If two particles moving towards a black hole collide near the horizon, their energy in the centre of mass frame can grow unbounded. This is the so-called Banados - Silk - West (BSW) effect. Earlier, it was shown that in the 3+1 space-time this effect has a universal nature. We show that for a wide class of many-dimensional black holes (including, say, the Myers-Perry black hole) this is also true. The suggested analysis is general and does not require special properties of the metric like separability of variables for geodesics, etc.

I. INTRODUCTION

In 2009, Bañados, Silk and West made an interesting observation [1]. It turned out that if two particles collide near the extremal Kerr black hole, the energy in the centre of mass frame can grow unbounded (the BSW effect, called after the names of its authors). Later on, the BSW effect was extended to generic extremal and nonextremal stationary axially-symmetric black holes, charged static black holes, black holes in the magnetic field, etc. One of separate issues provoking special interest is the possibility of generalization to the many-dimensional case. It was demonstrated in [2] for the five-dimensional Kerr metric and in [3] for many-dimensional Myers-Perry black hole [4] that the BSW effect does exist. It required

*Electronic address: zaslav@ukr.net.*
rather developed studies, especially in [3], where very subtle properties of motion in the Myers-Perry black hole background were exploited, including the separability of variables [4] - [6].

One may ask: whether the BSW effect for a Myers-Perry black hole arises due to some special properties of this very space-time? If so, one would be led to incremental inspection of different models step by step. However, it is worth reminding that it was shown earlier that for 3+1 black holes the BSW effect is of universal nature [7], [8] and is due to the existence of the horizon as such, independently of a particular model. Therefore, a natural supposition arises that the situation is similar in a many-dimensional case. In the 3+1 space-time, the BSW effect requires the existence of so-called critical trajectories with fine-tuned parameters. Then, it is produced by collision between such a fine-tuned ("critical") particle and generic ("usual") one. However, both the overall approach and the formulation of critical condition are so different in [2], [3] and in [7], [8], that the issue of universality is not obvious in advance.

The aim of the present paper is to show that there exists deep continuity between 3+1 and higher-dimensional cases. And, the approach to the BSW effect can be formulated in such a way that, without relying on special properties of space-time like separability of variables, etc., one can obtain the critical condition and the effect under discussion as direct generalization of the 3+1 case.

Throughout the paper we use units in which fundamental constants are $G = c = 1$.

II. BASIC EQUATIONS

We consider the metric

$$ds^2 = -dt^2 + \frac{dr^2}{A(r, \theta)} + \rho^2 d\theta^2 + \sum_{i=1}^{n} g_i(\{\alpha_k\}, \theta, r) d\phi_i^2 + B(r, \theta)[dt - \sum_{i=1}^{n} b_i(\{\alpha_k\}, d\phi_i)]^2 + \sum_{i=1}^{n} A_i(\{\alpha_k\}, \theta, r) d\alpha_i^2.$$  

(1)

Here, the variable $\theta$ is singled by analogy with the 3+1 case and to make comparison to the many-dimensional Myers-Perry black hole [3] more convenient. We assume that all the metric coefficients do not depend on $t$ and $\phi_i, i = 1, ... n$. Although the metric (1), with these restrictions, is not the most general one, it includes physically important space-times, in particular, the aforementioned Myers-Perry black hole. On the horizon, $N^2 = 0$. 
The metric can be rewritten in the form which is more familiar, especially from the 3+1 context:

\[ ds^2 = -N^2 dt^2 + \sum_{i=1}^{n} h_{ij}(d\phi^i - \omega^i dt)(d\phi^j - \omega^j dt) + \frac{dr^2}{A} + g_\theta d\theta^2 + \sum_{i=1}^{n} A_i d\alpha_i^2. \]  

(2)

The relationship between two forms of the metric are given by obvious formulas

\[ -N^2 + \sum_k h_{ij} \omega^i \omega^j = B - 1 \]  

(3)

\[ Bb_i = h_{ij} \omega^j, \quad Bb_i b_j = h_{ij}. \]  

(4)

The inverse metric is equal to

\[ g^{00} = -\frac{1}{N^2}, \quad g^{rr} = A, \quad g^{\theta\theta} = \frac{1}{g_\theta}, \quad g^{\phi i} = -\frac{\omega_i}{N^2}, \quad g^{\alpha_k \alpha_k} = \frac{1}{A_k}, \]  

(5)

\[ g^{ik} = h^{ik} - \frac{\omega^i \omega^k}{N^2}, \]  

(6)

where \( h^{ij} h_{jk} = \delta^i_k \).

As the metric does not depend on time, the energy \( E = -mu_0 \) is conserved (\( m \) is a mass), the velocity \( u^\alpha = \frac{dx^\alpha}{d\tau} \), where \( \tau \) is the proper time. In a similar way, there are conserved angular momenta corresponding to variables \( \phi_i, \mu_i = L_i \). Then, the equations of motion for geodesics read (dot denotes differentiation with respect \( \tau \)):

\[ m \dot{t} = \frac{X}{N^2}, \]  

(7)

\[ X = E - \sum_k \omega^k L_k, \]  

(8)

\[ m \dot{\phi}^i = h^{ij} L_j + \frac{\omega^i X}{N^2}. \]  

(9)

Using the normalization condition \( u_\alpha u^\alpha = -1 \), we obtain the equation for the radial component. Then, we have

\[ m \dot{r}^2 = \frac{A}{N^2} Z^2, \]  

(10)

\[ Z^2 = X^2 - N^2(\sum_k h^{ij} L_i L_j + m^2 + \sum_k A_k \alpha_k^2). \]  

(11)
III. COLLISION OF TWO PARTICLES

If two particles 1 and 2 collide, one can define their energy in the centre of mass frame in the point of collision according to

\[ E_{c.m.}^2 = -(m_1u_1^\mu + m_2u_2^\mu)(m_1u_{1\mu} + m_2u_{2\mu}) = m_1^2 + m_2^2 + 2m_1m_2\gamma, \] (12)

where the Lorentz factor of relative motion equals

\[ \gamma = -u_1^\mu u_2^\mu. \] (13)

Then, it follows from the equations of motion (7) - (11) that

\[ \gamma = \frac{X_1X_2 - Z_1Z_2}{m_1m_2N^2} - \sum_k h^{ij}L_{1i}L_{2j} - \sum_k A_k\dot{\alpha}_{1k}\dot{\alpha}_{2k}. \] (14)

We do not specify the character of motion and only require that \( \dot{\alpha}_{1k} \) and \( \dot{\alpha}_{2k} \) be finite. In particular, there exist simplest geodesics with all \( \alpha_k = const. \)

Let the point of collision be close to the horizon. In general, this does not lead to the growth of \( \gamma \) since the numerator in \( \gamma \) vanishes with the same rate as the denominator. However, there is an exception. Let us call a particle usual if \( X^H \neq 0 \) and critical if \( X^H = 0 \) (subscript ”H” means that the quantity is calculated on the horizon). According to (8), the condition of criticality reads

\[ E = \sum_k (\omega^k)_H L_k. \] (15)

Let the critical particle 1 and a usual particle 2 collide near the extremal horizon. Now, we need the behavior of \( X \) near the horizon. We restrict ourselves by the extremal case, similarly to what was done in [3] for Myers-Perry black holes. Then, we can exploit the Taylor expansion near the horizon:

\[ \omega^k = \omega^k_H - \omega^k_H N + O(N^2), \] (16)

where \( \omega_1 \) does not depend on \( r \). (For more general discussion of expansions of this kind for nonextremal and extremal horizons 3+1 dimensional see Ref. [9]. Extension of its results to the many-dimensional case is straightforward). By substitution into (8) and taking eq. (16) into account, we obtain that near the horizon

\[ X = CN + O(N^2), \] (17)
where \( C = \sum_k \omega_k^i L_k \).

Then, it follows from (14) that near the horizon

\[
\gamma \approx \frac{X_2D}{Nm_1m_2}, \quad D = C - \sqrt{C^2 - \left( \sum_k \hbar \omega_k^i L_i L_j + m^2 + \sum_k A_k \dot{\omega}_k^2 \right) H}.
\] (18)

Thus for \( N \to 0 \) the factor \( \gamma \) grows unbounded, and we have the BSW effect.

IV. CONCLUSION

Thus we have shown in a very simple and direct manner that the general approach to the BSW effect developed earlier for 3+1 black holes \cite{1}, \cite{2}, works, with some modifications, also in a many-dimensional case. The key ingredients are preserved: (i) the presence of the horizon, (ii) classification of particles according to which one of them should be critical, another one should be usual. In the particular case of the Myers-Perry black hole, the condition of criticality \cite{15} corresponds to eq. (2.30) of \cite{3}. As long as we are interested in the BSW effect as such, there is no need in examining new models one after another and elucidating complicated and subtle details of particles’ motion (which, of course, can be of interest by themselves). If the metric belongs to the class \cite{1}, \cite{2}, the existence of the BSW effect follows from general grounds.

The general character of our treatment enables us also to use (directly or with minimum modifications) some other results concerning properties of the BSW effect. For instance, classification of the possible types of the BSW scenarios suggested in Sec. 6 of Ref. \cite{8} now applies and is insensitive to the number of dimensions. It includes as particular cases the 3+1 Kerr metric (see Sec. IV A of Ref. \cite{10}) and the Myers-Perry black hole \cite{3}.

Actually, we showed that the persistence of the BSW effect can be considered as one more manifestation of universality typical of black holes physics. This can have interesting physical consequences like, for example, instability of extremal horizons \cite{3} but this issue requires separate treatment.
