Abstract
We study stochastic Navier–Stokes equations in two dimensions with respect to periodic boundary conditions. The equations are perturbed by a nonlinear multiplicative stochastic forcing with linear growth (in the velocity) driven by a cylindrical Wiener process. We establish convergence rates for a finite-element based space-time approximation with respect to convergence in probability (where the error is measured in the \(L^\infty_t L^2_x \cap L^2_t W^{1,2}_x\)-norm). Our main result provides linear convergence in space and convergence of order (almost) \(1/2\) in time. This improves earlier results from Carelli and Prohl (SIAM J Numer Anal 50(5):2467–2496, 2012) where the convergence rate in time is only (almost) \(1/4\). Our approach is based on a careful analysis of the pressure function using a stochastic pressure decomposition.

1 Introduction

In this paper we are concerned with the stochastic Navier–Stokes equations

\[
\begin{align*}
\frac{d\mathbf{u}}{dt} &= \mu \Delta \mathbf{u} \, dt - (\nabla \mathbf{u}) \mathbf{u} \, dt - \nabla \pi \, dt + \Phi(\mathbf{u}) \, dW \quad \text{in } Q, \\
\text{div} \mathbf{u} &= 0 \quad \text{in } Q, \\
\mathbf{u}(0) &= \mathbf{u}_0 \quad \text{in } \mathcal{O},
\end{align*}
\]

(1.1)
on a filtered probability space \((\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, P)\). The equations are perturbed by an \((\mathcal{F}_t)\)-Wiener process (possibly infinite dimensional) and \(\Phi\) grows linearly in \(\mathbf{u}\) (see Sect. 2.1 for the precise assumptions). The quantity \(\mu > 0\) is the viscosity of the fluid.
and $\mathbf{u}_0$ is a given (random) initial datum. Here the unknowns are the velocity field $\mathbf{u} : \Omega \times Q \to \mathbb{R}^N$ and the pressure $\pi : \Omega \times Q \to \mathbb{R}$, where $Q = (0, T) \times \mathcal{O}$ and $\mathcal{O} \subset \mathbb{R}^N$ with $N = 2, 3$.

The stochastic perturbation in the balance of momentum (1.1) can take into account physical, empirical or numerical uncertainties and thermodynamical fluctuations. In addition to that, a main reason why the stochastic Navier–Stokes equations (1.1) became so popular in fluid mechanical research is their application to turbulence theory (see, for instance, [2,21]). Its mathematical investigation started in the 70’s with the pioneering paper of Bensoussan and Temam [1]. They provide a semi-deterministic approach based on the flow-transformation. A first fully stochastic theory has been developed by Flandoli and Gatarek [14] by showing the existence of a martingale solution. These solutions are weak in the stochastic sense meaning that the underlying probability space as well the Wiener process $W$ are not a priori known but become an integral part of the solution. In two dimensions, when uniqueness is known, a stochastically strong solution exists (it is defined on a given probability space with a given Wiener process), see [12]. Nowadays there is a huge amount of literature concerning the analysis of (1.1) and most of the results from the deterministic theory found their stochastic counterpart. For an overview we refer to the recent survey article [25].

The situation about the numerical approximation of (1.1) is totally different and only very few results are available. In [8] a fully practical space-time approximation for the three-dimensional stochastic Navier–Stokes equations in a bounded domain is studied. It is shown that the sequence of approximate solutions converges in law (up to a subsequence) to a martingale solution if both discretization parameters tend to zero. This is the best result one can hope for without using some unproven hypotheses about the space-regularity of solutions (or to be content with local-in-time results). In two dimensions the situation is much better, at least if periodic boundary conditions are considered, that is

$$
\mathcal{O} = \mathbb{T}^2 = \left((-\pi, \pi) \cup (-\pi, \pi) \right)^2.
$$

The space-regularity of the unique strong solution is well-known (see for instance [20]). Based on this the convergence rates for a finite-element based space-time approximation is analysed in [9]. The result is linear convergence in space and convergence of order (almost) 1/4 in time. The precise estimate comparing the solution $\mathbf{u}$ and its space-time approximation $\mathbf{u}_{h,m}$ reads as

$$
\mathbb{E}\left[ \mathbf{1}_{\Omega_{\Delta t,h}} \left( \max_{1 \leq m \leq M} \| \mathbf{u}(t_m) - \mathbf{u}_{h,m} \|_{L_2}^2 + \sum_{m=1}^{M} \Delta t \| \nabla \mathbf{u}(t_m) - \nabla \mathbf{u}_{h,m} \|_{L_2}^2 \right) \right] \leq c \left( h^2 + (\Delta t)^{2\alpha} \right)
$$

for any $\alpha < 1/4$. Here we have $\Omega_{\Delta t,h} \subset \Omega$ with $\mathbb{P}(\Omega \setminus \Omega_{\Delta t,h}) \to 0$ as $\Delta t, h \to 0$. Consequently, one can infer from (1.2) convergence in probability (as defined by Printems [24]) with asymptotic rates (almost) 1/4 and 1 respectively. The aim of
the present paper is to improve the convergence rates in time from (almost) $1/4$ to (almost) $1/2$, see Theorem 3 for the precise statement. This is certainly the optimal convergence rate in time in view of the stochastic forcing and should also be considered as the natural result because of the space-regularity of the solution.

The reason for the low convergence rate in time in [9] is the low time-regularity of the pressure function $\pi$ in (1.1). Its appearance can only be avoided when working with finite element functions which are exactly divergence-free. Unfortunately, their construction is quite complicated such that the preferred discretizations (such as the Taylor–Hood, the Crouzeix–Raviart, and the MINI element, see [7,16,17]) are only asymptotically divergence-free. The low regularity of the pressure gradient arises from the stochastic forcing (in fact, $\nabla \pi$ behaves as $dW$) and improvements do not seem possible unless the noise is divergence-free (this is quite restrictive as it only allows certain additive or linear multiplicative noise). In the general case (non-divergence-free finite elements and nonlinear multiplicative noise) a more subtle analysis of the pressure function is required. Our main idea is a decomposition of the pressure into a deterministic and a stochastic component (such a decomposition first appeared in [5]). The deterministic pressure part behaves as the convective term $u \otimes u$. The latter one can be estimated along the lines of [9] (following classical deterministic arguments combined with a discrete stopping time). In addition a second stochastic integral appears which behaves similarly to the original stochastic integral. Although the time-regularity of this noise has not improved, we benefit from the averaging properties of the Itô-integral. Combining these ideas finally leads to the optimal convergence rate in Theorem 3.

The paper is organized as follows. In Sect. 2 we present the mathematical framework, that is the probability setup, the concept of solutions and their qualitative properties. In particular, we give improved (compared to [9]) results on the time-regularity of $\nabla u$, see Corollary 2 b). This is needed in Sect. 3 in order to estimate the error between the continuous solution and the time-discrete solution. The heart of the paper is Sect. 4 where we estimate the error between the time-discrete solution and the space-time discretization. Crucial tools are the space-regularity of the time-discrete solution from [8] and the decomposition of the corresponding pressure function.

## 2 Mathematical framework

### 2.1 Probability setup

Let $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$ be a stochastic basis with a complete, right-continuous filtration. The process $W$ is a cylindrical Wiener process, that is, $W(t) = \sum_{k \geq 1} \beta_k(t) e_k$ with $(\beta_k)_{k \geq 1}$ being mutually independent real-valued standard Wiener processes relative to $(\mathcal{F}_t)$ and $(e_k)_{k \geq 1}$ is a complete orthonormal system in a separable Hilbert space $\mathcal{H}$. To give the precise definition of the diffusion coefficient $\Phi$, consider $z \in L^2(\mathbb{T}^2)$ and let $\Phi(z) : \mathcal{H} \rightarrow L^2(\mathbb{T}^2)$ be defined by $\Phi(z)e_k = g_k(\cdot, z(\cdot))$. In particular, we suppose that $g_k \in C^1(\mathbb{T}^2 \times \mathbb{R}^2)$ and that the following conditions hold:
\[
\sum_{k \geq 1} |g_k(x, \xi)|^2 \leq c(1 + |\xi|^2), \quad \sum_{k \geq 1} |\nabla_x g_k(x, \xi)|^2 \leq c, \quad x \in \mathbb{T}^2, \ \xi \in \mathbb{R}^2.
\]

If we are interested in higher regularity some further assumptions are in place and we require additionally \( g_k \in C^2(\mathbb{T}^2 \times \mathbb{R}^2) \) together with
\[
\sum_{k \geq 1} |\nabla^2_x g_k(x, \xi)|^2 \leq c(1 + |\xi|^2), \quad \sum_{k \geq 1} |\nabla^2_\xi g_k(x, \xi)|^2 \leq \frac{c}{1 + |\xi|^2},
\]
\[
\sum_{k \geq 1} |\nabla_x \nabla^2_\xi g_k(x, \xi)|^2 \leq c, \quad x \in \mathbb{T}^2, \ \xi \in \mathbb{R}^2.
\]

We remark that the first inequality of (2.1) implies
\[
\|\Phi(u)\|_{L^2(U; L^2_x)} \leq c(1 + \|u\|_{L^2_x}) \quad \forall u \in L^2(\mathbb{T}^2),
\]
all inequalities from (2.1) imply
\[
\|\Phi(u)\|_{L^2(U; W^{1,2}_x)} \leq c(1 + \|u\|_{W^{1,2}_x}) \quad \forall u \in W^{1,2}(\mathbb{T}^2),
\]
and (2.1) finally yields
\[
\|\Phi(u)\|_{L^2(U; W^{2,2}_x)} \leq c(1 + \|u\|_{W^{2,2}_x}) \quad \forall u \in W^{2,2}(\mathbb{T}^2).
\]

In fact, all our results apply if we replace (2.1) and (2.2) by the corresponding norm estimates above.

Furthermore, the conditions imposed on \( \Phi \), particularly the first assumption from (2.1), allow us to define stochastic integrals. Given an \((\mathcal{F}_t)\)-progressively measurable process \( u \in L^2(\Omega; L^2(0, T; L^2(\mathbb{T}^2))) \), the stochastic integral
\[
t \mapsto \int_0^t \Phi(u) \, dW
\]
is a well defined process taking values in \( L^2(\mathbb{T}^2) \) (see [13] for the detailed construction). Moreover, we can multiply by test functions to obtain
\[
\left\langle \int_0^t \Phi(u) \, dW, \phi \right\rangle = \sum_{k \geq 1} \int_0^t \langle g_k(u), \phi \rangle \, d\beta_k, \quad \phi \in L^2(\mathbb{T}^2).
\]

Similarly, we can define stochastic integrals with values in \( W^{1,2}(\mathbb{T}^2) \) and \( W^{2,2}(\mathbb{T}^2) \) respectively if \( u \) belongs to the corresponding class.

The following lemma is a helpful tool to analyse the time-regularity of stochastic integrals (see, e.g., [6, Lemma 9.1.3. b)] or [19, Lemma 4.6]).
Lemma 1 Let \( \psi \in L^r(\Omega; L^r(0, T; L_2(\mathbb{R}^2))) \), \( r > 2 \), by an \((\mathcal{F}_t)\)-progressively measurable process and \( W \) a cylindrical \((\mathcal{F}_t)\)-Wiener process on \( \Omega \). Then the paths of the process \( Z_t := \int_0^t \psi \, dW \) are \( \mathbb{P} \)-a.s. Hölder continuous with exponent \( \alpha \in \left( \frac{1}{r}, \frac{1}{2} \right) \) and it holds

\[
\mathbb{E}\left[ \left\| Z \right\|^r_{C^\alpha([0,T]; L^2(\mathbb{R}^2))} \right] \leq c_\alpha \mathbb{E}\left[ \int_0^T \left\| \psi \right\|^2_{L_2(\Omega; L^2(\mathbb{R}^2))} \, dt \right]^{\frac{r}{2}}.
\]

2.2 The concept of solutions

In dimension two, pathwise uniqueness for weak solutions is known under (2.1), we refer the reader for instance to Capiński–Cutland [12] and Capiński [11]. Consequently, we may work with the definition of a weak pathwise solution.

Definition 1 Let \((\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})\) be a given stochastic basis with a complete right-continuous filtration and an \((\mathcal{F}_t)\)-cylindrical Wiener process \( W \). Let \( u_0 \) be an \( \mathcal{F}_0 \)-measurable random variable. Then \( u \) is called a **weak pathwise solution** to (1.1) with the initial condition \( u_0 \) provided

(a) the velocity field \( u \) is \((\mathcal{F}_t)\)-adapted and

\[
 u \in C([0, T]; L^2_{\text{div}}(\mathbb{R}^2)) \cap L^2(0, T; W^{1,2}_{\text{div}}(\mathbb{R}^2)) \quad \mathbb{P}\text{-a.s.},
\]

(b) the momentum equation

\[
 \int_{\mathbb{R}^2} u(t) \cdot \varphi \, dx - \int_{\mathbb{R}^2} u_0 \cdot \varphi \, dx = \int_0^t \int_{\mathbb{R}^2} \mu \nabla u : \nabla \varphi \, dx \, ds - \int_0^t \int_{\mathbb{R}^2} \Phi(u) : \nabla \varphi \, dx \, ds
\]

holds \( \mathbb{P} \)-a.s. for all \( \varphi \in C^\infty_c(\mathbb{R}^2) \) and all \( t \in [0, T] \).

Theorem 1 Let \( N = 2 \) and assume that \( \Phi \) satisfies (2.1). Let \((\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})\) be a given stochastic basis with a complete right-continuous filtration and an \((\mathcal{F}_t)\)-cylindrical Wiener process \( W \). Let \( u_0 \) be an \( \mathcal{F}_0 \)-measurable random variable such that \( u_0 \in L^r(\Omega; L^2_{\text{div}}(\mathbb{R}^2)) \) for some \( r > 2 \). Then there exists a unique weak pathwise solution to (1.1) in the sense of Definition 1 with the initial condition \( u_0 \).

Now, for \( \phi \in C^\infty_c(\mathbb{R}^2) \) we can insert \( \phi - \nabla \Delta^{-1} \text{div} \phi \) and obtain

\[
\int_{\mathbb{R}^2} u(t) \cdot \varphi \, dx + \int_0^t \int_{\mathbb{R}^2} \mu \nabla u : \nabla \varphi \, dx \, ds - \int_0^t \int_{\mathbb{R}^2} u : \nabla \varphi \, dx \, ds
\]

holds \( \mathbb{P} \)-a.s. for all \( \varphi \in C^\infty_c(\mathbb{R}^2) \) and all \( t \in [0, T] \).
\[ + \int_{T^2} \int_0^t \Phi(u) \, dW \cdot \varphi \, dx + \int_{T^2} \int_0^t \Phi^\pi \, dW \cdot \varphi \, dx, \quad (2.6) \]

where

\[ \pi_{\text{det}} = - \Delta^{-1} \text{div} \text{div}(u \otimes u), \]
\[ \Phi^\pi = - \nabla \Delta^{-1} \text{div} \Phi(u). \]

This corresponds to the stochastic pressure decomposition introduced in [5] (see also [6, Chap. 3] for a slightly different presentation). However, the situation with periodic boundary conditions we are considering here is much easier as the harmonic component of the pressure disappears.

### 2.3 Regularity of solutions

**Lemma 2** Let the assumptions of Theorem 1 be satisfied.

(a) We have

\[ \mathbb{E}\left[ \sup_{0 \leq t \leq T} \int_{T^2} |u|^2 \, dx + \int_Q |\nabla u|^2 \, dx \, dt \right]^{\frac{r}{2}} \leq c_r \mathbb{E}\left[ 1 + \|u_0\|_{L^2_x}^2 \right]^{\frac{r}{2}}. \quad (2.7) \]

(b) Assume that \( u_0 \in L^r(\Omega, W^{1,2}_{\text{div}}(T^2)) \) for some \( r \geq 2 \). Then we have

\[ \mathbb{E}\left[ \sup_{0 \leq t \leq T} \int_{T^2} |\nabla u|^2 \, dx + \int_Q |\nabla^2 u|^2 \, dx \, dt \right]^{\frac{r}{2}} \leq c_r \mathbb{E}\left[ 1 + \|u_0\|_{W^{1,2}_x}^2 \right]^{\frac{r}{2}}. \quad (2.8) \]

(c) Assume that \( u_0 \in L^r(\Omega, W^{2,2}_{\text{div}}(T^2)) \cap L^{5r}(\Omega, W^{1,2}_{\text{div}}(T^2)) \) for some \( r \geq 2 \) and that (2.2) holds. Then we have

\[ \mathbb{E}\left[ \sup_{0 \leq t \leq T} \int_{T^2} |\nabla^2 u|^2 \, dx + \int_Q |\nabla^3 u|^2 \, dx \, dt \right]^{\frac{r}{2}} \leq c_r \mathbb{E}\left[ 1 + \|u_0\|_{W^{2,2}_x}^2 + \|u_0\|_{W^{1,2}_x}^{10} \right]^{\frac{r}{2}}. \quad (2.9) \]

**Proof** Part (a) is the standard a priori estimate which follows from applying Itô’s formula to the functional \( f(u) = \frac{1}{2} \|u\|_{L^2_x}^2 \) (and using Burkholder–Davis–Gundy inequality, assumption (2.1) and Gronwall’s lemma). Note that this is legit in two dimensions since we have \( u \otimes u \in L^2(Q) \) \( \mathbb{P}\)-a.s. by Ladyshenskaya’s inequality.

The proof of (b) and (c) is quite similar to [20, Corollary 2.4.13]. However, we are working with a different setup. So, we decided to give a formal proof although it is certainly known to experts. The proof can be made rigorous by working with a Galerkin-type approximation and show that the following estimates are uniform with
Convergence rates for the numerical approximation... 559

respect to the dimension of the ansatz space. Such a procedure is quite standard, so we leave the details to the reader.

In order to show (b) we apply Itô’s formula to the function \( f_\gamma(u) := \frac{1}{2} \| \partial_\gamma u \|_{L^2}^2 \) (with \( \gamma \in \{1, 2\} \)) and obtain

\[
\frac{1}{2} \| \partial_\gamma u(t) \|_{L^2}^2 = \frac{1}{2} \| \partial_\gamma u_0 \|_{L^2}^2 + \int_0^t f'_\gamma(u) \, du + \frac{1}{2} \int_0^t f''_\gamma(u) \, d\langle \langle u \rangle \rangle \\
= \frac{1}{2} \| \partial_\gamma u_0 \|_{L^2}^2 + \int_{\mathbb{T}^2} \int_0^t \partial_\gamma u \cdot \partial_\gamma u \, dx \\
+ \frac{1}{2} \int_{\mathbb{T}^2} \int_0^t d\langle \langle \int_0^t \partial_\gamma (\Phi(u) \, dW) \rangle \rangle \, dx \\
=: (I) + (II) + (III).
\]

We take the supremum in time, the \( \xi \)th power and apply expectations. Summing over \( \gamma \), we find

\[
(II) = -(II)_1 - (II)_2 + (II)_3, \\
(II)_1 := \mu \int_0^t \int_{\mathbb{T}^2} |\nabla^2 u|^2 \, dx \, d\sigma, \\
(II)_2 := \int_{\mathbb{T}^2} \int_0^t \partial_\gamma u \cdot \partial_\gamma (\Phi(u) \, dW) \, dx, \\
(II)_3 := \int_0^t \int_{\mathbb{T}^2} (\nabla u) \cdot \Delta u \, dx \, d\sigma.
\]

In two dimensions we have \((II)_3 = 0\) by elementary calculations. So we are left with estimating \((II)_2\) and obtain

\[
(II)_2 = \sum_k \int_{\mathbb{T}^2} \int_0^t \partial_\gamma u \cdot \partial_\gamma (\Phi(u)e_k \, d\beta_k) \, dx \\
= \sum_k \int_{\mathbb{T}^2} \int_0^t \partial_\gamma u \cdot \partial_\gamma (g_k(\cdot, u) \, d\beta_k) \, dx \\
= \sum_k \int_{\mathbb{T}^2} \int_0^t \nabla_\xi g_k(\cdot, u) (\partial_\gamma u, \partial_\gamma u) \, d\beta_k \, dx \\
+ \sum_k \int_{\mathbb{T}^2} \int_0^t \partial_\gamma u \cdot \partial_\gamma g_k(\cdot, u) \, d\beta_k(\sigma) \, dx \\
=: (II)_2 + (II)_2.
\]
On account of assumption (2.1), Burkholder–Davis–Gundy inequality and Young’s inequality we obtain for arbitrary $\delta > 0$

$$
\mathbb{E}\left[ \sup_{0 \leq t \leq T} |(II)_{1/2}^{1/2} | \right] \leq \mathbb{E}\left[ \sup_{0 \leq t \leq T} \left| \int_{0}^{t} \sum_{k} \int_{T^2} \nabla \xi \mathbf{g}_k (\cdot, \mathbf{u}) (\partial_{\gamma} \mathbf{u}, \partial_{\gamma} \mathbf{u}) \, dx \, d\beta_k \right| \right]^{\frac{r}{2}}
$$

$$
\leq c \mathbb{E}\left[ \sum_{k} \int_{0}^{T} \left( \int_{T^2} \nabla \xi \mathbf{g}_k (\cdot, \mathbf{u}) (\partial_{\gamma} \mathbf{u}, \partial_{\gamma} \mathbf{u}) \, dx \right)^2 \, dr \right]^{\frac{r}{4}}
$$

$$
\leq c \mathbb{E}\left[ \left( \int_{0}^{T} \left( \int_{T^2} |\partial_{\gamma} \mathbf{u}|^2 \, dx \right)^2 \, dr \right)^{\frac{r}{4}}
$$

$$
\leq \delta \mathbb{E}\left[ \sup_{0 \leq t \leq T} \int_{T^2} |\nabla \mathbf{u}|^2 \, dx \right]^{\frac{r}{2}} + c(\delta) \mathbb{E}\left[ \int_{0}^{T} \int_{T^2} |\nabla \mathbf{u}|^2 \, dx \, dr \right]^{\frac{r}{2}}
$$

$$
\leq \delta \mathbb{E}\left[ \sup_{0 \leq t \leq T} \int_{T^2} |\nabla \mathbf{u}|^2 \, dx \right]^{\frac{r}{2}} + c(\delta) \mathbb{E}\left[ 1 + \| \mathbf{u}_0 \|_{L^2_x}^2 \right]^{\frac{r}{2}}
$$

using (2.7) in the last step. By similar arguments we gain

$$
\mathbb{E}\left[ \sup_{0 \leq t \leq T} |(II)_{1/2}^{1/2} | \right]^{\frac{r}{2}} \leq c \mathbb{E}\left[ \int_{0}^{T} \left( \int_{T^2} |\partial_{\gamma} \mathbf{g}_k (\cdot, \mathbf{u}) \cdot \partial_{\gamma} \mathbf{u} \, dx \right)^2 \, dr \right]^{\frac{r}{4}}
$$

$$
\leq c \mathbb{E}\left[ \left( \int_{0}^{T} \left( \int_{T^2} |\partial_{\gamma} \mathbf{u}| \, dx \right)^2 \, dr \right)^{\frac{r}{4}}
$$

$$
\leq c \mathbb{E}\left[ \sup_{(0,T)} \int_{T^2} |\mathbf{u}|^2 \, dx + \int_{0}^{T} \int_{T^2} |\nabla \mathbf{u}|^2 \, dx \, dr \right]^{\frac{r}{2}}
$$

$$
\leq c \mathbb{E}\left[ 1 + \| \mathbf{u}_0 \|_{L^2_x}^2 \right]^{\frac{r}{2}}.
$$

Finally, we have by (2.1)

$$(III) = \frac{1}{2} \int_{T^2} \int_{0}^{t} d\left( \int_{0}^{t} \partial_{\gamma} \left( \Phi (\mathbf{u}) \, dW \right) \right) \, dx
$$

$$
= \frac{1}{2} \sum_{k} \int_{T^2} \int_{0}^{t} d\left( \int_{0}^{t} \partial_{\gamma} \left( \Phi (\mathbf{u}) e_k \right) d\beta_k \right) \, dx
$$

$$
\leq \frac{1}{2} \sum_{k} \int_{0}^{t} \int_{T^2} |\nabla \xi \mathbf{g}_k (\cdot, \mathbf{u}) \partial_{\gamma} \mathbf{u}|^2 \, dx \, d\sigma
$$

$$
+ \frac{1}{2} \sum_{k} \int_{0}^{t} \int_{T^2} |\partial_{\gamma} \mathbf{g}_k (\cdot, \mathbf{u})|^2 \, dx \, d\sigma
$$

$$
\leq c \int_{0}^{t} \int_{T^2} |\nabla \mathbf{u}|^2 \, dx \, d\sigma + c \int_{0}^{t} \int_{T^2} |\mathbf{u}|^2 \, dx \, d\sigma.
$$
Hence we obtain by (2.7) that
\[
\mathbb{E}\left[ \sup_{0 \leq t \leq T} |(III)| \right]^{\frac{5}{2}} \leq c \mathbb{E}\left[ 1 + \|u_0\|_{L^2_x}^2 \right]^{\frac{5}{2}}.
\]

Plugging all together and choosing \(\delta\) small enough we have shown (2.8).

The proof of (c) is similar: we simply differentiate once more. We apply Itô’s formula to the function \(f^\beta(u) := \frac{1}{2} \|\partial^\beta u\|_{L^2_x}^2\) where \(\beta \in \mathbb{N}_0^2\) is a multi-index of length 2. We obtain
\[
\frac{1}{2} \|\partial^\beta u(t)\|_{L^2_x}^2 = \frac{1}{2} \|\partial^\beta u_0\|_{L^2_x}^2 + \int_0^t \int_{T_2} \partial^\beta u \cdot \partial^\beta u \, dx
\]
\[
+ \frac{1}{2} \int_0^t \int_{T_2} \partial^\beta (\Phi(u) \, dW) \, dx =: (I) + (II) + (III),
\]
where
\[
(II) = -(II)_1 + (II)_2 - (II)_3,
\]
\[
(II)_1 := \mu \int_0^t \int_{T_2} |\partial^\beta \nabla u|^2 \, dx \, d\sigma,
\]
\[
(II)_2 := \int_0^t \int_{T_2} \partial^\beta u \cdot \partial^\beta (\Phi(u) \, dW) \, dx,
\]
\[
(II)_3 := \int_0^t \int_{T_2} \partial^\beta (\nabla u) \cdot \partial^\beta u \, dx \, d\sigma.
\]

The main difference is that \((II)_3\) does not vanish. By [20, Lemma 2.1.20] (with \(m = 2\)) and Young’s inequality we have
\[
\left| \int_{T_2} \partial^\beta \text{div}(u \otimes u) \cdot \partial^\beta u \, dx \right| \leq c \|u\|_{W^{3,2}}^2 \|u\|_{W^{4,2}}^3 \|u\|_{L^2_x}^2
\]
\[
\leq \delta \|u\|_{W^{3,2}}^2 + c(\delta) \|u\|_{W^{4,2}}^6 \|u\|_{L^2_x}^4
\]
\[
\leq \delta \|u\|_{W^{3,2}}^2 + c(\delta) (\|u\|_{W^{1,2}}^{10} + \|u\|_{L^2_x}^{10}),
\]
where \(\delta > 0\) is arbitrary. This implies
\[
\mathbb{E}\left[ \sup_{0 \leq t \leq T} |(II)_3| \right]^{\frac{5}{2}} \leq \delta \mathbb{E}\left[ \int_0^T \|u\|_{W^{3,2}}^2 \, dt \right]^{\frac{5}{2}} + c(\delta) \mathbb{E}\left[ \sup_{0 \leq t \leq T} \|u\|_{W^{4,2}}^6 + \sup_{0 \leq t \leq T} \|u\|_{L^2_x}^4 \right]^{\frac{10}{2}}
\]
\[
\leq \delta \mathbb{E}\left[ \int_0^T \|u\|_{W^{3,2}}^2 \, dt \right]^{\frac{5}{2}} + c(\delta) \mathbb{E}\left[ \|u_0\|_{W^{1,2}}^{10} \right]^{\frac{5}{2}}
\]
due to (2.8). By arguments similar to the proof of (b), using (2.2), we gain
\[
\mathbb{E}\left[ \sup_{0 \leq t \leq T} |(II)_2| \right]^{\frac{5}{2}}
\]
\[ \delta \mathbb{E} \left[ \sup_{0 \leq t \leq T} \| u \|^2_{W^{1,2}_2} \right]^{\frac{r}{2}} + c(\delta) \mathbb{E} \left[ \sup_{0 \leq t \leq T} \| u \|^2_{L^2} + \sup_{0 \leq t \leq T} \| u \|^2_{W^{1,2}_2} + \int_{0}^{T} \| u \|^2_{W^{1,2}_2} \, dt \right]^{\frac{r}{2}} \leq \delta \mathbb{E} \left[ \sup_{0 \leq t \leq T} \| u \|^2_{W^{1,2}_2} \right]^{\frac{r}{2}} + c \mathbb{E} \left[ 1 + \| u_0 \|^2_{W^{1,2}_2} \right]^{\frac{r}{2}} \]

using again (2.8). Finally, we get (2.7) that

\[ \mathbb{E} \left[ \sup_{0 \leq t \leq T} \left| (III) \right| \right]^{\frac{r}{2}} \leq c \mathbb{E} \left[ 1 + \| u_0 \|^2_{W^{1,2}_2} \right]^{\frac{r}{2}} \]

arguing again similarly to (b) and using (2.2). Again the claim follows by choosing \( \delta \) small enough.

Under the assumptions of Lemma 2 (b) equation (1.1) is satisfied strongly in the analytical sense. That is we have

\[ u(t) = u(0) + \int_{0}^{t} \left[ \mu \Delta u - (\nabla u) u - \nabla \pi_{\text{det}} \right] \, d\sigma + \int_{0}^{t} \left[ \Phi(u) + \Phi^\pi \right] \, dW \quad (2.11) \]

\( \mathbb{P} \)-a.s. for all \( t \in [0, T] \), recall equation (3.5). In the following we analyze the regularity of the pressure components \( \pi_{\text{det}} \) and \( \Phi^\pi \). In the following the subscript \( w^* \) denotes Bochner-measurability with respect to the weak*-topology.

**Corollary 1**

(a) Under the assumptions of Lemma 2 we have

\[ \pi_{\text{det}} \in L^\frac{r}{2} (\Omega, L^2(0, T; L^2(\mathbb{T}^2))), \]
\[ \Phi^\pi \in L^r (\Omega; L^\infty_w(0, T; L^2(\mathbb{U}; L^2(\mathbb{T}^2)))). \]

(b) Under the assumptions of Lemma 2(b) we have

\[ \pi_{\text{det}} \in L^\frac{r}{2} (\Omega, L^2(0, T; W^{1,2}(\mathbb{T}^2))), \]
\[ \Phi^\pi \in L^r (\Omega; L^\infty_w(0, T; L^2(\mathbb{U}; W^{1,2}(\mathbb{T}^2)))). \]

(c) Under the assumptions of Lemma 2 (c) we have

\[ \pi_{\text{det}} \in L^\frac{r}{2} (\Omega, L^2(0, T; W^{2,2}(\mathbb{T}^2))), \]
\[ \Phi^\pi \in L^r (\Omega; L^\infty_w(0, T; L^2(\mathbb{U}; W^{2,2}(\mathbb{T}^2)))). \]

**Proof** The key tool is the continuity of \( \Delta^{-1} \) (from \( W^{k-2,p}(\mathbb{T}^2) \to W^k,p(\mathbb{T}^2) \) for all \( k \in \mathbb{N}_0 \) and \( 1 < p < \infty \)). So, the regularity transfers from \( u \otimes u \) to \( \pi_{\text{det}} \). We obtain by Ladyshenskaya’s inequality

\[ \int_{0}^{T} \int_{\mathbb{T}^2} |\pi_{\text{det}}|^2 \, dx \, dt = \int_{0}^{T} \int_{\mathbb{T}^2} |\Delta^{-1} \text{div} (u \otimes u)|^2 \, dx \, dt \leq c \int_{0}^{T} \int_{\mathbb{T}^2} |u|^4 \, dx \, dt \]
\[ \leq c \| u \|_{L_t^\infty L_x^2}^2 \| \nabla u \|_{L_t^2 L_x^2}^2 \leq c \left( \| u \|_{L_t^\infty L_x^2}^4 + \| \nabla u \|_{L_t^2 L_x^2}^4 \right) \]

such that

\[ \mathbb{E} \left[ \int_0^T \int_{\Omega^2} |\pi_{\text{det}}|^2 \, dx \, dt \right] \leq c \mathbb{E} \left[ \| u \|_{L_t^\infty L_x^2}^2 + \| \nabla u \|_{L_t^2 L_x^2}^2 \right]^\frac{\gamma}{2} < \infty \]

using Lemma 2 (a). The estimates for (b) and (c) are very similar. We have to compare \( \nabla \pi \) with \( |u| |\nabla u| \), where we have

\[ |u| |\nabla u| \leq |u|^2 + |\nabla u|^2 \in L^\frac{\gamma}{2} (\Omega; L^2 (Q)) \]

under the assumptions of Lemma 2 (b). Similarly, \( \nabla^2 \pi \) behaves as \( |u| |\nabla^2 u| + |\nabla u|^2 \) which belongs to the same class since Lemma 2 (c) applies.

Now, we investigate the regularity of \( \Phi^\pi \). We use continuity \( \Delta^{-1} \) to obtain

\[ \mathbb{E} \left[ \sup_{0 \leq t \leq T} \| \Phi^\pi \|_{L_2(\mathcal{U}; L_x^2)}^2 \right] \leq \mathbb{E} \left[ \sup_{0 \leq t \leq T} \| \nabla \Delta^{-1} \text{div} \Phi (u) \|_{L_2(\mathcal{U}; L_x^2)}^2 \right] \]

\[ = \mathbb{E} \left[ \sup_{0 \leq t \leq T} \sum_{k \geq 1} \| \nabla \Delta^{-1} \text{div} g_k (\cdot, u) \|_{L_x^2}^2 \right] \]

\[ \leq c \mathbb{E} \left[ \sup_{0 \leq t \leq T} \sum_{k \geq 1} \| g_k (\cdot, u) \|_{L_x^2}^2 \right] \]

\[ \leq c \mathbb{E} \left[ 1 + \sup_{0 \leq t \leq T} \| u \|_{W_2^1}^2 \right] < \infty \]

using (2.1) and Lemma 2 (a). Similarly, we have

\[ \mathbb{E} \left[ \sup_{0 \leq t \leq T} \| \Phi^\pi \|_{L_2(\mathcal{U}; W_{1,2}^1)}^2 \right] \leq c \mathbb{E} \left[ \sup_{0 \leq t \leq T} \sum_{k \geq 1} \| g_k (\cdot, u) \|_{W_{1,2}^1}^2 \right] \]

\[ \leq c \mathbb{E} \left[ 1 + \sup_{0 \leq t \leq T} \| u \|_{W_{1,2}^1}^2 \right] < \infty \]

using (2.1) and Lemma 2 (b), as well as

\[ \mathbb{E} \left[ \sup_{0 \leq t \leq T} \| \Phi^\pi \|_{L_2(\mathcal{U}; W_{2,2}^2)}^2 \right] \leq c \mathbb{E} \left[ \sup_{0 \leq t \leq T} \sum_{k \geq 1} \| g_k (\cdot, u) \|_{W_{2,2}^2}^2 \, dt \right] \]

\[ \leq c \mathbb{E} \left[ 1 + \sup_{0 \leq t \leq T} \| u \|_{W_{2,2}^2}^2 \right] < \infty \]

by (2.2) and the Lemma 2 (c).
Finally, we investigate the time-regularity of the velocity field.

**Corollary 2** (a) Let the assumptions of Lemma 2 (b) be satisfied for some \( r > 2 \). Then we have

\[
\mathbb{E}\left[ \| u \|_{C^\alpha([0,T];L^2_x)} \right] < \infty
\]

(2.12)

for all \( \alpha < \frac{1}{2} \).

(b) Let the assumptions of Lemma 2 (c) be satisfied for some \( r > 2 \). Then we have

\[
\mathbb{E}\left[ \| u \|_{C^\alpha([0,T];W^{1,2}_x)} \right] < \infty
\]

(2.13)

for all \( \alpha < \frac{1}{2} \).

**Proof** We start with (a) and analyse each term in equation (2.11) separately. Lemma 2 (b) implies

\[
\int_0^t \Delta u \, d\sigma \in L^r(\Omega; W^{1,2}(0,T; L^2(\mathbb{T}^2))).
\]

As seen in the proof of Corollary 1, \( \pi_{\text{det}} \) and \( u \otimes u \) have the same regularity. In particular, Corollary 1 (b) yields

\[
\int_0^t \left( \text{div}(u \otimes u) + \nabla \pi_{\text{det}} \right) \, d\sigma \in L^\infty(\Omega; W^{1,2}(0,T; L^2(\mathbb{T}^2))).
\]

Finally, we have

\[
\int_0^t \Phi(u) \, dW \in L^r(\Omega; C^\alpha([0,T]; L^2(\mathbb{T}^2))).
\]

by combing Lemma 1 with (2.3). The same conclusion holds for \( \Phi^\pi \) using Lemma 1 (a). Plugging all together and noting the embedding \( W^{1,2}(0,T; X) \hookrightarrow C^\alpha([0,T]; X) \) for any separably Banach space \( X \) the claim follows.

The proof of (b) follows along the same lines using the higher regularity from Lemma 2 (c), Corollary 1 (c) and (2.4). |}

**2.4 Discretization in space**

We work with a standard finite element set-up for incompressible fluid mechanics, see e.g. [7,15]. We denote by \( T_h \) a quasi-uniform subdivision of \( \mathbb{T}^2 \) into triangles of maximal diameter \( h > 0 \). For \( S \subset \mathbb{R}^2 \) and \( \ell \in \mathbb{N}_0 \) we denote by \( \mathcal{P}_\ell(S) \) the polynomials on \( S \) of degree less than or equal to \( \ell \). Moreover, we set \( \mathcal{P}_{-1}(S) := \{0\} \).

Let us characterize the finite element spaces \( V_h(\mathbb{T}^2) \) and \( P_h(\mathbb{T}^2) \) as

\[
V_h(\mathbb{T}^2) := \{ v_h \in W^{1,2}(\mathbb{T}^2) : v_h|_S \in \mathcal{P}_\ell(S) \forall S \in T_h \},
\]

\[
P_h(\mathbb{T}^2) := \{ p_h \in L^2(\mathbb{T}^2) : p_h|_S \in \mathcal{P}_\ell(S) \forall S \in T_h \}.
\]
Convergence rates for the numerical approximation... 565

$P^h(\mathbb{T}^2) := \{\pi_h \in L^2(\mathbb{T}^2) : \pi_h|_S \in P_j(S) \ \forall S \in \mathcal{T}_h\}.$

We will assume that $i$ and $j$ are both natural to get (2.15) below (this is different from [9], where also $j = 0$ is allowed). In order to guarantee stability of our approximations we relate $V^h(\mathbb{T}^2)$ and $P^h(\mathbb{T}^2)$ by the inf-sup condition, that is we assume that

$$\sup_{v_h \in V^h(\mathbb{T}^2), v_h \neq 0} \frac{\int_{\mathbb{T}^2} \text{div} v_h \pi_h \, dx}{\|\nabla v_h\|_{L^2}} \geq C \|\pi_h\|_{L^2} \ \forall \pi_h \in P^h(\mathbb{T}^2),$$

where $C > 0$ does not depend on $h$. This gives a relation between $i$ and $j$ (for instance the choice $(i, j) = (1, 0)$ is excluded whereas $(i, j) = (2, 0)$ is allowed). Finally, we define the space of discretely solenoidal finite element functions by

$$V^h_{\text{div}}(\mathbb{T}^2) := \left\{v_h \in V^h(\mathbb{T}^2) : \int_{\mathbb{T}^2} \text{div} v_h \pi_h \, dx = 0 \ \forall \pi_h \in P^h(\mathbb{T}^2) \right\}.$$  

Let $\Pi_h : L^2(\mathbb{T}^2) \rightarrow V^h_{\text{div}}(\mathbb{T}^2)$ be the $L^2(\mathbb{T}^2)$-orthogonal projection onto $V^h_{\text{div}}(\mathbb{T}^2)$. The following results concerning the approximability of $\Pi_h$ are well-known (see, for instance [18]). There is $c > 0$ independent of $h$ such that we have

$$\int_{\mathbb{T}^2} \left| \frac{v - \Pi_h v}{h} \right|^2 \, dx + \int_{\mathbb{T}^2} |\nabla v - \nabla \Pi_h v|^2 \, dx \leq c \int_{\mathbb{T}^2} |\nabla v|^2 \, dx \quad (2.14)$$

for all $v \in W^{1,2}_{\text{div}}(\mathbb{T}^2)$ and

$$\int_{\mathbb{T}^2} \left| \frac{v - \Pi_h v}{h} \right|^2 \, dx + \int_{\mathbb{T}^2} |\nabla v - \nabla \Pi_h v|^2 \, dx \leq c h^2 \int_{\mathbb{T}^2} |\nabla^2 v|^2 \, dx \quad (2.15)$$

for all $v \in W^{2,2}_{\text{div}}(\mathbb{T}^2)$. Similarly, if $\Pi^\pi_h : L^2(\mathbb{T}^2) \rightarrow P^h(\mathbb{T}^2)$ denotes the $L^2(\mathbb{T}^2)$-orthogonal projection onto $P^h(\mathbb{T}^2)$, we have

$$\int_{\mathbb{T}^2} \left| \frac{p - \Pi^\pi_h p}{h} \right|^2 \, dx \leq c \int_{\mathbb{T}^2} |\nabla p|^2 \, dx \quad (2.16)$$

for all $p \in W^{1,2}(\mathbb{T}^2)$ and

$$\int_{\mathbb{T}^2} \left| \frac{p - \Pi^\pi_h p}{h} \right|^2 \, dx \leq c h^2 \int_{\mathbb{T}^2} |\nabla^2 p|^2 \, dx \quad (2.17)$$

for all $p \in W^{2,2}(\mathbb{T}^2)$. Note that (2.17) requires the assumption $j \geq 1$ in the definition of $P^h(\mathbb{T}^2)$, whereas (2.16) also holds for $j = 0$.  

Springer
3 Time-discretization

We consider an equidistant partition of $[0, T]$ with mesh size $\Delta t = T/M$ and set $t_m = m \Delta t$. Let $u_0$ be an $\mathcal{F}_0$-measurable random variable with values in $W^{1,2}_{\text{div}}(\mathbb{T}^2)$. We aim at constructing iteratively a sequence of $\mathcal{F}_t$-measurable random variables $u_m$ with values in $W^{1,2}_{\text{div}}(\mathbb{T}^2)$ such that for every $\phi \in W^{1,2}_{\text{div}}(\mathbb{T}^2)$ it holds true $\mathbb{P}$-a.s.

\[
\int_{T^2} u_m \cdot \phi \, dx + \Delta t \left( \int_{T^2} (\nabla u_m) u_m : \phi \, dx + \mu \int_{T^2} \nabla u_m : \nabla \phi \, dx \right) = \int_{T^2} u_{m-1} \cdot \phi \, dx + \int_{T^2} \Phi(u_{m-1}) \Delta_m W \cdot \phi \, dx,
\]

where $\Delta_m W = W(t_m) - W(t_{m-1})$. The existence of a unique $u_m$ (given $u_{m-1}$ and $\Delta_m W$) solving (3.1) is straightforward as it is a stationary Navier–Stokes system. The following result follows from Lemma 3.1 in [9].

**Lemma 3** Assume that $u_0 \in L^{2q}(\Omega; W^{1,2}_{\text{div}}(\mathbb{T}^2))$ for some $1 \leq q < \infty$. Suppose that $\Phi$ satisfies (2.1). Then the iterates $(u_m)_{m=1}^M$ given by (3.1) are $\mathcal{F}_t$-measurable. Moreover, the following estimates hold uniformly in $M$:

\[
\mathbb{E} \left[ \max_{1 \leq m \leq M} \|u_m\|_{W^{1,2}}^{2q} + \Delta t \sum_{k=1}^M \|u_m\|_{W^{1,2}}^{2q-2} \|\nabla^2 u_m\|_{L^2}^2 \right] \leq c(q, T, u_0),
\]

\[
\mathbb{E} \left[ \sum_{k=1}^M \|u_m - u_{m-1}\|_{W^{1,2}}^2 \|\nabla u_m\|_{L^2}^2 \right] \leq c(T, u_0),
\]

\[
\mathbb{E} \left[ \left( \sum_{k=1}^M \|u_m - u_{m-1}\|_{W^{1,2}}^2 \right)^4 + \left( \Delta t \sum_{k=1}^M \|\nabla^2 u_m\|_{L^2}^2 \right)^4 \right] \leq c(T, u_0).
\]

Now, for $\phi \in W^{1,2}(\mathbb{T}^2)$ we can insert $\phi - \nabla \Delta^{-1} \text{div} \Phi \in W^{1,2}_{\text{div}}(\mathbb{T}^2)$ in (3.1) and obtain

\[
\int_{T^2} u_m \cdot \phi \, dx + \Delta t \left( \int_{T^2} (\nabla u_m) u_m : \phi \, dx + \mu \int_{T^2} \nabla u_m : \nabla \phi \, dx \right) = \int_{T^2} u_{m-1} \cdot \phi \, dx + \Delta t \int_{T^2} \pi_m^{\text{det}} \text{div} \Phi \, dx
\]

\[
+ \int_{T^2} \Phi(u_{m-1}) \Delta_m W \cdot \phi \, dx + \int_{T^2} \int_0^t \Phi_{m-1}^{\pi} \Delta_m W \cdot \phi \, dx,
\]

where

\[
\pi_m^{\text{det}} = -\Delta^{-1} \text{div} (u_m \otimes u_m),
\]

\[
\Phi_{m-1}^{\pi} = -\nabla \Delta^{-1} \text{div} \Phi(u_{m-1}).
\]
**Lemma 4** Assume that \( u_0 \in L^8(\Omega, W^{1.2}_{div}(\mathbb{T}^2)) \) and that \( \Phi \) satisfies (2.1). For all \( m \in \{1, \ldots, M\} \) the random variable \( \pi_m^{\text{det}} \) is \( \mathcal{F}_{t_m} \)-measurable, has values in \( W^{1.2}(\mathbb{T}^2) \) and we have

\[
\mathbb{E} \left[ \Delta t \sum_{m=1}^{M} \left\| \nabla \pi_m^{\text{det}} \right\|_{L^2_x}^2 \right] \leq C
\]

uniformly in \( \Delta t \).

**Remark 1** A corresponding result is shown in [9, Lemma 3.2] for the full pressure provided the noise is divergence-free (in this case \( \Phi_{\pi} \) vanishes). This is quite restrictive as it means that \( \Phi \) is linear in \( u \).

**Proof** The \( \mathcal{F}_{t_m} \)-measurability of \( \pi_m^{\text{det}} \) follows directly from the one of \( u_m \) stated in Lemma 3. By continuity of the operator \( \nabla \Delta^{-1} \text{div} \) on \( L^2(\mathbb{T}^2) \) we have

\[
\left\| \nabla \pi_m^{\text{det}} \right\|_{L^2_x}^2 \leq c \left\| \text{div}(u_m \otimes u_m) \right\|_{L^2_x}^2 \leq c \left\| u_m \right\|_{L^4_x}^2 \left\| \nabla u_m \right\|_{L^4_x}^2
\]

\[
\leq c \left\| u_m \right\|_{L^2_x} \left\| \nabla u_m \right\|_{L^2_x} \left\| \nabla^2 u_m \right\|_{L^2_x} \leq c \left\| u_m \right\|_{L^2_x}^2 + c \left\| \nabla u_m \right\|_{L^4_x}^2 \left\| \nabla^2 u_m \right\|_{L^2_x}^2
\]

\( \mathbb{P} \)-a.s. using also Ladyshenskaya’s inequality \( \| v \|_{L^4_x}^2 \leq c \| v \|_{L^2_x} \| \nabla v \|_{L^2_x} \) which holds in two-dimensions. Now, summing with respect to \( m \), applying expectations and using Lemma 3 yields the claim. \( \square \)

**Lemma 5** Assume that \( u_0 \in L^{8}(\Omega, W^{1.2}_{div}(\mathbb{T}^2)) \) and that \( \Phi \) satisfies (2.1). For all \( m \in \{1, \ldots, M\} \) the random variable \( \Phi_{\pi} \) is \( \mathcal{F}_{t_m} \)-measurable, has values in \( L^2(\mathcal{U}; W^{1.2}(\mathbb{T}^2)) \) and we have

\[
\mathbb{E} \left[ \Delta t \sum_{m=1}^{M} \left\| \Phi_{\pi} \right\|_{L^2(\mathcal{U}; W^{1.2})}^2 \right] \leq C
\]

uniformly in \( \Delta t \).

**Proof** As for Lemma 4 the proof mainly relies on the continuity of \( \nabla \Delta^{-1} \text{div} \) on \( L^2(\mathbb{T}^2) \). Here, we have by (2.4)

\[
\left\| \Phi_{\pi} \right\|_{L^2(\mathcal{U}; W^{1.2})}^2 = \sum_{k \geq 1} \left\| \nabla \Delta^{-1} \text{div}(\Phi(u_m)e_k) \right\|_{W^{1.2}_x}^2
\]

\[
\leq c \sum_{k \geq 1} \left\| \Phi(u_m)e_k \right\|_{W^{1.2}_x}^2 = c \left\| \Phi(u_m) \right\|_{L^2(\mathcal{U}; W^{1.2})}^2 \leq c \left( 1 + \left\| \nabla u_m \right\|_{W^{1.2}_x}^2 \right).
\]

Summing over \( m \), applying expectations and using Lemma 3 finishes the proof. \( \square \)

Following [9] we set for \( \varepsilon > 0 \)

\[
\Omega_{\Delta t}^\varepsilon = \left\{ \omega \in \Omega \left| \max_{1 \leq m \leq M} \left\| \nabla u_m \right\|_{L^2_x}^2 \leq -\varepsilon \log(\Delta t) \right. \right\}
\]

(3.6)
such that
\[
P(\Omega^\delta_{\Delta t}) \geq 1 - \frac{\mathbb{E}\left[ \max_{1 \leq m \leq M} \| \nabla u_m \|_{L^2_x}^2 \right]}{-\varepsilon \log(\Delta t)} \geq 1 + \frac{C}{\varepsilon \log \Delta t}
\]

using Lemma 3. We obtain the following result.

**Theorem 2** Assume that (2.1) holds and that \( u_0 \in L^8(\Omega, W^{1,2}_{div}(\mathbb{T}^2)) \) is an \( \xi_0 \)-measurable random variable. Let \( u \) be the unique strong solution to (1.1) in the sense of Definition 1. Assume that we have
\[
\mathbb{E}\left[ \| u \|_{C^\alpha([0, T]; L^4_x)}^4 \right] < \infty, \quad \mathbb{E}\left[ \| u \|_{C^\alpha([0, T]; W^{1,2}_x)}^2 \right] < \infty,
\]
for some \( \alpha \in (0, \frac{1}{2}) \); recall Corollary 2. Let \((u_m)_{m=1}^M\) be the solution to (3.1). Then we have the error estimate
\[
\mathbb{E}\left[ \mathbf{1}_{\Omega^\delta_{\Delta t}} \left( \max_{1 \leq m \leq M} \| u(t_m) - u_m \|_{L^2_x}^2 + \Delta t \sum_{m=1}^M \| \nabla u(t_m) - \nabla u_m \|_{L^2_x}^2 \right) \right] \leq c_\varepsilon (\Delta t)^{2\alpha - \varepsilon}
\]
for any \( \varepsilon > 0 \).

**Remark 2**
- Estimate (4.3) improves the result from [9, Thm. 3.1], where the convergence rate is only \( \alpha - \varepsilon \).
- In the paper [4] the time-discretization of the stochastic Navier–Stokes equations is analysed. The corresponding error does not contain an indicator function such as \( \mathbf{1}_{\Omega^\delta_{\Delta t}} \). The convergence rate is, however, only of logarithmic order.

**Proof** Subtracting (1.1) and (3.1) we obtain the equation for the error \( e_m = u(t_m) - u_m \) which reads as
\[
\int_{T^2} e_m \cdot \phi \, dx + \int_{t_{m-1}}^{t_m} \left( \int_{T^2} \left( (\nabla u)(t) - (\nabla u_m)(t) \right) u_m \cdot \phi \, dx + \mu \int_{T^2} \nabla e_m : \nabla \phi \, dx \right) \, dt = \int_{T^2} e_{m-1} \cdot \phi \, dx + \mu \int_{t_{m-1}}^{t_m} \left( \int_{T^2} (\nabla u(t) - \nabla u_m) : \nabla \phi \right) \, dx \, dt + \int_{T^2} \left( \int_{t_{m-1}}^{t_m} \Phi(u) \, dW - \Phi(u_m - 1) M \Delta W \right) \cdot \phi \, dx
\]
for all \( \phi \in W^{1,2}_{div}(\mathbb{T}^2) \). Choosing \( \phi = e_m \) implies
\[
\frac{1}{2} \int_{T^2} |e_m|^2 \, dx + \frac{1}{2} \int_{T^2} |e_m - e_{m-1}|^2 \, dx + \mu \Delta t \int_{T^2} |\nabla e_m|^2 \, dx = \frac{1}{2} \int_{T^2} |e_{m-1}|^2 \, dx - \mu \int_{t_{m-1}}^{t_m} \left( \nabla u(t_m) - \nabla u(t) \right) : \nabla e_m \, dx \, dt
\]
\[
\begin{align*}
&+ \int_{t_m}^{t_{m-1}} \int_{\mathbb{T}^2} ((\nabla u) - (\nabla u_m) u_m) \cdot e_m \, dx \, dt \\
&+ \int_{\mathbb{T}^2} \left( \int_{t_{m-1}}^{t_m} \Phi(u) \, dW - \Phi(u_{m-1}) \Delta_m W \right) \cdot e_m \, dx.
\end{align*}
\]

Iterating this equality and following the arguments in [9, proof of Thm. 3.1] yields

\[
\begin{align*}
\mathbb{E} \left[ \mathbf{1}_{\Omega_{\Delta t}} \left( \max_{1 \leq m \leq M} \| u(t_m) - u_m \|^2_{L^2} + \Delta t \sum_{m=1}^{M} \| \nabla u(t_m) - \nabla u_m \|^2_{L^2} \right) \right] \\
\leq c (\Delta t)^{2\alpha - \varepsilon} + c \mathbb{E} \left[ \sum_{m=1}^{M} \int_{t_{m-1}}^{t_m} \int_{\mathbb{T}^2} |\nabla u(t_m) - \nabla u(t)|^2 \, dx \, dt \right].
\end{align*}
\]

(3.10)

Note that only the first bound from (3.7) has been used for (3.10). The second bound from (3.7), not used in [9], allows us to estimate the remaining integral by

\[
\begin{align*}
\mathbb{E} \left[ \sum_{m=1}^{M} \int_{t_{m-1}}^{t_m} \int_{\mathbb{T}^2} |\nabla u(t_m) - \nabla u(t)|^2 \, dx \, dt \right] \leq c (\Delta t)^{2\alpha}
\end{align*}
\]

which finishes the proof. \[ \square \]

4 Finite element based space-time approximation

Now we consider a fully practical scheme combining the implicite Euler scheme in time (as in the last section) with a finite element approximation in space. For a given \( h > 0 \) let \( u_{h,0} \) be an \( \mathcal{F}_0 \)-measurable random variable with values in \( V^h_{\text{div}}(\mathbb{T}^2) \) (for instance \( \Pi_h u_0 \)). We aim at constructing iteratively a sequence of random variables \( u_{h,m} \) with values in \( V^h_{\text{div}}(\mathbb{T}^2) \) such that for every \( \phi \in V^h_{\text{div}}(\mathbb{T}^2) \) it holds true \( \mathbb{P}\text{-a.s.} \)

\[
\begin{align*}
&\int_{\mathbb{T}^2} u_{h,m} \cdot \phi \, dx + \Delta t \int_{\mathbb{T}^2} ((\nabla u_{h,m}) u_{h,m-1} + (\text{div} u_{h,m-1}) u_{h,m}) \cdot \phi \, dx \\
&+ \mu \Delta t \int_{\mathbb{T}^2} \nabla u_{h,m} : \nabla \phi \, dx = \int_{\mathbb{T}^2} u_{h,m-1} \cdot \phi \, dx + \int_{\mathbb{T}^2} \Phi(u_{h,m-1}) \Delta_m W \cdot \phi \, dx,
\end{align*}
\]

(4.1)

where \( \Delta_m W = W(t_m) - W(t_{m-1}) \). We quote the following result concerning the existence of solutions \( u_{h,m} \) to (4.1) from [8, Lemma 3.1].

Lemma 6 Let \( 1 \leq q < \infty \). Assume that \( u_{h,0} \in L^2(\Omega; V^h_{\text{div}}(\mathbb{T}^2)) \) is an \( \mathcal{F}_0 \)-measurable random variable and that \( \mathbb{E} [ \| u_{h,0} \|^2_{L^2} ] \leq K \) uniformly in \( h \) for some \( K > 0 \). Suppose that \( \Phi \) satisfies (2.1). Then the iterates \( (u_{h,m})_{m=1}^{M} \) given by (4.1) are \( \mathcal{F}_m \)-measurable.
Moreover, the following estimate holds uniformly in $M$ and $h$:

$$
E \left[ \max_{1 \leq m \leq M} \| u_{h,m} \|_{L^2}^{2q} + \Delta t \sum_{k=1}^{M} \| u_{h,m} \|_{L^2}^{2q-2} \| \nabla u_{h,m} \|_{L^2}^2 \right] \leq c(q, T, K). \quad (4.2)
$$

### 4.1 Error analysis

In this subsection we establish convergence with rates of the above defined algorithm. We introduce for $\varepsilon > 0$ the sample set

$$
\Omega^\varepsilon_h = \left\{ \omega \in \Omega \left| \max_{0 \leq m \leq M} \left( \| \nabla u_m \|_{L^2}^4 + \| u_{h,m} \|_{L^2}^2 \right) \leq -\varepsilon \log h \right. \right\}
$$

which can be controlled by

$$
P(\Omega^\varepsilon_h) \geq 1 - \frac{E \left[ \max_{1 \leq m \leq M} \left( \| \nabla u_m \|_{L^2}^4 + \| u_{h,m} \|_{L^2}^2 \right) \right]}{-\varepsilon \log h} \geq 1 + \frac{C}{\varepsilon \log h}
$$

using Lemma 3 and 6. We also recall the definition of $\Omega^\varepsilon_{\Delta t}$ in (3.6). We are now ready to state our main result.

**Theorem 3** Let $u_0 \in L^2(\Omega, W_{\text{div}}^{1,2}(\mathbb{T}^2)) \cap L^8(\Omega; L^2_{\text{div}}(\mathbb{T}^2))$ be $\mathcal{F}_0$-measurable and assume that $\Phi$ satisfies (2.1). Let $u$ be the unique strong solution to (1.1) in the sense of Definition 1. Suppose further that

$$
E \left[ \| u \|_{C^\alpha([0,T]; L^2)}^4 \right] < \infty, \quad E \left[ \| u \|_{C^\alpha([0,T]; W^{1,2})}^2 \right] < \infty,
$$

for $\alpha \in (0, \frac{1}{2})$; recall Corollary 2. Assume that $L \Delta t \leq (\varepsilon \log h)^{-1}$ for some $L > 0$.

Then we have

$$
E \left[ \mathbf{1}_{\Omega^\varepsilon_{\Delta t} \cap \Omega^\varepsilon_h} \left( \max_{1 \leq m \leq M} \| u(t_m) - u_{h,m} \|_{L^2}^2 + \sum_{m=1}^{M} \Delta t \| \nabla u(t_m) - \nabla u_{h,m} \|_{L^2}^2 \right) \right] \leq c \left( h^2 + (\Delta t)^{2\alpha - \varepsilon} \right), \quad (4.3)
$$

where $(u_{h,m})_{m=1}^M$ is the solution to (4.1) with $u_{h,0} = \Pi_h u_0$. The constant $c$ in (4.3) is independent of $M$ and $h$.

**Remark 3** We do not expect that it is possible to avoid an indicator function in general (see [24] for the numerical approximation of stochastic PDEs with non-Lipschitz nonlinearities). But it is not clear if our choice of the sample subset is optimal.

The rest of the paper is devoted to the proof of Theorem 3. In fact Theorem 3 will follow from combining Theorem 2 with the following theorem which estimates the error between the time-discrete solution $u_m$ to (3.1) and the solution $u_{h,m}$ to (4.1).
Theorem 4 Let \( u_0 \in L^2(\Omega; W^{1,2}_{\text{div}}(\mathbb{T}^2)) \cap L^8(\Omega; L^2_{\text{div}}(\mathbb{T}^2)) \) be \( \mathcal{F}_0 \)-measurable and assume that \( \Phi \) satisfies (2.1). Let \( (u_m)_{m=1}^M \) be the solution to (3.1). Assume that \( L\Delta t \leq (-\varepsilon \log h)^{-1} \) for some \( L > 0 \). Then we have

\[
\mathbb{E} \left[ 1_{\Omega_h} \left( \max_{1 \leq m \leq M} \left\| u_m - u_{h,m} \right\|_{L^2_x}^2 + \Delta t \sum_{m=1}^M \left\| \nabla u_m - \nabla u_{h,m} \right\|_{L^2_x}^2 \right) \right] \leq c \left( h^2 + \Delta t \right),
\]

where \( (u_{h,m})_{m=1}^M \) is the solution to (4.1) with \( u_{h,0} = \Pi_h u_0 \). The constant \( c \) is (4.4) is independent of \( M \) and \( h \).

Remark 4 In the estimate of [9, Thm. 4.1] the error is estimated by \( h^{-3\varepsilon} (h^2 + (\Delta t) + h^2/\Delta t) \). By our refined pressure analysis we are able to get rid of the term \( h^2/\Delta t \) which leads to a restrictive assumption between space and time-discretization. Additionally, we can remove the factor \( h^{-3\varepsilon} \) arising from the convective term, see (4.6) below. Note that the error term \( h^2/\Delta t \) also appears in [10], where the finite-element based space-time discretization of the stochastic Stokes equations (that is the linearized version of (1.1) without convective term) is studied.

Proof of Theorem 4 Define the error \( e_{h,m} = u_m - u_{h,m} \). Subtracting (3.5) and (4.1) we obtain

\[
\int_{\mathbb{T}^2} e_{h,m} \cdot \phi \, dx + \Delta t \int_{\mathbb{T}^2} \mu \left( \nabla u_m - \nabla u_{h,m} \right) : \nabla \phi \, dx
\]

\[
= \int_{\mathbb{T}^2} e_{h,m-1} \cdot \phi \, dx - \Delta t \int_{\mathbb{T}^2} \left( (\nabla u_m)u_m - ((\nabla u_{h,m})u_{h,m-1} + (\text{div} u_{h,m-1})u_{h,m}) \right) \cdot \phi \, dx
\]

\[
+ \int_{\mathbb{T}^2} (\Phi(u_m) - \Phi(u_{h,m-1})) \Delta_m W \cdot \phi \, dx
\]

\[
- \int_{\mathbb{T}^2} \nabla \Delta^{-1} \text{div} \Phi(u_{m-1}) \Delta_m W \cdot \phi \, dx + \Delta t \int_{\mathbb{T}^2} \pi_m^{\text{det}} \text{div} \phi \, dx
\]

for every \( \phi \in V_{\text{div}}(\mathbb{T}^2) \). Setting \( \phi = \Pi_h e_{h,m} \) and applying the identity \( a \cdot (a - b) = \frac{1}{2} (|a|^2 - |b|^2 + |a - b|^2) \) (which holds for any \( a, b \in \mathbb{R}^n \)) we gain

\[
\int_{\mathbb{T}^2} \frac{1}{2} \left( |\Pi_h e_{h,m}|^2 - |\Pi_h e_{h,m-1}|^2 + |\Pi_h e_{h,m} - \Pi_h e_{h,m-1}|^2 \right) \, dx + \Delta t \int_{\mathbb{T}^2} \mu |\nabla e_{h,m}|^2 \, dx
\]

\[
= \Delta t \int_{\mathbb{T}^2} \mu \nabla e_{h,m} : \nabla (u_m - \Pi_h u_m) \, dx
\]

\[
- \Delta t \int_{\mathbb{T}^2} \left( (\nabla u_m)u_m - ((\nabla u_{h,m})u_{h,m-1} + (\text{div} u_{h,m-1})u_{h,m}) \right) \cdot \Pi_h e_{h,m} \, dx
\]

\[
+ \Delta t \int_{\mathbb{T}^2} \pi_m^{\text{det}} \text{div} \Pi_h e_{h,m} \, dx
\]

\[
+ \int_{\mathbb{T}^2} (\Phi(u_m) - \Phi(u_{h,m-1})) \Delta_m W \cdot \Pi_h e_{h,m} \, dx
\]

\[
- \int_{\mathbb{T}^2} \nabla \Delta^{-1} \text{div} \Phi(u_{m-1}) \Delta_m W \cdot \Pi_h e_{h,m} \, dx.
\]
= I_1(m) + \cdots + I_5(m). \quad (4.5)

Young’s inequality yields

\begin{align*}
I_1(m) &\leq \kappa \Delta t \int_{T^2} |\nabla e_{h,m}|^2 \, dx + c_k \Delta t \int_{T^2} |\nabla u_m - \nabla \Pi_h \nabla u_m|^2 \, dx \\
&\leq \kappa \Delta t \int_{T^2} |\nabla e_{h,m}|^2 \, dx + c_k h^2 \Delta t \int_{T^2} |\nabla^2 u_m|^2 \, dx.
\end{align*}

for every \( \kappa > 0 \) using also (2.15). The convective term \( I_2(m) \) can be decomposed as

\begin{align*}
I_2(m) &= I_2^1(m) + I_2^2(m) + I_2^3(m), \\
I_2^1(m) &= -\Delta t \int_{T^2} (\nabla e_{h,m}) u_{m-1} \cdot (u_m - \Pi_h u_m) \, dx, \\
I_2^2(m) &= \Delta t \int_{T^2} (\nabla e_{h,m}) e_{h,m-1} \cdot (u_m - \Pi_h u_m) \, dx \\
&\quad + \Delta t \int_{T^2} (\text{div} e_{h,m-1}) e_{h,m} \cdot (u_m - \Pi_h u_m) \, dx, \\
I_2^3(m) &= -\Delta t \int_{T^2} (\nabla \Pi_h e_{h,m}) e_{h,m-1} \cdot u_m \, dx \\
&\quad - \Delta t \int_{T^2} (\text{div} e_{h,m-1}) \Pi_h e_{h,m} \cdot u_m \, dx.
\end{align*}

As in [9, pages 2489–2491] we introduce the sample set

\[ \Omega_{h,m}^\varepsilon = \left\{ \omega \in \Omega \mid \max_{0 \leq n \leq m} \left( \| \nabla u_n \|_{L^2}^4 + \| u_{h,n} \|_{L^2}^2 \right) \leq -\varepsilon \log h \right\} \]

and obtain

\begin{align*}
1_{\Omega_{h,m-1}^\varepsilon} I_2^1(m) &\leq \kappa 1_{\Omega_{h,m-1}^\varepsilon} \left( \| \nabla e_{h,m-1} \|_{L^2}^2 + \| \nabla e_{h,m} \|_{L^2}^2 \right) \\
&\quad + c_k \Delta t h^4 \max_{1 \leq n \leq m} \| e_{h,n} \|_{L^2}^2 \| \nabla u_m \|_{L^2}^2 \| \nabla^2 u_m \|_{L^2}^2, \\
1_{\Omega_{h,m-1}^\varepsilon} I_2^2(m) &\leq \kappa 1_{\Omega_{h,m-1}^\varepsilon} \left( \| \nabla e_{h,m-1} \|_{L^2}^2 + \| \nabla e_{h,m} \|_{L^2}^2 \right) \\
&\quad + c_k \Delta t \log(h^{-\varepsilon}) \max_{1 \leq n \leq m} 1_{\Omega_{h,n-1}^\varepsilon} \| e_{h,n} \|_{L^2}^2 \\
&\quad + c_k \Delta t \| \nabla (u_m - u_{m-1}) \|_{L^2} \max_{1 \leq n \leq m} \| \nabla u_n \|_{L^2}^2 \max_{0 \leq n \leq m} \| e_{h,n} \|_{L^2}^2,
\end{align*}

where \( \kappa > 0 \) is arbitrary. For \( I_2^1(m) \), however, we get a slightly better estimate than in [9] since our definition of \( I_2^1(m) \) makes use of \( \text{div} u_m = 0 \). We obtain

\[ 1_{\Omega_{h,m}^\varepsilon} I_2^1(m) \leq \kappa 1_{\Omega_{h,m-1}^\varepsilon} \| \nabla e_{h,m} \|_{L^2}^2 + c_k h^3 \log(h^{-\varepsilon}) \| \nabla^2 u_m \|_{L^2}^2 \] \quad (4.6)
due to (2.14). The crucial point in this proof (making the essential difference to [9]) are the estimates for the pressure terms $I_3(m)$ and $I_5(m)$. We will estimate $I_3(m)$ first whereas $I_5(m)$ will only be bounded after iterating (4.5), see the estimates for $\mathcal{M}_{m,2}$ below. By (2.15) we have

\[
    I_3(m) = \Delta t \int_{\Omega} \nabla (\Pi_h^* - \Pi_h) \cdot \mathbf{u} \, dx \\
    \leq c_\kappa \Delta t \int_{\Omega} \nabla (\Pi_h^* - \Pi_h)^2 \, dx + \kappa \Delta t \int_{\Omega} \nabla \Pi_h \cdot \mathbf{u} \, dx \\
    \leq c_\kappa \Delta t h^2 \int_{\Omega} \nabla (\Pi_h^* - \Pi_h)^2 \, dx + c \Delta t \int_{\Omega} \nabla \Pi_h \cdot \mathbf{u} \, dx,
\]

where $\kappa > 0$ is arbitrary. Plugging all together and choosing $\kappa$ small enough (to absorb the corresponding terms to the left-hand side) we have shown

\[
    1_{\Omega_{h,m-1}} \left( \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx + \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h - \Pi_h \mathbf{e}_{h,m-1})^2 \, dx + \Delta t \int_{\Omega} \nabla \mathbf{e}_h \, dx \right) \\
    \leq 1_{\Omega_{h,m-1}^\varepsilon} \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx + c \Delta t \log(1 + \|\mathbf{u}_h\|_{L^2}) \left( \max_{1 \leq n \leq m} 1_{\Omega_{h,n-1}^\varepsilon} \|\mathbf{e}_{h,n}\|_{L^2} \right) \\
    + c \Delta t h^2 \left( \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx + \int_{\Omega} (1 + \|\mathbf{u}_h\|_{L^2}) \, dx \right) \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx \\
    + c \Delta t h^4 \left( \max_{1 \leq n \leq m} \|\mathbf{e}_{h,n}\|_{L^2}^2 \right) \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx \\
    + c \Delta t \int_{\Omega} \nabla (\mathbf{u}_h - \mathbf{u}_{h,m-1}) \, dx \left( \max_{1 \leq n \leq m} \int_{\Omega} \nabla \mathbf{u}_n \, dx \right) \left( \max_{1 \leq n \leq m} \int_{\Omega} \mathbf{e}_{h,n} \, dx \right) \\
    + c \int_{\Omega_{h,m-1}^\varepsilon} \left( \int_{t_{m-1}}^{t_m} \nabla \mathbf{u}_m \, dx \right) \cdot \Pi_h \mathbf{e}_h \, dx \\
    - c \int_{\Omega_{h,m-1}^\varepsilon} \left( \int_{t_{m-1}}^{t_m} \nabla \mathbf{u}_m \, dx \right) \cdot \Pi_h \mathbf{e}_h \, dx.
\]

Iterating this inequality yields

\[
    1_{\Omega_{h,m-1}^\varepsilon} \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx + \sum_{n=1}^{m} 1_{\Omega_{h,n-1}^\varepsilon} \left( \int_{\Omega} \nabla (\Pi_h \mathbf{e}_{h,n} - \Pi_h \mathbf{e}_{h,n-1})^2 \, dx + \Delta t \int_{\Omega} \nabla \mathbf{e}_{h,n} \, dx \right) \\
    \leq \int_{\Omega} \nabla (\mathbf{e}_{h,0})^2 \, dx + c \Delta t \log(1 + \|\mathbf{u}_h\|_{L^2}) \sum_{n=1}^{m} \left( \max_{1 \leq \ell \leq n} 1_{\Omega_{h,\ell-1}^\varepsilon} \|\mathbf{e}_{h,\ell}\|_{L^2} \right) \\
    + c h^2 \Delta t \sum_{n=1}^{m} \left( \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx + \int_{\Omega} (1 + \|\mathbf{u}_h\|_{L^2}) \, dx \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx \right) \\
    + c \Delta t h^4 \sum_{n=1}^{m} \left( \max_{1 \leq \ell \leq n} \|\mathbf{e}_{h,\ell}\|_{L^2}^2 \right) \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx \int_{\Omega} \nabla (\Pi_h \mathbf{e}_h)^2 \, dx.
\]
Now, we explain how to bound line by line in expectation. The error in the initial datum can be bounded by $h^2$ by (2.14) and the assumption $u_0 \in L^2(\Omega; W_{\text{div}}^{1,2}(\mathbb{T}^2))$. The second term on the right-hand side can be handled by the discrete Gronwall lemma using the assumption $L \Delta t \leq (-\varepsilon \log h)^{-1}$. The expectation of the second line is bounded by $h^2$ using Lemmas 3 and 4 (the estimate for $\nabla P_m$ is the first main ingredient in our proof). This estimate is better than the corresponding one in [9] as only the deterministic part of the pressure appears here. The expectation of the terms in the third line is bounded by

\[
\mathbb{E} \left[ \left( \max_{1 \leq \ell \leq M} \left\| e_{h,\ell} \right\|_{L^2_\ell}^2 \right) \left( \max_{1 \leq \ell \leq M} \left\| \nabla u_\ell \right\|_{L^2_\ell}^2 \right) \Delta t \sum_{n=1}^M \int_{\mathbb{T}^2} |\nabla^2 u_n|^2 \, dx \right]
\leq \left( \mathbb{E} \left[ \max_{1 \leq \ell \leq M} \left\| e_{h,\ell} \right\|_{L^2_\ell}^2 \right] \right)^\frac{1}{2} \left( \mathbb{E} \left[ \max_{1 \leq \ell \leq M} \left\| \nabla u_\ell \right\|_{L^2_\ell}^2 \right]^4 \right)^{\frac{1}{4}} \left( \mathbb{E} \left[ \Delta t \sum_{n=1}^M \int_{\mathbb{T}^2} |\nabla^2 u_n|^2 \, dx \right] \right)^{\frac{1}{4}}.
\]

This is uniformly bounded as a consequence of Lemmas 3 and 6. The fourth line is controlled by $\Delta t$ due to the estimate

\[
\mathbb{E} \left[ \sum_{n=1}^M \int_{\mathbb{T}^2} \mathbf{1}_{\Omega_{h,n-1}} \int_{I_n} \left( \Phi(u_{n-1}) - \Phi(u_{h,n-1}) \right) dW \cdot \Pi_h e_{h,n} \, dx \right]
\leq \left( \mathbb{E} \left[ \sum_{n=1}^M \int_{\mathbb{T}^2} \left| \nabla (u_n - u_{n-1}) \right|^2 \, dx \right] \right)^\frac{1}{2} \left( \mathbb{E} \left[ \max_{1 \leq \ell \leq M} \int_{\mathbb{T}^2} |\nabla u_\ell|^2 \, dx \right]^4 \right)^{\frac{1}{4}} \times \left( \mathbb{E} \left[ \max_{1 \leq \ell \leq M} \int_{\mathbb{T}^2} |e_{h,\ell}|^2 \, dx \right]^4 \right)^{\frac{1}{4}}
\]

and the uniform bounds from Lemmas 3 and 6 (with $q = 3$). It remains to estimate the two stochastic terms

\[
\mathcal{M}_{m,1} = \sum_{n=1}^M \mathbf{1}_{\Omega_{h,n-1}} \int_{\mathbb{T}^2} \int_{I_n} \left( \Phi(u_{n-1}) - \Phi(u_{h,n-1}) \right) dW \cdot \Pi_h e_{h,n} \, dx,
\]

\[
\mathcal{M}_{m,2} = \sum_{n=1}^M \mathbf{1}_{\Omega_{h,n-1}} \int_{\mathbb{T}^2} \int_{I_n} \left( \text{Id} - \Pi_h^\pi \right) \Delta^{-1} \text{div} \Phi(u_{n-1}) dW \, \text{div} \Pi_h e_{h,n} \, dx.
\]
Note that we used integration by parts and $\Pi_h e_{h,n} \in V^{\text{div}}_h(\Omega^2)$ together with the definition of $\Pi_h e_{h,n}$ to rewrite $\mathcal{M}_{m,2}$ into the form above. Finally, we write

$$\mathcal{M}_{m,1} = \sum_{n=1}^{m} \mathbf{1}_{\Omega_{h,n-1}} \int_{\mathbb{T}^2} \int_{t_{n-1}}^{t_n} (\Phi(u_{n-1}) - \Phi(u_{h,n-1})) \, dW \cdot \Pi_h e_{h,n-1} \, dx$$

$$+ \sum_{n=1}^{m} \mathbf{1}_{\Omega_{h,n-1}} \int_{\mathbb{T}^2} \int_{t_{n-1}}^{t_n} (\Phi(u_{n-1}) - \Phi(u_{h,n-1})) \, dW \cdot (\Pi_h e_{h,n} - \Pi_h e_{h,n-1}) \, dx$$

$$=: \mathcal{M}_{m,1}^1 + \mathcal{M}_{m,1}^2$$

as well as

$$\mathcal{M}_{m,2} = \sum_{n=1}^{m} \mathbf{1}_{\Omega_{h,n-1}} \int_{\mathbb{T}^2} \int_{t_{n-1}}^{t_n} (\text{Id} - \Pi_h^2) \Delta^{-1} \text{div} \Phi(u_{n-1}) \, dW \, \text{div} \Pi_h e_{h,n-1} \, dx$$

$$+ \sum_{n=1}^{m} \mathbf{1}_{\Omega_{h,n-1}} \int_{\mathbb{T}^2} \int_{t_{n-1}}^{t_n} (\text{Id} - \Pi_h^2) \Delta^{-1} \text{div} \Phi(u_{n-1}) \, dW \, \text{div}(\Pi_h e_{h,n} - \Pi_h e_{h,n-1}) \, dx$$

$$=: \mathcal{M}_{m,2}^1 + \mathcal{M}_{m,2}^2.$$

These representations have the advantage that $\mathcal{M}_{m,1}^1$ and $\mathcal{M}_{m,2}^2$ are martingales (note the index $n-1$ in the indicator functions). Consequently, we can apply the Burkholder–Davis–Gundy inequality to estimate them. As far as $\mathcal{M}_{m,1}$ is concerned we have

$$\mathbb{E} \left[ \max_{1 \leq m \leq M} \left| \mathcal{M}_{m,1}^1 \right| \right]$$

$$\leq c \mathbb{E} \left[ \sum_{0 \leq n \leq M} \mathbf{1}_{\Omega_{h,n}} \int_{t_{n-1}}^{t_n} \|\Phi(u_{n-1}) - \Phi(u_{h,n-1})\|_{L^2(\Omega)}^2 \, L^2(\Omega) \, dx \right]^{1/2}$$

$$\leq c \mathbb{E} \left[ \max_{0 \leq n \leq M} \mathbf{1}_{\Omega_{h,n}} \|\Pi_h e_{h,n}\|_{L^2(\Omega)}^2 \left( \sum_{n=1}^{M} \mathbf{1}_{\Omega_{h,n-1}} \int_{t_{n-1}}^{t_n} \|\Phi(u_{n-1}) - \Phi(u_{h,n-1})\|_{L^2(\Omega)}^2 \, dx \right)^{1/2} \right]$$

$$\leq \kappa \mathbb{E} \left[ \max_{0 \leq n \leq M} \mathbf{1}_{\Omega_{h,n}} \|\Pi_h e_{h,n}\|_{L^2(\Omega)}^2 \right] + c_\kappa \mathbb{E} \left[ \sum_{n=1}^{M} \mathbf{1}_{\Omega_{h,n-1}} \int_{t_{n-1}}^{t_n} \|u_{n-1} - u_{h,n-1}\|_{L^2(\Omega)}^2 \, dx \right]$$

$$\leq \kappa \mathbb{E} \left[ \max_{0 \leq n \leq M} \mathbf{1}_{\Omega_{h,n}} \|\Pi_h e_{h,n}\|_{L^2(\Omega)}^2 \right] + c_\kappa \mathbb{E} \left[ \Delta t \sum_{n=1}^{M} \mathbf{1}_{\Omega_{h,n-1}} \|\Pi_h e_{h,n-1}\|_{L^2(\Omega)}^2 \right]$$

$$+ \sum_{n=1}^{M} \mathbf{1}_{\Omega_{h,n-1}} \|u_{n-1} - \Pi_h u_{n-1}\|_{L^2(\Omega)}^2$$

Here, we also used (2.1) as well as Young’s inequality for $\kappa > 0$ arbitrary. Now, the first term can be absorbed for $\kappa$ small enough. The second term can be handled by the discrete Gronwall lemma (note that $\Omega_{h,n} \subset \Omega_{h,n-1}$ such that $\mathbf{1}_{\Omega_{h,n}} \leq \mathbf{1}_{\Omega_{h,n-1}}$ a.s.)
Using (2.14) the last term can be estimated by

\[ c_k h^2 \mathbb{E} \left[ \Delta t \sum_{n=1}^{M} \Omega_{h,n-1} \| \nabla u_{n-1} \|_{L^2}^2 \right] \]

which is bounded by \( ch^2 \) using Lemma 3 (recall that \( u_0 \in L^2(\Omega; W^{1,2}(T^2)) \)). For the term \( M_{m,1}^{2} \) we obtain by Cauchy–Schwartz inequality, Young’s inequality, Itô-isometry and (2.1)

\[
\mathbb{E} \left[ \max_{1 \leq m \leq M} | M_{m,1}^{1} | \right] \leq \kappa \mathbb{E} \left[ \sum_{n=1}^{M} \Omega_{h,n-1} \| \Pi_h e_h,n - \Pi_h e_{h,n-1} \|_{L^2}^2 \right] \\
+ c_k \mathbb{E} \left[ \sum_{n=1}^{M} \Omega_{h,n-1} \int_{t_{n-1}}^{t_n} (\Phi(u_{n-1}) - \Phi(u_{h,n-1})) \, dW \right]^2 \\
\leq \kappa \mathbb{E} \left[ \sum_{n=1}^{M} \Omega_{h,n-1} \| \Pi_h e_h,n - \Pi_h e_{h,n-1} \|_{L^2}^2 \right] \\
+ c_k \mathbb{E} \left[ \int_{t_{n-1}}^{t_n} \| u_{n-1} - u_{h,n-1} \|_{L^2}^2 \, dt \right].
\]

The first term can be absorbed for \( \kappa \) small enough whereas the second one can be estimated as for \( M_{m,1}^{1} \).

Now, we come to the second main ingredient which is the estimate for \( M_{m,2} \). We obtain using (2.17), (2.1) and continuity of \( \nabla^2 \Delta^{-1} \)

\[
\mathbb{E} \left[ \max_{1 \leq m \leq M} | M_{m,2}^{1} | \right] \\
\leq c \mathbb{E} \left[ \sum_{n=1}^{M} \Omega_{h,n-1} \int_{t_{n-1}}^{t_n} (|1 - \Pi_h^2| \Delta^{-1} \| \nabla \Phi(u_{n-1}) \|_{L^2(\Omega)}^2 \| \nabla \Pi_h e_{h,n-1} \|_{L^2}^2 \right]^{1/2} \\
\leq c h^2 \mathbb{E} \left[ \max_{1 \leq n \leq M} \| \nabla^2 \Delta^{-1} \|_{L^2(\Omega)} \| \nabla \Pi_h e_{h,n} \|_{L^2}^2 \right] \\
\leq c_k h^4 \mathbb{E} \left[ \max_{1 \leq n \leq M} \| \nabla u_{n-1} \|_{L^2}^2 \right] + \kappa \mathbb{E} \left[ \Delta t \sum_{n=1}^{M} \Omega_{h,n-1} \| \nabla \Pi_h e_{h,n} \|_{L^2}^2 \right].
\]

The first term is bounded by \( c_k h^4 \) using Lemmas 3 (recall that \( u_0 \in L^2(\Omega; W^{1,2}(T^2)) \)). The second term can be absorbed if \( \kappa \ll 1 \). As a consequence of Young’s inequality, inverse estimates on \( V^h(T^2) \), Itô-isometry and (2.17) we infer

\[
\mathbb{E} \left[ \max_{1 \leq m \leq M} | M_{m,2}^{2} | \right] \leq \kappa h^2 \mathbb{E} \left[ \sum_{n=1}^{M} \Omega_{h,n-1} \| \nabla (\Pi_h e_{h,n} - \Pi_h e_{h,n-1}) \|_{L^2}^2 \right].
\]
Convergence rates for the numerical approximation... 577

\[ + c_\kappa h^{-2} \mathbb{E} \left[ \sum_{n=1}^{M} 1_{\Omega_{h,n-1}} \left\| \int_{t_{n-1}}^{t_n} (\text{Id} - \Pi_h^2) \Delta^{-1} \text{div}\Phi(u_{n-1}) \, dW \right\|_{L^2}^2 \right] \]

\[ \leq c \kappa \mathbb{E} \left[ \sum_{n=1}^{M} 1_{\Omega_{h,n-1}} \left\| \Pi_h e_{h,n} - \Pi_h e_{h,n-1} \right\|_{L^2}^2 \right] \]

\[ + c_\kappa h^{-2} \mathbb{E} \left[ \sum_{n=1}^{M} 1_{\Omega_{h,n-1}} \left\| \int_{t_{n-1}}^{t_n} (\text{Id} - \Pi_h^2) \Delta^{-1} \text{div}\Phi(u_{n-1}) \right\|_{L^2(\Omega;L^2_x)}^2 \, dt \right] \]

\[ \leq c \kappa \mathbb{E} \left[ \sum_{n=1}^{M} 1_{\Omega_{h,n-1}} \left\| \Pi_h e_{h,n} - \Pi_h e_{h,n-1} \right\|_{L^2}^2 \right] \]

\[ + c_\kappa h^2 \mathbb{E} \left[ \sum_{n=1}^{M} \int_{t_{n-1}}^{t_n} \left\| \nabla^2 \Delta^{-1} \text{div}\Phi(u_{n-1}) \right\|_{L^2(\Omega;L^2_x)}^2 \, dt \right]. \]

The first term can be absorbed for \( \kappa \) small enough. Arguing as for \( \mathcal{M}_{m,2} \), the last term is bounded by \( c h^2 \mathbb{E} \left[ \max_{n} \left\| \nabla u_{n-1} \right\|_{L^2_x}^2 \right] \leq c h^2 \). Plugging all together and noting that \( \Omega_{h}^\varepsilon \subset \bigcup_{n=1}^{M} \Omega_{h,n}^\varepsilon \) shows

\[ \mathbb{E} \left[ 1_{\Omega_{h}^\varepsilon} \left( \max_{1 \leq m \leq M} \left\| \Pi_h e_{h,m} \right\|_{L^2_x}^2 + \Delta t \sum_{m=1}^{M} \left\| \nabla e_{h,m} \right\|_{L^2_x}^2 \right) \right] \leq c \left( h^2 + \Delta t \right). \]

Recalling that \( e_{h,m} = u_m - \Pi_h u_m + \Pi_h e_{h,m} \) and using (2.14) as well as Lemma 3 (a) gives the claim. \( \square \)
