invariant Hermitian inner form. We refer to [HMRS19] and the references therein for all necessary background material on reflection groups. Denote the set of reflections of \( W \) by \( \mathcal{R} = \mathcal{R}(W) \), and the associated reflection arrangement in \( V \) by \( \mathcal{A} = \mathcal{A}(W) \). For \( H \in \mathcal{A} \), let \( e_H \) denote the order of the pointwise stabilizer of \( H \) in \( W \). The \textbf{Coxeter number} of \( W \) is given by

\[
h = h_W := \frac{1}{\ell} \sum_{H \in \mathcal{A}} e_H = \frac{1}{\ell} \left( |\mathcal{R}| + |\mathcal{A}| \right),
\]

generalizing the usual Coxeter number of a real reflection group to irreducible unitary reflection groups.

Before proceeding, we record, without proof, the following well-known property of the \( W \)-action on polynomial functions.

**Lemma 2.5.** Let \( g \in S \) and let \( H \in \mathcal{A} \) with corresponding reflection \( s \in \mathcal{R} \) with \( \text{Fix}(s) = H \) of order \( e_H \). Let \( \epsilon \) be a primitive \( e_H \)-th root of unity such that \( s(\alpha_H) = \epsilon \alpha_H \). For \( 1 \leq k < e_H \), we have

\[
s(g) = \epsilon^kg \quad \implies \quad g \in \alpha_H^k \cdot S.
\]

Results of Shephard and Todd [ST54] and of Chevalley [Che55] distinguish unitary reflection groups as those finite subgroups of \( \text{GL}(V) \) for which the invariant subalgebra of the action on the symmetric algebra \( S = \text{Sym}(V^*) \cong \mathbb{C}[x_1,\ldots,x_\ell] \) yields again a polynomial algebra,

\[
S^W \cong \mathbb{C}[f_1,\ldots,f_\ell]
\]

for homogeneous polynomials \( f_1,\ldots,f_\ell \) of degrees \( d_i = \deg f_i \) with \( d_1 \leq \cdots \leq d_\ell \). Let \( \text{exp}(W) = \{ e_1 \leq \cdots \leq e_\ell \} \) be the \textit{exponents} of \( W \), where \( e_i = d_i - 1 \) and let \( \text{coexp}(W) = \{ e_1^* \leq \cdots \leq e_\ell^* \} \) be the \textit{coexponents} of \( W \), cf. [OT92, Def. 6.50]. The group \( W \) is called \textit{well-generated} if it is generated by \( \ell \) reflections, or, equivalently, if

\[
e_i + e_{\ell+1-i}^* = h \quad \text{for } 1 \leq i \leq \ell,
\]
see [OS80]. Terao showed in [Ter80] that the reflection arrangement \( \mathcal{A} = \mathcal{A}(W) \) of \( W \) is free, and that the exponents coincide with the coexponents of \( W \), cf. [OT92, Thm. 6.60],

\[
\exp \mathcal{A} = \coexp(W).
\]

This shows that \( e_1^* = 1 \) (coming from the Euler derivation, see below), implying that \( e_\ell = h - 1 \) in the case of well-generated groups.

For later usage, we recall from [HMRS19, Sec. 3] the diagonal matrix

\[
B_{\infty} := \frac{1}{h} \text{diag}(e_i) - \mathbb{1}_\ell.
\]

Next we recall from [HMRS19] the order multiplicity \( \omega \) of the reflection arrangement \( \mathcal{A} = \mathcal{A}(W) \) defined by \( \omega(H) = e_H \) for \( H \in \mathcal{A} \). In other words, the multiplicities are chosen so that the defining polynomial \( Q(\mathcal{A}, \omega) \) of the multi-arrangement \( (\mathcal{A}, \omega) \) is the discriminant of \( W \), cf. [OT92, Def. 6.44],

\[
Q(\mathcal{A}, \omega) = \prod_{H \in \mathcal{A}(W)} \alpha_H^{e_H} = QJ,
\]

where \( Q = Q_\mathcal{A} = \prod_{H \in \mathcal{A}} \alpha_H \) as before, and \( J = J_\mathcal{A} := \prod_{H \in \mathcal{A}} \alpha_H^{-1}. \)

2.3. Flat connections for well-generated unitary reflection groups. Throughout this subsection let \( W \) be a well-generated unitary reflection group. Let \( \nabla : \text{Der}_F \times \text{Der}_F \to \text{Der}_F \) be the connection defined by

\[
\nabla_\theta(\phi) = \sum_i \theta(p_i) \partial_{x_i}
\]

for \( \theta, \phi \in \text{Der}_F \) with \( \phi = \sum p_i \partial_{x_i} \), or equivalently, an affine connection which has \( \partial_{x_i} \) as a flat section, i.e., \( \nabla_\theta(\partial_{x_i}) = 0 \). Recall that \( \nabla \) is \( F \)-linear in the first parameter and \( \mathbb{C} \)-linear in the second, satisfying the Leibniz rule

\[
\nabla_\theta(p\phi) = \theta(p)\phi + p\nabla_\theta(\phi)
\]

for \( \theta, \phi \in \text{Der}_F \) and \( p \in F \). Alternatively, this can be characterized by

\[
\nabla_\theta(\phi)(\alpha) = \theta(\phi(\alpha))
\]

for all \( \alpha \in V^* \). Observe that for \( \theta, \phi \) homogeneous, (2.9) implies that the derivation \( \nabla_\theta(\phi) \) is again homogeneous with polynomial degree

\[
p\text{deg} \left( \nabla_\theta(\phi) \right) = p\text{deg}(\theta) + p\text{deg}(\phi) - 1.
\]

Let \( F_{1,\ldots,\ell}^{\text{fl}} \) be the special homogeneous fundamental invariants in \( \mathbb{C}[x] \) with \( x = (x_1, \ldots, x_\ell) \), as given in [KMS20, Thm. 5.5]. Recall that \( \deg(F_i^{\text{fl}}) = d_i \) and

\[
\mathbb{C}[F_{1,\ldots,\ell}^{\text{fl}}] \cong S^{\mathbb{C}}.
\]

Consider indeterminates \( t = (t_1, \ldots, t_\ell) \) together with the map \( t_i \mapsto F_i^{\text{fl}} \) giving an isomorphism

\[
R := \mathbb{C}[t] \cong \mathbb{C}[F_{1,\ldots,\ell}^{\text{fl}}].
\]

By slight abuse of notation, here and in the rest of the paper, the variable \( t_i \) and its image \( F_i^{\text{fl}} \) under this isomorphism are identified. Set moreover \( T := \mathbb{C}[t'] = \mathbb{C}[t_1, \ldots, t_{\ell-1}] \), the subring of \( \mathbb{C}[t] \) generated by \( t' = (t_1, \ldots, t_{\ell-1}) \).
As usual, set
\[ J_{\partial/\partial x} := \left( \frac{\partial}{\partial x_1}, \ldots, \frac{\partial}{\partial x_\ell} \right) (t_1, \ldots, t_\ell) = \left[ \frac{\partial t_1}{\partial x_1} \cdots \frac{\partial t_\ell}{\partial x_1} \vphantom{\frac{\partial t_1}{\partial x_1}} \right] \in \mathbb{C}[x]^\ell \times \ell \]
with inverse matrix \[ J_{\partial/\partial x}^{-1} = (\partial_1, \ldots, \partial_\ell)^{tr}(x_1, \ldots, x_\ell). \] It is well-known that \[ \det J_{\partial/\partial x} = J = \prod_{H \in \mathfrak{I}} c_H^{e_H - 1}, \]
see [OT92, Thm. 6.42]. Here and elsewhere the symbol \( \equiv \) denotes, as usual, equality up to a non-zero complex constant factor.

The \textit{primitive vector field} \( D := \partial_\ell \in \text{Der}_R \) is given by
\begin{equation}
(2.12) \quad D = \det J_{\partial/\partial x} \left[ \begin{array}{c c c c}
\frac{\partial t_1}{\partial x_1} & \cdots & \frac{\partial t_\ell}{\partial x_1} \\
\vphantom{\frac{\partial t_1}{\partial x_1}} & \ddots & \vdots \\
\vdots & \ddots & \vdots \\
\frac{\partial t_1}{\partial x_\ell} & \cdots & \frac{\partial t_\ell}{\partial x_\ell}
\end{array} \right] \in \text{Der}_F.
\end{equation}

In particular, \( D \) is homogeneous of degree \( pdeg(D) = -e_\ell = -(h-1) \), where we observe that \( h = d_0 > d_{\ell-1} \). The primitive vector field \( D \) is thus, up to a non-zero complex constant, independent of the given choice of fundamental invariants.

Consider \( X := V/W = \text{Spec}(\mathbb{C}[t]) \) and let \( \Delta(t) \in R \) be the discriminant of \( W \) given by
\[ \Delta(F^0_1(x), \ldots, F^0_\ell(x)) = \prod_{H \in \mathfrak{I}} c_H^{e_H} \]
with vanishing locus \( \mathcal{H} := \{ \overline{p} \in X \mid \Delta(\overline{p}) = 0 \} \), cf. [OT92, Def. 6.44]. Let \( \text{Der}_R \) be the \( R \)-module of logarithmic vector fields, and let
\[ \text{Der}_R\!(-\log \Delta) := \{ \theta \in \text{Der}_R \mid \theta \Delta \in R\Delta \} \]
be the module of logarithmic vector fields along \( \mathcal{H} \). We have an \( R \)-isomorphism between such logarithmic vector fields and \( W \)-invariant \( S \)-derivations,
\begin{equation}
(2.13) \quad \text{Der}_R\!(\!-\log \Delta) \cong \text{Der}_S^W, \quad \text{and \ Der}_R\!(\!-\log \Delta) \text{ is a free } R \text{-module, cf. [OT92, Cor. 6.58].}
\end{equation}

Bessis showed in [Bes15, Thm. 2.4] that there exists a \textit{system of flat homogeneous derivations} \( \{\eta_1, \ldots, \eta_\ell\} \) of \( \text{Der}_R\!(\!-\log \Delta) \) with \( pdeg \eta_i = e_i^+ \) being the \( i \)-th coexponent of \( W \). This means, its Saito matrix
\begin{equation}
(2.14) \quad M_\eta := M(\eta_1, \ldots, \eta_\ell) = \left[ \begin{array}{c c}
\eta_1(t_1) & \cdots & \eta_\ell(t_\ell) \\
\vdots & \ddots & \vdots \\
\eta_1(t_1) & \cdots & \eta_\ell(t_\ell)
\end{array} \right]
\end{equation}
decomposes as
\begin{equation}
(2.15) \quad M_\eta = t_\ell \, \mathbb{1} + M^{(0)}(t')
\end{equation}
with \( M^{(0)}(t') \in \mathbb{C}[t']^\ell \times \ell. \) As before, we have \( (\eta_1, \ldots, \eta_\ell)^{tr} = M_\eta(\partial_1, \ldots, \partial_\ell)^{tr} \). Moreover, we obtain that \( \Delta(t) \) is a monic polynomial in \( t_\ell \) with coefficients in \( T \), i.e.,
\[ \Delta(t) = t_\ell^{e_\ell} + a_{\ell-1}(t') t_\ell^{e_{\ell-1}} + \ldots + a_1(t') t_\ell + a_0(t'), \]
where \( a_i(t') \in T \) for \( 1 \leq i \leq \ell \). As observed in [KMS20, Lem. 3.8], such a system of flat homogeneous derivations is unique, and we have that \( \eta_1 = \frac{1}{\ell} \sum d_i t_i \partial_\ell \in \text{Der}_R \) is the \textit{Euler vector field} mapped to the (scaled) \textit{Euler derivation}
\begin{equation}
(2.16) \quad E := \frac{1}{\ell} \sum x_i \partial_\ell \in \text{Der}_S^W.
\end{equation}
under the isomorphism in (2.13), see [KMS20, Lem. 3.5].

We recall from [HMRS19, Prop. 3.15] the following proposition which is the key ingredient in the present considerations. It involves the diagonal matrix $B_\infty$ given in (2.8).

**Proposition 2.17.** We have $T$-isomorphisms
\[
\nabla_D : \text{Der}_R(-\log \Delta) \rightarrow \text{Der}_R \\
\nabla_D^{-1} : \text{Der}_R \rightarrow \text{Der}_R(-\log \Delta)
\]
given by
\[
\nabla_D \begin{pmatrix} \partial_{t_1} \\ \vdots \\ \partial_{t_\ell} \end{pmatrix} = -M^{-1}_\eta(B_\infty + \mathbb{I}_\ell) \begin{pmatrix} \partial_{t_1} \\ \vdots \\ \partial_{t_\ell} \end{pmatrix} \\
\nabla_D^{-1} \begin{pmatrix} \partial_{t_1} \\ \vdots \\ \partial_{t_\ell} \end{pmatrix} = -B^{-1}_\infty \begin{pmatrix} \eta_\ell \\ \vdots \\ \eta_1 \end{pmatrix} = -B^{-1}_\infty M^{-1}_\eta \begin{pmatrix} \partial_{t_1} \\ \vdots \\ \partial_{t_\ell} \end{pmatrix}.
\]

From this explicit description of $\nabla_D$, the following Hodge filtration of $\text{Der}_R$ was deduced in [HMRS19, Prop. 3.15], generalizing Saito’s construction for Coxeter arrangements in [Sai93] to the situation for well-generated unitary reflection groups. Let $G_0$ be the $T$-submodule of $\text{Der}_R$ generated by $\partial_{t_1}, \ldots, \partial_{t_\ell}$ and let
\[
G_k := \nabla_D^{-k}(G_0) \text{ for } k \in \mathbb{Z}.
\]

Then the Hodge filtration of $\text{Der}_R$ is given by
\[
H^{(k)}_0 := \bigoplus_{i \geq k} G_i.
\]

3. A general version of Saito’s criterion and universal vector fields

Throughout this section, we consider a general multi-arrangement $(\mathcal{A}, \nu)$ in $V \cong \mathbb{C}_H$ with multiplicity function $\nu : \mathcal{A} \rightarrow \mathbb{Z}$.

3.1. A general version of Saito’s criterion. For later usage we generalize Ziegler’s version of Saito’s criterion [Zie89, Thm. 8] for multi-arrangements from $\mathbb{N}$- to $\mathbb{Z}$-valued multiplicities.

**Theorem 3.1.** For a multiplicity function $\nu : \mathcal{A} \rightarrow \mathbb{Z}$, let $\theta_1, \ldots, \theta_\ell \in \mathcal{D}(\mathcal{A}, \nu)$. Then the following are equivalent:

(i) $\{\theta_1, \ldots, \theta_\ell\}$ is an $S$-basis of $\mathcal{D}(\mathcal{A}, \nu)$.

(ii) $\det(M(\theta_1, \ldots, \theta_\ell)) = Q(\mathcal{A}, \nu)$.

Moreover, if each $\theta_i$ is homogeneous, then (i) and (ii) are equivalent to

(iii) $\theta_1, \ldots, \theta_\ell$ are linearly independent over $S$ and $\sum \text{pdeg} \theta_i = |\nu|$.

We require two lemmas for the proof of Theorem 3.1. Recall from (2.1) that we write $Q_\nu = Q_+ / Q_- \in S$ for the defining rational function $Q_\nu = Q(\mathcal{A}, \nu)$.

**Lemma 3.2.** Let $\theta \in \mathcal{D}(\mathcal{A}, \nu)$. Then $Q_- \theta \in \text{Der}_S$.

**Proof.** Fix $H \in \mathcal{A}$ and let $\alpha_H = x_1, x_2, \ldots, x_\ell$ be an orthonormal basis of $V^\ast$. Set $Q := Q_\mathcal{A}$ and $Q_H := Q / \alpha_H$. Write $\theta = \sum_i (f_i/Q^\nu)\partial_{x_i}$ with $f_i \in S$ and $n \geq 0$. Then $\theta \in \mathcal{D}(\mathcal{A}, \nu)$ means that
\[
f_1 \in \alpha_H^{n+\nu(H)} \cdot S \\
f_i \in \alpha_H^n \cdot S \text{ for } 2 \leq i \leq \ell.
\]
or, equivalently, that \( \theta = \sum_i (f_i' / Q_H^i) \partial_{x_i} \) with

\[
(3.3) \quad f_i' \in \alpha_H^{\nu(H)} \cdot S \quad f_i' \in S \text{ for } 2 \leq i \leq \ell.
\]

With \( Q_H^i \in S_{(\alpha_H)} \), we obtain that \( Q_\ell f_i \in S_{(\alpha_H)} \) for all \( 1 \leq i \leq \ell \) and thus \( \theta \in \text{Der}_{S_{(\alpha_H)}} \).

Since this holds for any \( H \in \mathcal{A} \), we conclude that \( Q_\ell \theta \in \text{Der}_S \).

In the subsequent arguments, we use the following abbreviation. Given \( \theta_1, \ldots, \theta_\ell \in \text{Der}_F \), we set

\[
\theta_1 \wedge \cdots \wedge \theta_\ell := \det(M(\theta_1, \ldots, \theta_\ell)) = \det(\theta_i(x_j))_{1 \leq i, j \leq \ell} \in F.
\]

**Lemma 3.4.** Let \( \nu : \mathcal{A} \to \mathbb{Z} \) and let \( \theta_1, \ldots, \theta_\ell \in \mathcal{D}(\mathcal{A}, \nu) \). Then

\[
\theta_1 \wedge \cdots \wedge \theta_\ell \in Q_\nu \cdot S.
\]

**Proof.** Let \( H \in \mathcal{A} \) and consider the orthonormal basis \( \alpha_H = x_1, x_2, \ldots, x_\ell \) of \( V^* \). Since \( \theta_i \in \mathcal{D}(\mathcal{A}, \nu) \), we have

\[
\theta_i(\alpha_H) \in \alpha_H^{\nu(H)} \cdot S_{(\alpha_H)} \quad \text{and} \quad \theta_i(x_j) \in S_{(\alpha_H)} \text{ for } 2 \leq j \leq \ell.
\]

This implies that \( \theta_1 \wedge \cdots \wedge \theta_\ell \in \alpha_H^{\nu(H)} \cdot S_{(\alpha_H)} \). As this holds for any \( H \in \mathcal{A} \), the lemma follows.

**Proof of Theorem 3.1.** First we show that (ii) implies (i). As \( \theta_1 \wedge \cdots \wedge \theta_\ell \neq 0 \), we readily see that \( \theta_1, \ldots, \theta_\ell \) are \( S \)-independent. So we aim to show that they span \( \mathcal{D}(\mathcal{A}, \nu) \). To this end, let \( \theta \in \mathcal{D}(\mathcal{A}, \nu) \). Since \( \theta_i \in \mathcal{D}(\mathcal{A}, \nu) \) for \( 1 \leq i \leq \ell \), we have \( Q_\ell \theta_i \in \text{Der}_S \) by Lemma 3.2. Let \( M := M(Q_\ell \theta_1, \ldots, Q_\ell \theta_\ell) \) and observe that

\[
\det(M) = Q_\ell \theta_1 \wedge \cdots \wedge Q_\ell \theta_\ell = Q_\ell^T Q_\nu.
\]

Set \( N = M^{-1} \) and \( \tilde{N} = \det(M)^{-1} N \in S^{\ell \times \ell} \). Since

\[
\det(M) \partial_{x_i} = \sum_j \tilde{N}_{ij} Q_\ell \theta_j,
\]

we see that \( Q_\ell \theta_1, \ldots, Q_\ell \theta_\ell \) generate \( Q_\ell^T Q_\nu \cdot \text{Der}_S \) over \( S \). With \( Q_\ell \theta \in \text{Der}_S \), we obtain

\[
\det(M)Q_\ell \theta = Q_\ell^T Q_\ell \theta = \sum_{i=1}^\ell f_i Q_\ell \theta_i
\]

for \( f_1, \ldots, f_\ell \in S \), or, equivalently, \( Q_\ell^T Q_\ell^{-1} \theta = \sum f_i \theta_i \). It thus remains to show that each \( f_i \) is divisible by \( Q_\ell^T Q_\ell^{-1} = Q_\nu Q_\nu^T \). We have

\[
f_i Q_\nu = f_i Q_\ell (\theta_1 \wedge \cdots \wedge \theta_\ell)
\]

\[
= \theta_1 \wedge \cdots \wedge \theta_i-1 \wedge f_i Q_\ell \theta_i \wedge \theta_{i+1} \wedge \cdots \wedge \theta_\ell
\]

\[
= Q_\ell^T (\theta_1 \wedge \cdots \wedge \theta_i-1 \wedge \theta \wedge \theta_{i+1} \wedge \cdots \wedge \theta_\ell)
\]

\[
= Q_\ell^T g_i Q_\nu,
\]

for some \( g_i \in S \) given by Lemma 3.4. This implies \( f_i = Q_\nu Q_\ell^T g_i \), as desired.

We next show (i) implies (ii). By Lemma 3.4, we may write \( \theta_1 \wedge \cdots \wedge \theta_\ell = f Q_\nu = f Q_+ / Q_- \) for some \( f \in S \). Since \( \theta_1, \ldots, \theta_\ell \) are \( S \)-independent, we have \( f \neq 0 \). We thus need to show that \( f \) is constant. Now, let \( H \in \mathcal{A} \) and again assume that \( \alpha_H = x_1, \ldots, x_\ell \) are orthonormal coordinates. Set

\[
Q_+ = \alpha_H^{m_+} Q_+ \quad \text{and} \quad Q_- = \alpha_H^{m_-} Q_-
\]

such that \( Q_+^T \) and \( Q_-^T \) are both not divisible by \( \alpha_H \).
First, observe that
\[ Q_+ \partial_{\alpha_H}, Q'_+ \partial_{x_2}, \ldots, Q'_+ \partial_{x_\ell} \in \mathcal{D}(\mathcal{A}, \nu), \]
by definition. This implies
\[ Q_+(Q'_+)^{\ell-1} = Q_+ \partial_{\alpha_H} \wedge Q'_+ \partial_{x_2} \wedge \ldots \wedge Q'_+ \partial_{x_\ell} \]
\[ = \det(g_{ij}) (\theta_1 \wedge \ldots \wedge \theta_\ell) \]
\[ = g f Q_+/Q_- \]
where \((g_{ij})\) is the matrix with entries in \(S\) expressing \(Q_+ \partial_{\alpha_H}, Q'_+ \partial_{x_2}, \ldots, Q'_+ \partial_{x_\ell}\) in terms of the basis \(\theta_1, \ldots, \theta_\ell\), and where we wrote \(g = \det(g_{ij}) \in S\). This means that \(f\) is a factor of \(Q_- (Q'_+)^{\ell-1}\) for the given \(H \in \mathcal{A}\). Repeating this argument for every hyperplane in \(\mathcal{A}\), we obtain that \(f\) is a factor of \(Q_-\).

Second, we also observe that
\[ \frac{Q_+}{\alpha_{\mathcal{A}}} \partial_{\alpha_H}, Q_+ \partial_{x_2}, \ldots, Q_+ \partial_{x_\ell} \in \mathcal{D}(\mathcal{A}, \nu) \]
and analogously deduce that
\[ \frac{Q_+}{\alpha_{\mathcal{A}}} = g' f Q_+/Q_- \]
for some \(g' \in S\). This now means that \(f\) is a factor of \(Q_- (Q'_+)^{\ell-1}\) for the given \(H \in \mathcal{A}\). Once again repeating this for every hyperplane in \(\mathcal{A}\), we obtain that \(f\) is a factor of \((Q'_+)^{\ell-1}\). As \(Q_-\) and \(Q_+\) do not have any common non-scalar factors, we thus deduce that \(f\) is constant.

The argument for (iii) is standard. If \(\{\theta_1, \ldots, \theta_\ell\}\) forms a homogeneous \(S\)-basis of \(\mathcal{D}(\mathcal{A}, \nu)\), then (iii) is obviously satisfied. Vice versa, (iii) implies that the determinant of \(M(\theta_1, \ldots, \theta_\ell)\) equals \(f Q_\nu\) for some \(f \in S \setminus \{0\}\) by independence, and that \(\deg(f) = 0\), because the degrees of \(\det(M(\theta_1, \ldots, \theta_\ell))\) and of \(Q_\nu\) coincide.

3.2. Properties of universal vector fields on multi-arrangements. In this section, we define universal vector fields for general arrangements and arbitrary multiplicity functions and explore properties of logarithmic vector fields that follow from the existence of universal vector fields. Throughout, we have separated the arguments as detailed as possible to clarify their exact interplay. In Section 4.2, we exhibit natural occurrences and properties of universal vector fields in the case of reflection arrangements. We start with the definition of universality depending on a multiplicity \(\nu : \mathcal{A} \to \mathbb{Z}\) which is a slight generalization of the \(\mathbf{k}\)-universality in the real case in [Wak11, Def. 2.2].

Recall the definition of the affine connection \(\nabla\) in (2.9) having \(\partial_{x_i}\) as a flat section.

**Definition 3.5.** Let \((\mathcal{A}, \nu)\) be a multi-arrangement for a multiplicity function \(\nu : \mathcal{A} \to \mathbb{Z}\) and let \(\zeta \in \mathcal{D}(\mathcal{A}, -\infty)\) be homogeneous. Then \(\zeta\) is called \(\nu\)-universal provided the map
\[ \Phi_\zeta : \text{Der}_F \longrightarrow \mathcal{D}(\mathcal{A}, \nu); \quad \theta \longmapsto \nabla_\theta(\zeta) \]
is an isomorphism of \(S\)-modules.

Observe that \(\Phi_\zeta\) is \(S\)-linear by definition. The \(\nu\)-universality of \(\zeta\) thus means that \(\Phi_\zeta : \text{Der}_S \longrightarrow \mathcal{D}(\mathcal{A}, \nu)\) is well-defined and bijective. In particular, this implies for an \(\nu\)-universal \(\zeta\) that \((\mathcal{A}, \nu)\) is free and
\[ \{\nabla_{\partial_{x_i}}(\zeta) \mid 1 \leq i \leq \ell\} \]
is an \(S\)-module basis of \(\mathcal{D}(\mathcal{A}, \nu)\).

We begin with the following observation from [Wak11, Ex. 2.3].
Lemma 3.6. The Euler derivation $E$ defined in (2.16) is $0$-universal.

Proof. Since $\Phi_E(\delta) = \nabla_\delta(E) = \delta$ for any $\delta \in \text{Der}_S$, the statement follows. \hfill \Box

Lemma 3.7. Let $\theta \in \text{Der}_S$ and $\zeta \in \mathcal{D}(\mathcal{A}, -\infty)$. Then $\nabla_\theta(\zeta) \in \mathcal{D}(\mathcal{A}, -\infty)$.

Proof. Let $H \in \mathcal{A}$ and let $\beta \in V^*$ such that $I^*(\alpha_H, \beta) = 0$. Since $\zeta \in \mathcal{D}(\mathcal{A}, -\infty)$, we have $\zeta(\beta) = f/Q_H$ for $f \in S$ and $Q_H = (\frac{Q}{\alpha_H})^n$ for some $n \geq 0$. Using (2.10), we obtain

$$\nabla_\theta(\zeta)(\beta) = \theta(f/Q_H) = \frac{1}{Q_H^2} (\theta(f)\tilde{Q}_H - f\theta(\tilde{Q}_H)).$$

Since $\theta \in \text{Der}_S$ by assumption, we obtain $\nabla_\theta(\zeta)(\beta) \in S_{(\alpha_H)}$. This holds for any $H \in \mathcal{A}$ and we deduce the statement. \hfill \Box

Lemma 3.8. Let $\mu : \mathcal{A} \to \{0, 1\}$ and let $\zeta \in \mathcal{D}(\mathcal{A}, -\infty)$. Then $\zeta \in \mathcal{D}(\mathcal{A}, \nu + 1)$ if and only if $\Phi_{\zeta} : \mathcal{D}(\mathcal{A}, \mu) \to \mathcal{D}(\mathcal{A}, \nu + \mu)$ is well-defined.

Proof. Let $\zeta \in \mathcal{D}(\mathcal{A}, \nu + 1)$. We aim to show that $\nabla_\theta(\zeta) \in \mathcal{D}(\mathcal{A}, \nu + \mu)$ for all $\theta \in \mathcal{D}(\mathcal{A}, \mu)$. By Lemma 3.7 we have that $\nabla_\theta(\zeta) \in \mathcal{D}(\mathcal{A}, -\infty)$ in this case. The following argument is analogous to the proof of the previous lemma. Let $H \in \mathcal{A}$. Since $\zeta \in \mathcal{D}(\mathcal{A}, \nu + 1)$, we have that

$$\zeta(\alpha_H) = \alpha_H^{\nu(H)+1} f/Q_H$$

for $f \in S$ and $Q_H = (\frac{Q}{\alpha_H})^n$ for some $n \geq 0$. Using (2.10), for $\theta \in \mathcal{D}(\mathcal{A}, \mu)$ we have

$$\nabla_\theta(\zeta)(\alpha_H) = \theta(\alpha_H^{\nu(H)+1} f/Q_H)$$

$$= \frac{1}{Q_H^2} (\theta(\alpha_H^{\nu(H)+1}) fQ_H + \alpha_H^{\nu(H)+1} \theta(f)Q_H - \alpha_H^{\nu(H)+1} f\theta(Q_H))$$

$$= \alpha_H^{\nu(H)} (\nu(H) + 1)\theta(\alpha_H)fQ_H + \alpha_H\theta(f)Q_H - \alpha_Hf\theta(Q_H)).$$

This yields $\nabla_\theta(\zeta)(\alpha_H) \in \alpha_H^{\nu(H)} S_{(\alpha_H)}$. If $\mu(H) = 1$, we moreover get $\theta(\alpha_H) \in \alpha_H \cdot S$ by the defining property of $\theta \in \mathcal{D}(\mathcal{A}, \mu)$. In this case, we thus get an additional factor $\alpha_H$ in (3.9) and obtain $\nabla_\theta(\zeta)(\alpha_H) \in \alpha_H^{\nu(H)+1} S_{(\alpha_H)}$. In any event $\Phi_{\zeta}(\theta)$ belongs to $\mathcal{D}(\mathcal{A}, \nu + \mu)$.

Assume now that $\Phi_{\zeta} : \mathcal{D}(\mathcal{A}, \mu) \to \mathcal{D}(\mathcal{A}, \nu + \mu)$ is well-defined. Let $\tau$ be the maximal multiplicity function such that $\zeta \in \mathcal{D}(\mathcal{A}, \tau + 1)$. This is,

$$\zeta(\alpha_H) = \alpha_H^{\tau(H)+1} f/Q_H$$

for $f \in S$ and $Q_H = (\frac{Q}{\alpha_H})^n$ for some $n \geq 0$, such that $f \notin \alpha_H \cdot S$. As in (3.9), for $\theta \in \mathcal{D}(\mathcal{A}, \mu)$ we obtain

$$\nabla_\theta(\zeta)(\alpha_H) = \frac{\alpha_H^{\tau(H)}}{Q_H^2} ((\tau(H) + 1)\theta(\alpha_H)fQ_H + \alpha_H\theta(f)Q_H - \alpha_Hf\theta(Q_H)).$$

Observe that $\theta = Q_{\mu} \partial_{\alpha_H} \in \mathcal{D}(\mathcal{A}, \mu)$. If $\mu(H) = 0$, then for $\theta = Q_{\mu} \partial_{\alpha_H}$, we have $\nabla_\theta(\zeta)(\alpha_H) \in \alpha_H^{\tau(H)} S_{(\alpha_H)}$ but $\nabla_\theta(\zeta)(\alpha_H) \notin \alpha_H^{\tau(H)+1} S_{(\alpha_H)}$, since the first summand in (3.10) is not divisible by $\alpha_H$ while the other two are. By the well-definedness of $\Phi_{\zeta}$, we thus have $\tau(H) \geq \nu(H)$.

Similarly, if $\mu(H) = 1$, then the first summand (3.10) is divisible by $\alpha_H$ but not by $\alpha_H^2$, while the other two are divisible by $\alpha_H^2$. Again by the well-definedness of $\Phi_{\zeta}$, we have that $\tau(H) \geq \nu(H)$. We conclude that $\tau \geq \nu$ and so by definition, we get

$$\zeta \in \mathcal{D}(\mathcal{A}, \tau + 1) \subseteq \mathcal{D}(\mathcal{A}, \nu + 1).$$
The following lemma is the analogue of [Wak11, Prop. 2.6(3)] in our setting.

**Lemma 3.11.** Let \( \zeta \) be \( \nu \)-universal. Then \( \zeta \notin \mathcal{D}(\mathcal{A}, \mu + 1) \) for any \( \mu > \nu \).

**Proof.** Let \( \mu > \nu \) and suppose that \( \zeta \in \mathcal{D}(\mathcal{A}, \mu + 1) \). Lemmas 2.3 and 3.8 then imply that \( \Phi_\zeta(\text{Der}_S) \subseteq \mathcal{D}(\mathcal{A}, \mu) \subseteq \mathcal{D}(\mathcal{A}, \nu) \). This contradicts the fact that \( \Phi_\zeta(\text{Der}_S) = \mathcal{D}(\mathcal{A}, \nu) \) owed to the \( \nu \)-universality of \( \zeta \). \( \square \)

Lemmas 3.8 and 3.11 give the following theorem, generalizing [AY09, Thm. 2] to the complex case and to the more general notion of universality above, see also [Wak11, Prop. 2.7].

**Theorem 3.12.** Let \( \mu : \mathcal{A} \to \{0, 1\} \) and let \( \zeta \) be \( \nu \)-universal. Then
\[
\Phi_\zeta : \mathcal{D}(\mathcal{A}, \mu) \longrightarrow \mathcal{D}(\mathcal{A}, \nu + \mu)
\]
is an isomorphism of \( S \)-modules.

Observe that in the theorem we do not require any freeness assumption on \( (\mathcal{A}, \mu) \). Together with Theorem 4.17 below, it thus generalizes [HMRS19, Thm. 3.22].

**Proof.** We already know that \( \Phi_\zeta \) is \( S \)-linear and well-defined by Lemma 3.8. Moreover, the universality of \( \zeta \) implies that \( \Phi_\zeta \) is injective on \( \text{Der}_S \) and thus on \( \mathcal{D}(\mathcal{A}, \mu) \subseteq \text{Der}_S \). It thus remains to show that \( \Phi_\zeta \) is surjective. To this end, let \( \phi \in \mathcal{D}(\mathcal{A}, \nu + \mu) \). Since \( \mathcal{D}(\mathcal{A}, \nu + \mu) \subseteq \mathcal{D}(\mathcal{A}, \nu) \), we may write \( \phi = \nabla_\theta(\zeta) \) for some \( \theta \in \text{Der}_S \). We aim to show that \( \theta \in \mathcal{D}(\mathcal{A}, \mu) \). As in the proof of Lemma 3.8, we have
\[
\zeta(\alpha_H) = \alpha_H^{\mu(H)+1} f/Q_H
\]
for some \( f \in S \) and \( Q_H = (\frac{Q_H}{\alpha_H})^n \) with \( n \geq 0 \). Since \( \phi = \nabla_\theta(\zeta) \in \mathcal{D}(\mathcal{A}, \nu + \mu) \), we have
\[
(3.13) \quad \phi = \nabla_\theta(\zeta) = \frac{\alpha_H^{\mu(H)}}{Q_H^2} [(\nu(H) + 1)\theta(\alpha_H)fQ_H + \alpha_H(\theta(f)Q_H - f\theta(Q_H))] \in \alpha_H^{\mu(H)+\mu(H)} \cdot S_{(\alpha_H)}.
\]
Observe that Lemma 3.11 implies that \( f \notin \alpha_H \cdot S \) by the \( \nu \)-universality of \( \zeta \).

If \( \mu(H) = 0 \), there is no condition from (3.13) on \( \theta \), and so trivially \( \theta(\alpha_H) \in \alpha_H \cdot S = S \), and if \( \mu(H) = 1 \), then \( \theta(\alpha_H) \cdot f \in \alpha_H \cdot S \) implying that \( \theta(\alpha_H) \in \alpha_H \cdot S \), because \( f \) is not divisible by \( \alpha_H \), by (3.13). Consequently, \( \theta \in \mathcal{D}(\mathcal{A}, \mu) \), as desired. \( \square \)

4. A Hodge filtration and universality for reflection arrangements

For the remainder of the paper, we fix \( W \) to be a well-generated irreducible complex reflection group with reflection arrangement \( \mathcal{A} = \mathcal{A}(W) \), and the order multiplicity \( \omega : \mathcal{A} \to \mathbb{Z} \) given by \( \omega(H) = \epsilon_H \). Recall from (2.14) the flat system of derivations \( \eta_1, \ldots, \eta_{\ell} \). After having collected all necessary background material in Sections 2.2 and 2.3, we are now able to state and prove our main results. For \( 1 \leq j \leq \ell \) and \( k \in \mathbb{Z} \), define
\[
\xi_j^{(k)} := \nabla_j^k(\eta_j)
\]
and set
\[
\Xi^{(k)} := \{\xi_1^{(k)}, \ldots, \xi_\ell^{(k)}\} \quad \text{and} \quad \Xi := \bigcup_{k \in \mathbb{Z}} \Xi^{(k)}.
\]
Thanks to [HMRS19, (3.16)], we make the crucial observation that
\[
(4.1) \quad \xi_j^{(1)} = \partial_{\ell+1-j} \quad \text{for} \quad 1 \leq j \leq \ell.
\]
Theorem 4.2. Let $k \in \mathbb{Z}$. Then the following hold:

1. the $S$-module $\mathcal{D}(\mathcal{A}, -k\omega + 1)$ is free with basis $\Xi^{(k)}$,
2. the $R$-module $\mathcal{D}(\mathcal{R}, -k\omega + 1)^W$ is free with basis $\Xi^{(k)}$,
3. the $T$-module $\mathcal{D}(\mathcal{R}, -k\omega + 1)^W$ is free with basis $\bigcup_{p \leq k} \Xi^{(p)}$, and
4. the $T$-module $\mathcal{D}(\mathcal{R}, -\infty)^W$ is free with basis $\Xi$.

We prove this theorem in Section 4.1. It allows us to extend the Hodge filtration of $\text{Der}_R$ in (2.19) to a Hodge filtration of the $W$-invariant logarithmic vector fields $\mathcal{D}(\mathcal{R}, -\infty)^W$ given by the $T$-module

$$H^{(k)} := \bigoplus_{-\infty < i \leq k} \mathcal{G}_i$$

for $k \in \mathbb{Z}$, where $\mathcal{G}_i = \nabla^{-1}_D(\mathcal{G}_0)$ is as in (2.18). We record this in the following corollary.

Corollary 4.3. We have

$$\mathcal{D}(\mathcal{R}, -k\omega + 1)^W = H^{(k)} \quad \text{and} \quad \mathcal{D}(\mathcal{R}, -\infty)^W = \bigoplus_{k \in \mathbb{Z}} H^{(k)}$$

as $T$-modules and $\nabla_D$ induces $T$-linear isomorphisms

$$\nabla_D : H^{(k)} \rightarrow H^{(k+1)},$$

$$\nabla_D : \mathcal{D}(\mathcal{R}, -\infty)^W \rightarrow \mathcal{D}(\mathcal{R}, -\infty)^W.$$

Remark 4.4. In the real case, Theorem 4.2 and Corollary 4.3 are the main results of [AT10]. See in particular [AT10, Theorems 1.1 and 1.2] for these statements in the notion of logarithmic 1-forms, and [AT10, Theorems 3.7 and 3.9] for the statements in the notion as given here. For $k \leq 0$ the first property was also given in the real case in [Yos02, Cor. 10].

Remark 4.5. Denote by $\Omega(\mathcal{R}, \nu)$ the $S$-dual to $\mathcal{D}(\mathcal{R}, \nu)$ for a given multiplicity function $\nu$ induced by the fixed $W$-invariant Hermitian form. This is, $\Omega(\mathcal{R}, \nu)$ is the module of differential 1-forms with poles of order $\nu(H)$ along $H \in \mathcal{R}$, and $\Omega(\mathcal{R}, \infty)$ is the module of logarithmic 1-forms. If $W$ is a real reflection group, then it is known that

$$\Omega(\mathcal{R}, 1) \cong \mathcal{D}(\mathcal{R}, -\omega + 1) = \mathcal{D}(\mathcal{R}, -1)$$

as graded $S$-modules, see [AY09, Thm. 2]. It turns out that these modules are not isomorphic as graded $S$-modules if $W$ is not real. This follows from the observation that both $S$-modules are free, and the polynomial degrees of their homogeneous generators are

$$\exp(\mathcal{D}(\mathcal{R}, -\omega + 1)) = \{e_1^* - h, \ldots, e_\ell^* - h\} = \{-e_1, \ldots, -e_\ell\}$$

$$\exp(\Omega(\mathcal{R}, 1)) = \{-e_1, \ldots, -e_\ell\},$$

and the fact that

$$\{e_1, \ldots, e_\ell\} = \{e_1^*, \ldots, e_\ell^*\} \iff W \text{ is real}.$$

Armed with the universality properties obtained in Section 3.2, we obtain the freeness of $\mathcal{D}(\mathcal{R}, -k\omega)$ from Theorem 4.2(1) based on the universality of $\nabla^D_\partial(E)$ in Section 4.2.

Theorem 4.6. Let $k \in \mathbb{Z}$. The $S$-module $\mathcal{D}(\mathcal{R}, -k\omega)$ is free with basis

$$\{\nabla_{\partial e_1}(\xi_{1}^{(k)}), \ldots, \nabla_{\partial e_1}(\xi_{\ell}^{(k)})\}.$$
Theorem 4.7. Let $k \in \mathbb{Z}$. Then
\[
\mathcal{D}(\mathcal{A}, -k\omega)^W = \mathcal{D}(\mathcal{A}, -k\omega + 1)^W.
\]
In particular, $\mathcal{D}(\mathcal{A}, -k\omega)$ does not have a $W$-invariant basis.

Proof. Let $\theta \in \mathcal{D}(\mathcal{A}, -k\omega)^W$. Fix $H \in \mathcal{A}$ and let $\alpha_H = x_1, x_2, \ldots, x_\ell$ be an orthonormal basis of $V^*$. Write $\theta = \sum_i (f_i/Q^n_H) \partial_{x_i}$ with $f_i \in \alpha_H^{-k\omega} \cdot S$ and $f_i \in S$ for $2 \leq i \leq \ell$, as given in (3.3). Then $\theta(\alpha_H) = f_i/Q^n_H = \alpha_H^{-k\omega} g/Q^n_H$ with $g \in S$.

We aim to show that $g \in \alpha_H \cdot S$. To this end let $r \in \mathcal{R}$ be the reflection along $H$ and let $\epsilon$ be the $e_H$-th root of unity such that $r(\alpha_H) = e\alpha_H$.

Observe first that $r(Q_H) = Q_H$. This is because $Q_H = Q/\alpha_H$ so
\[
r(Q_H) = r(Q)/r(\alpha_H) = \epsilon Q/\epsilon \alpha_H = Q_H.
\]
This yields
\[
r(\theta(\alpha_H)) = \frac{r(\alpha_H^{-k\omega}) r(g)}{r(Q^n_H)} = \frac{\alpha_H^{-k\omega}}{Q^n_H} r(g).
\]
On the other hand,
\[
r(\theta(\alpha_H)) = (r\theta)(r(\alpha_H)) = e\theta(\alpha_H),
\]
since $\theta$ is $W$-invariant and we obtain $r(g) = \epsilon g$. With Lemma 2.5, we conclude $g \in \alpha_H \cdot S$ and $\theta \in \mathcal{D}(\mathcal{A}, -k\omega + 1)^W$.

The claim that $\mathcal{D}(\mathcal{A}, -k\omega)$ does not admit a $W$-invariant basis follows because
\[
\mathcal{D}(\mathcal{A}, -k\omega + 1) \subsetneq \mathcal{D}(\mathcal{A}, -k\omega),
\]
by Lemma 2.3. \hfill \Box

The proof of Theorem 4.7 indeed provides the following stronger result.

Corollary 4.8. Let $\nu$ be any $\mathbb{Z}$-valued multiplicity function on $\mathcal{A} = \mathcal{A}(W)$. For each $H \in \mathcal{A}$ choose $\alpha_H \in \mathbb{Z}$ so that $\mu : \mathcal{A} \to \mathbb{Z}$ defined by $\mu(H) := a_H e_H + 1$ satisfies $\mu - \omega < \nu \leq \mu$. Then
\[
\mathcal{D}(\mathcal{A}, \nu)^W = \mathcal{D}(\mathcal{A}, \mu)^W.
\]

4.1. Construction of the bases. We prove Theorem 4.2 in several steps.

Proposition 4.9. Let $k \in \mathbb{Z}$. The map
\[
\nabla_D : \mathcal{D}(\mathcal{A}, -k\omega + 1)^W \longrightarrow \mathcal{D}(\mathcal{A}, -(k+1)\omega + 1)^W
\]

is well-defined.

Proof. In symbols, the well-definedness of $\nabla_D$ means
\[
\theta \in \mathcal{D}(\mathcal{A}, -k\omega + 1)^W \implies \nabla_D(\theta) \in \mathcal{D}(\mathcal{A}, -(k+1)\omega + 1)^W.
\]
This is already known for $k < 0$ by [HMRS19, Thm. 3.22]. So we aim to show this for $k \geq 0$. Recall that $J = \prod_{i=1}^{k\omega - 1} x_i$. Let $H \in \mathcal{A}$ and consider an orthonormal basis $\alpha_H = x_1, x_2, \ldots, x_\ell$ of $V^*$. In this basis, for $\theta$ to belong to $\mathcal{D}(\mathcal{A}, -k\omega + 1)^W$ entails that there exist $f_1, \ldots, f_\ell \in S$ such that
\[
\theta = \sum_{i=1}^\ell f_i J^{-1} \partial_{x_i} \quad \text{and} \quad f_i \in x^{k\omega - 1}_i \cdot S \quad \text{for } 2 \leq i \leq \ell.
\]
Moreover,
\[
\nabla_D(\theta) = \sum_{i=1}^\ell D(f_i J^{-1}) \partial_{x_i}.
\]
Since
\[ \prod \alpha_{(k+1)\epsilon H}^{-1} D\left(f_1 J^{-1}\right) \in S, \]
it remains to show that
\[ g_i := \prod \alpha_{(k+1)\epsilon H}^{-1} D\left(f_1 J^{-1}\right) \in x_i^{(k+1)\epsilon H} \cdot S \]
for \(2 \leq i \leq \ell\). First, we see that \(g_i \in x_i^{\epsilon H} \cdot S\), because \(f_i \in x_i^{\epsilon H} \cdot S\) for \(2 \leq i \leq \ell\). On the other hand, observe that \(g_i\) is a relative invariant for det, cf. [OT92, Sec. 6.2]. This means in particular that
\[ s(g_i) = \det(s)(g_i), \]
where \(s = s_H \) is a reflection along \(H\) generating \(W_H\). This is because \(f_i J^{-1}\) is \(s\)-invariant by assumption on \(\theta\), \(D\) is \(W\)-invariant, and \(J\) is a relative invariant for det, see [OT92, Sec. 6.2]. Since \(s(\alpha_H) = \det^{-1}(s) \alpha_H\) and \(\det(s) = \det^{-1}(\epsilon H^{-1})(s)\), Lemma 2.5 implies that \(g_i \in x_i^{\epsilon H} \cdot S\) is indeed contained in \(x_i^{\epsilon H + (\epsilon H^{-1})} \cdot S\), as desired. \(\square\)

Recall the diagonal matrix \(B_\infty\) from (2.8) and the Saito matrix \(M_\eta\) of the system of flat derivations \(\eta_1, \ldots, \eta_\ell\) from (2.14).

**Proposition 4.10.** For \(k \geq 1\), we have
\[
(4.11) \quad \nabla_D^k \begin{pmatrix} \partial_{\ell_1} \\ \vdots \\ \partial_{\ell_\ell} \end{pmatrix} = -M_\eta^{-1}(B_\infty + k \mathbb{1}_\ell) \nabla_D^{k-1} \begin{pmatrix} \partial_{\ell_1} \\ \vdots \\ \partial_{\ell_\ell} \end{pmatrix}.
\]

**Proof.** We have already seen this to be true for \(k = 1\) in Proposition 2.17. We assume Equation (4.11) to hold for a given \(k\). Multiplying both sides of this equation by \(-M_\eta\) and applying \(\nabla_D\) gives
\[
(B_\infty + k \mathbb{1}_\ell) \nabla_D^k \begin{pmatrix} \partial_{\ell_1} \\ \vdots \\ \partial_{\ell_\ell} \end{pmatrix} = -\nabla_D \left( M_\eta \nabla_D^k \begin{pmatrix} \partial_{\ell_1} \\ \vdots \\ \partial_{\ell_\ell} \end{pmatrix} \right)
\]
\[= - \left( \nabla_D^k \begin{pmatrix} \partial_{\ell_1} \\ \vdots \\ \partial_{\ell_\ell} \end{pmatrix} + M_\eta \nabla_D^{k+1} \begin{pmatrix} \partial_{\ell_1} \\ \vdots \\ \partial_{\ell_\ell} \end{pmatrix} \right) \]
by the Leibniz rule and the fact that \(D(M_\eta) = \mathbb{1}_\ell\) in (2.15). This yields
\[
\nabla_D^{k+1} \begin{pmatrix} \partial_{\ell_1} \\ \vdots \\ \partial_{\ell_\ell} \end{pmatrix} = -M_\eta^{-1}(B_\infty + (k + 1) \mathbb{1}_\ell) \nabla_D^k \begin{pmatrix} \partial_{\ell_1} \\ \vdots \\ \partial_{\ell_\ell} \end{pmatrix},
\]
as desired. \(\square\)

**Corollary 4.12.** Let \(k \in \mathbb{Z}\). The set
\[
\{ \nabla_D^k(\partial_{\ell_1}), \ldots, \nabla_D^k(\partial_{\ell_\ell}) \}
\]
is linearly independent over \(S\).

**Proof.** This is already known for \(k < 0\) from [HMRS19, Prop. 3.18] and is trivially true for \(k = 0\). The case \(k > 0\) follows inductively from the previous proposition since \(-M_\eta^{-1}(B_\infty + k \mathbb{1}_\ell)\) is non-singular for all \(k\). Finally, the base change between \(R\) and \(S\) given by \(J_{\partial s_i/\partial t_i}\) is non-singular. \(\square\)
Proof of Theorem 4.2 (1) and (2). Proposition 4.9 and Corollary 4.12 allow us to apply our version of Saito’s criterion, Theorem 3.1. For this, it only remains to check that \( \sum_{i=1}^{\ell} \text{pdeg}(\nabla_D^{j}(\eta_i)) = | - k\omega + 1 | \). This follows from

\[
\sum_{i=1}^{\ell} \text{pdeg}(\nabla_D^{j}(\eta_i)) = \sum_{i=1}^{\ell} (k \text{pdeg}(D) - k + \text{pdeg}(\eta_i)) \\
= \sum_{i=1}^{\ell} (-kh + e_i) \\
= -k\ell h + |\mathcal{A}| = | - k\omega + 1 |,
\]

by (2.4), (2.7), and [OT92, Thm. 4.23]. \( \square \)

In order to prove Theorem 4.2 (3) and (4), it remains to show that the set given by \( \bigcup_{p \leq k} \Xi^{(p)} \) is \( T \)-independent and generates \( \mathfrak{D}(\mathcal{A}, -k\omega + 1)^W \) as a \( T \)-module.

**Proposition 4.13.** The set \( \Xi = \{ \xi_j^{(k)} \mid k \in \mathbb{Z}, 1 \leq j \leq \ell \} \) is \( T \)-independent.

**Proof.** Suppose \( \Xi \) is not \( T \)-independent. This means that there exist \( d \leq e \) and \( a_{kj} \in T \) with \( a_{dj}, a_{ek} \) not equal to zero for some \( 1 \leq j, k \leq \ell \) so that

\[
\sum_{k=d}^{e} \sum_{i=1}^{\ell} a_{ki} \xi_i^{(k)} = \sum_{k=d}^{e} (a_{k1}, \ldots, a_{k\ell})(\xi_1^{(k)}, \ldots, \xi_\ell^{(k)})^\text{tr} = 0.
\]

It follows from (4.11) that there is a non-singular matrix \( N_e \) so that

\[
\begin{pmatrix}
\begin{pmatrix}
\xi_1^{(e)} \\
\vdots \\
\xi_\ell^{(e)}
\end{pmatrix}&=\nabla_D
\begin{pmatrix}
\begin{pmatrix}
\partial_{t_1} \\
\vdots \\
\partial_{t_\ell}
\end{pmatrix}&=N_e
\begin{pmatrix}
\begin{pmatrix}
\partial_{t_1} \\
\vdots \\
\partial_{t_\ell}
\end{pmatrix}
\end{pmatrix}.
\end{pmatrix}
\]

Moreover, setting \( B_{k+1} = -(B_{\infty} + (k+1)1_\ell) \), we obtain

\[
B_{k+1}^{-1}M_\eta \nabla_D^{k+1} \begin{pmatrix}
\begin{pmatrix}
\partial_{t_1} \\
\vdots \\
\partial_{t_\ell}
\end{pmatrix}&=\nabla_D^k
\begin{pmatrix}
\begin{pmatrix}
\partial_{t_1} \\
\vdots \\
\partial_{t_\ell}
\end{pmatrix}
\end{pmatrix}.
\end{pmatrix}
\]

Recall from (2.14) that \( D[M_\eta] = 1_\ell \) and \( D[B_k] = 0 \) for all \( k \in \mathbb{Z} \), where the application of \( D \) to a matrix means its application to every entry of the matrix. Thus, the non-singular matrix \( H_k = B_{k+1}^{-1}M_\eta \cdots B_{e+1}^{-1}M_\eta B_{e}^{-1}M_\eta \) for \( d \leq k \leq e \) (with the convention that \( H_e = 1_\ell \)) yields

\[
\begin{pmatrix}
\xi_1^{(k)} \\
\vdots \\
\xi_\ell^{(k)}
\end{pmatrix} = H_k N_e \begin{pmatrix}
\begin{pmatrix}
\partial_{t_1} \\
\vdots \\
\partial_{t_\ell}
\end{pmatrix}&=\partial_{t_\ell}.\end{pmatrix}
\end{pmatrix}
\]

Given this description, (4.14) is equivalent to

\[
\sum_{k=d}^{e} (a_{k1}, \ldots, a_{k\ell}) H_k = 0,
\]

where we used that \( N_e \) is non-singular. Apply \( D^{e-d} \) and use that \( D^{e-k+1}(H_k) = 0 \) to obtain

\[
(a_{e1}, \ldots, a_{e\ell})B_{d+1}^{-1}D[M_\eta]B_{d+2}^{-1}D[M_\eta] \cdots B_{e}^{-1}D[M_\eta] = 0.
\]

Since \( D[M_\eta] = 1_\ell \), this implies \( (a_{e1}, \ldots, a_{e\ell}) = 0 \), a contradiction. \( \square \)
Proposition 4.15. With the notation as above, viewed as $T$-modules,

\[
\mathcal{D}(\mathcal{A}, -k\omega + 1)^W = \bigoplus_{\ell} \bigoplus_{p \leq k} T \cdot \xi^{(p)}_i.
\]

Proof. We know that the right hand side of (4.16) is a direct $T$-module summand of the space on the left by Proposition 4.13. It thus remains to show that the right hand side generates the left hand side. Owing to Theorem 4.2(2), we know that $\xi^{(k)}_1, \ldots, \xi^{(k)}_\ell$ form an $R$-basis for $\mathcal{D}(\mathcal{A}, -k\omega + 1)^W$. Thus it suffices to show that the right hand side is an $R$-module. We know this is true if $k \leq 0$ by [HMRS19, Thm. 3.22] and proceed by induction on $k \geq 0$. From

\[
\nabla_D(t_\ell \cdot (\xi^{(k)}_1, \ldots, \xi^{(k)}_\ell)) = D(t_\ell) \cdot (\xi^{(k)}_1, \ldots, \xi^{(k)}_\ell) + t_\ell \cdot (\xi^{(k+1)}_1, \ldots, \xi^{(k+1)}_\ell),
\]

we obtain

\[
t_\ell \cdot (\xi^{(k+1)}_1, \ldots, \xi^{(k+1)}_\ell) = \nabla_D(t_\ell \cdot (\xi^{(k)}_1, \ldots, \xi^{(k)}_\ell)) - (\xi^{(k)}_1, \ldots, \xi^{(k)}_\ell).
\]

By induction hypothesis, we have

\[
t_\ell \xi^{(k)}_j \in \bigoplus_{p \leq k} \bigoplus_{i=1}^\ell T \cdot \xi^{(p)}_i
\]

for $1 \leq j \leq \ell$, and thus

\[
\nabla_D(t_\ell \xi^{(k)}_j) \in \nabla_D \left( \bigoplus_{p \leq k} \bigoplus_{i=1}^\ell T \cdot \xi^{(p)}_i \right) = \bigoplus_{p \leq k} \bigoplus_{i=1}^\ell T \cdot \nabla_D(\xi^{(p)}_i) = \bigoplus_{p \leq k+1} \bigoplus_{i=1}^\ell T \cdot \xi^{(p)}_i.
\]

We deduce that for every $1 \leq j \leq \ell$, we get

\[
t_\ell \xi^{(k+1)}_j \in \bigoplus_{p \leq k+1} \bigoplus_{i=1}^\ell T \cdot \xi^{(p)}_i
\]

to complete the proof. \(\square\)

Proof of Theorem 4.2 (3) and (4). Propositions 4.13 and 4.15 immediately give statement (3). Finally, (4) follows, because every element in $\mathcal{D}(\mathcal{A}, -\infty)^W$ is contained in $\mathcal{D}(\mathcal{A}, -k\omega + 1)^W$ for some $k \in \mathbb{Z}$. \(\square\)

4.2. Universal vector fields for reflection arrangements. In this final section, we conclude the universality properties for reflection arrangements.

Our first result generalizes [Wak11, Prop. 2.5] to the complex case, and in particular, it implies Theorem 4.6. Recall the Euler derivation $E$ from (2.16).

Theorem 4.17. With the notation as above, $\nabla_D(E)$ is $(-k\omega)$-universal for any $k \in \mathbb{Z}$.

Proof. For $k \leq 0$, this is the special case of [HMRS19, Thm. 3.20] for $\theta_i = \partial_{x_i}$. It remains to consider the case $k \geq 0$. Set $E_k := \nabla_D(E)$. By Proposition 4.9, we have that $E_k \in \mathcal{D}(\mathcal{A}, -k\omega + 1)$ which in turn implies that $\Phi_{E_k} : \text{Der}_S \to \mathcal{D}(\mathcal{A}, -k\omega)$ is well-defined, by Lemma 3.8. Moreover, the $S$-independence of $\{\nabla_{\partial_{x_i}}(E_k) \mid 1 \leq i \leq \ell\}$ follows from the $R$-independence of $\{\nabla_{\partial_{x_i}}(E_k) \mid 1 \leq i \leq \ell\}$ proven in Theorem 4.2(2) and (4.1). Here, we used that $\nabla_\partial_{x_i} \nabla_\partial_{x_j} = \nabla_\partial_{x_j} \nabla_\partial_{x_i}$ and that $\nabla_\partial_{x_i}(E) = \frac{1}{h} \partial_{x_i}$. Finally, we deduce that $\{\nabla_{\partial_{x_i}}(E_k) \mid 1 \leq i \leq \ell\}$ is an $S$-basis of $\mathcal{D}(\mathcal{A}, -k\omega)$ from the version of the Saito criterion.
given in Theorem 3.1(iii). In the later, we remark that indeed \( \nabla_{\partial x_i}(E_k) \) is homogeneous, since \( E_k \) is homogeneous (cf. (2.11)), and so we obtain
\[
\sum \text{pdeg} (\nabla_{\partial x_i}(E_k)) = \sum (-kh + \text{pdeg}(\partial x_i)) = -k\ell h = | -k\omega|,
\]
again by (2.4), (2.7), and [OT92, Thm. 4.23].

The following properties are the complex counterparts of the results in [Wak11, Sec. 2], where we remark that the arguments are similar. Recall the order multiplicity \( \omega : \mathcal{A} \to \mathbb{Z} \) on the reflection arrangement \( \mathcal{A} \) given by \( \omega(H) = e_H \). Our aim here is to generalize Theorem 3.12 to multiplicity functions \( \mu : \mathcal{A} \to \mathbb{Z} \) with \( -\omega + 1 \leq \mu \leq 1 \).

**Proposition 4.18.** Let \( \nu \) be any \( \mathbb{Z} \)-valued multiplicity on \( \mathcal{A} \) and let \( \zeta \in \mathcal{D}(\mathcal{A}, -\infty)^W \) be \( \nu \)-universal. Then
\[
\Phi_\zeta : \mathcal{D}(\mathcal{A}, -\omega + 1) \to \mathcal{D}(\mathcal{A}, \nu - \omega + 1)
\]
is an isomorphism of \( S \)-modules.

**Proof.** We have seen in Theorem 4.2(1) that \( \{\partial_{t_1}, \ldots, \partial_{t_\ell}\} \) is an \( S \)-basis of \( \mathcal{D}(\mathcal{A}, -\omega + 1) \). We thus aim to show that \( \{\nabla_{\partial_{t_1}}\zeta, \ldots, \nabla_{\partial_{t_\ell}}\zeta\} \) is an \( S \)-basis of \( \mathcal{D}(\mathcal{A}, \nu - \omega + 1) \).

It is immediate from (2.12) that \( J\partial_{t_i} \in \text{Der}_S \). This implies \( J\nabla_{\partial_{t_i}}\zeta \in \mathcal{D}(\mathcal{A}, \nu) \) by the linearity of \( \nabla \) in the first parameter and the \( \nu \)-universality of \( \zeta \). Thus we have that
\[
J(\nabla_{\partial_{t_i}}\zeta)(\alpha_H) \in \alpha_H^{\nu(H)}S(\alpha_H)
\]
or, equivalently,
\[
(\nabla_{\partial_{t_i}}\zeta)(\alpha_H) \in \alpha_H^{\nu(H)-(\nu(H)-1)}S(\alpha_H)
\]
for a given \( H \in \mathcal{A} \). Now let \( \alpha_H = x_1, x_2, \ldots, x_\ell \) be an orthonormal basis of \( V^* \) and for \( 2 \leq i \leq \ell \) set
\[
g_i = Q_H^N J(\nabla_{\partial_{t_i}}\zeta)(x_i) \in S,
\]
for some \( N \geq 0 \), where \( Q_H = Q/\alpha_H \). Analogous to the argument in the proof of Proposition 4.9, we obtain that \( g_i \in \alpha_H^{\nu(H)-1}S \), and so
\[
(\nabla_{\partial_{t_i}}\zeta)(x_i) = Q_H^{-N} g_i J^{-1} \in S(\alpha_H),
\]
for \( 2 \leq i \leq \ell \). We thus have \( \nabla_{\partial_{t_i}}\zeta \in \mathcal{D}(\mathcal{A}, \nu - \omega + 1) \). Computing
\[
\det ( (\nabla_{\partial_{t_i}}\zeta)(x_i) ) = J^{-1} \det ( (\nabla_{\partial_{t_i}}\zeta)(x_i) ) = J^{-1}Q_\nu = Q_\nu - \omega + 1
\]
yields the statement, thanks to Theorem 3.1. \( \square \)

**Theorem 4.19.** Let \( \zeta \in \mathcal{D}(\mathcal{A}, -\infty)^W \) be \( \nu \)-universal for a \( \mathbb{Z} \)-valued multiplicity function \( \nu \) on \( \mathcal{A} \). Let \( \mu : \mathcal{A} \to \mathbb{Z} \) be a multiplicity with \( -\omega + 1 \leq \mu \leq 1 \). Then
\[
\Phi_\zeta : \mathcal{D}(\mathcal{A}, \mu) \to \mathcal{D}(\mathcal{A}, \nu + \mu)
\]
is an isomorphism of \( S \)-modules. In particular, \( \mathcal{D}(\mathcal{A}, \mu) \) is free if and only if \( \mathcal{D}(\mathcal{A}, \nu + \mu) \) is free.

Before proving Theorem 4.19, we use the fact that \( \zeta = \nabla_D^{-m}(E) \) is \((m\omega)\)-universal for any \( m \in \mathbb{Z} \), by Theorem 4.17 to obtain the special case of the generalized Ziegler multiplicity on a reflection arrangement \( \mathcal{A} \) given by \( m\omega - 1 \) for \( m \in \mathbb{Z} \). For \( m = 1 \), this multiplicity was originally considered by Ziegler [Zie89] (assigning the number of reflections along \( H \) to any reflecting hyperplane), and shown to be free in general in [Zie89] and [HR14].
Corollary 4.20. Let \( \{e_1, \ldots, e_\ell\} \) be the set of exponents of \((\mathcal{A}, \omega - 1)\). For any \( m \in \mathbb{Z} \), the multi-arrangement \((\mathcal{A}, m\omega - 1)\) is free and its exponents are given by
\[
\{ e_1 + (m-1)h, \ldots, e_\ell + (m-1)h \}.
\]

Proof of Theorem 4.19. As \( \mathcal{D}(\mathcal{A}, \mu) \subseteq \mathcal{D}(\mathcal{A}, -\omega + 1) \) and \( \mathcal{D}(\mathcal{A}, \nu + \mu) \subseteq \mathcal{D}(\mathcal{A}, \nu - \omega + 1) \), Proposition 4.18 implies that \( \Phi_\zeta \) is injective on \( \mathcal{D}(\mathcal{A}, \mu) \). It thus remains to show that
\[
(\Phi_\zeta)(\mathcal{D}(\mathcal{A}, \mu)) = \mathcal{D}(\mathcal{A}, \nu + \mu).
\]

Fix \( H \in \mathcal{A} \) and let \( \alpha_H = x_1, x_2, \ldots, x_\ell \) be an orthonormal basis of \( V^* \). The element \( g = \alpha_H^{-\nu(H)-1}\zeta(\alpha_H) \in S(\alpha_H) \) is a unit in \( S(\alpha_H) \), by Lemma 3.11. For \( \theta \in \mathcal{D}(\mathcal{A}, -\infty) \), compute
\[
(\Phi_\zeta(\theta))(\alpha_H) = \theta(\alpha_H^{\nu(H)+1} g) \]  
\[
= \alpha_H^{\nu(H)+1} \theta(g) + (\nu(H) + 1) \alpha_H^{\nu(H)} \theta(\alpha_H) g \]  
\[
= \alpha_H^{\nu(H)} \theta(\alpha_H) (\alpha_H \frac{\partial}{\partial x_H} + (\nu(H) + 1)g) + \alpha_H^{\nu(H)+1} \sum_{i=2}^{\ell} \theta(x_i) \frac{\partial}{\partial x_i} \]  
\[
= \alpha_H^{\nu(H)} \theta(\alpha_H) U + \alpha_H^{\nu(H)+1} C,
\]
where \( U = \alpha_H \frac{\partial}{\partial x_H} + (\nu(H) + 1)g \) is again a unit in \( S(\alpha_H) \) and \( C = \sum_{i=2}^{\ell} \theta(x_i) \frac{\partial}{\partial x_i} \). Note that \( C \in S(\alpha_H) \), since \( \theta \in \mathcal{D}(\mathcal{A}, -\infty) \), and so is \( \alpha_H^{1-\nu(H)} C \). We thus obtain
\[
\alpha_H^{-\nu(H)-\nu(H)}(\Phi_\zeta(\theta))(\alpha_H) = \alpha_H^{-\nu(H)} \theta(\alpha_H) U + \alpha_H^{1-\nu(H)} C,
\]
implying that
\[
(\Phi_\zeta(\theta))(\alpha_H) \in \alpha_H^{\nu(H)+\nu(H)} S(\alpha_H) \iff \theta(\alpha_H) \in \alpha_H^{\nu(H)} S(\alpha_H).
\]

Since this holds for any \( H \in \mathcal{A} \), the reverse implication shows the containment \( "\subseteq" \) in (4.21) and the forward implication the containment \( "\supseteq" \). \( \square \)

We finally conclude the extension of [Wak11, Thm. 2.8] to the unitary setting.

Theorem 4.22. Let \( \zeta \in \mathcal{D}(\mathcal{A}, -\infty) \) and let \( k \in \mathbb{Z} \). Then
\[
\zeta \text{ is } (k\omega)\text{-universal} \implies \nabla_D^{-1} \zeta \text{ is } ((k+1)\omega)\text{-universal}.
\]

Proof. We set \( \nu = k\omega \) in the proof for better readability. Let \( \eta_1, \ldots, \eta_\ell \in \mathcal{D}(\mathcal{A}, 1)^W \) be an \( S \)-basis. Due to the universality of \( \zeta \), we also have that \( \nabla_{\eta_i} \zeta, \ldots, \nabla_{\eta_\ell} \zeta \in \mathcal{D}(\mathcal{A}, \nu + 1)^W \) form an \( S \)-basis. Since \( \nu \) is a multiple of \( \omega \), we also have that
\[
\nabla_D \nabla_{\eta_i} \zeta \in \mathcal{D}(\mathcal{A}, \nu + 1 - \omega)^W.
\]

Because the \( \partial_{ij} \in \mathcal{D}(\mathcal{A}, -\omega + 1)^W \) form an \( S \)-basis as well, we obtain
\[
\nabla_D \nabla_{\eta_i} \zeta = \sum_i f_{ij} \nabla_{\eta_i} \zeta
\]
for \( W \)-invariant polynomials \( f_{ij} \). Comparing polynomial degrees yields \( \deg f_{ij} = e_i + e_j^* - h < h \) (or, respectively, \( f_{ij} = 0 \) for \( e_i + e_j^* < h \)) which shows that \( f_{ij} \in T \). Moreover, \( \deg f_{i,\ell+1-i} = e_i + e_{\ell+1-i}^* - h = 0 \) for all \( 1 \leq i \leq \ell \), and it follows that \( \det f_{ij} \in \mathbb{C} \). Applying \( \nabla_D^{-1} \) gives
\[
\nabla_{\eta_i} \zeta = \sum_i f_{ij} \nabla_{\partial_i} \nabla_D^{-1} \zeta.
\]
Because the vector fields on the left form an $S$-basis of $\mathcal{D}(\mathcal{A}, \nu + 1)$, we readily see that $\det f_{ij} \neq 0$ and the $\nabla_{\partial_i} \nabla_D^{-1} \zeta \in \mathcal{D}(\mathcal{A}, \nu + 1)^W$ form an $S$-basis. Again, because $\nu$ is a multiple of $\omega$, we have $\nabla_D^{-1} \zeta \in \mathcal{D}(\mathcal{A}, \nu + 1 - \omega)^W$ and we see that the derivations

$$\nabla_{\partial_j} \nabla_D^{-1} \zeta = \sum_i J_{\partial i/\partial x} \nabla_{\partial_j} \nabla_D^{-1} \zeta$$

form an $S$-basis of $\mathcal{D}(\mathcal{A}, \nu + \omega)$ by Saito’s criterion. □

Acknowledgments. We thank the referees for their helpful comments clarifying some points.
