Time Lumps in Nonlocal Stringy Models and Cosmological Applications

I. Ya. Aref’eva∗ and L. V. Joukovskaya†

ABSTRACT: We study lump solutions in nonlocal toy models and their cosmological applications. These models are motivated by a description of D-brane decay within string field theory framework. In order to find cosmological solutions we use the simplest local approximation keeping only second derivative terms in nonlocal dynamics. We study validity of this approximation in flat background where time lump solutions can be written explicitly and work out the validity of this approximation. Finally, we show that our models at large time exhibit the phantom behaviour similar to the case of the string kink.

1. Introduction

In the last years strings and D-branes attracted cosmological applications related with the
cosmological acceleration [1]-[5]. The observations suggest that the Universe is presently
accelerating [6, 7]. It is believed that a new physics is required to explain this phenomenon.
The bulk of energy density in the Universe is gravitationally repulsive and can be repre-
sented as an unknown form of energy (dark energy) with negative pressure and

\[ w = \frac{p}{\rho} \]

The current experimental data show that \( w \) lies in the range \( -1.61 < w < -0.78 \) [8, 14, 15]. There are various theoretical models – a quintessence scalar field [11], Dirac-Born-Infeld action [1]-[3], and other which are able
to describe the case \( w > -1 \).

The most exciting possibility would be the case \( w < -1 \) (see [11]-[23], [3] and references therein). There are several phenomenological models describing this phantom Universe [13, 15]. In these models week energy conditions \( \rho > 0, \rho + p > 0 \) are violated and most of them are unstable and strange phenomena related with unstability appear [7]. There are also models related with modified gravity [24], but there is a problem of getting these models basing on fundamental principles.
Recently it was shown that the string field theory (SFT) description of D-brane decay leads at large times to an effective phantom model [5]. As a result of this decay the spectrum becomes stable and the model does not suffer from instability problems. D-brane decay in non-flat metric within the SFT framework is described by the string tachyon action [5]

\[ S = \int \sqrt{-g} d^4 x \left( \frac{\alpha'}{16\pi G} R + \frac{1}{g_0^2} \left( -\kappa^2 g^{\mu\nu} \partial_\mu \phi \partial_\nu \phi + \frac{1}{2} \phi^2 - U(\Phi) \right) \right), \tag{1.1} \]

Here it is supposed that we deal with 3-dimensional D-brane, \( G \) is a 4–dimensional gravitational constant, \( \alpha' \) is a string tension, \( g_{\mu\nu} \) is a metric for dimensionless coordinates, \( R \) is a curvature, \( g_0 \) is a dimensionless string coupling constant, fields \( \phi \) and \( \Phi \) are dimensionless fields related via

\[ \Phi = \exp\left( \frac{\beta}{2} \Box_g \right) \phi, \quad \Box_g = \frac{1}{\sqrt{-g}} \partial_\mu \sqrt{-g} g^{\mu\nu} \partial_\nu, \tag{1.2} \]

\( \beta \) and \( \kappa^2 \) are constants whose values depend on the type of a string under consideration. The form of the potential also depends on the type of a string.

Action (1.1) in the Friedmann background

\[ ds^2 = -dt^2 + a^2(t)(dx_1^2 + dx_2^2 + dx_3^2), \tag{1.3} \]

gives Friedman equations and the equation for the field \( \Phi = \Phi(t) \) which in turn reads as

\[ (\kappa^2 \mathcal{D} + 1) e^{-\beta \mathcal{D}} \Phi = U'(\Phi), \tag{1.4} \]

where \( \mathcal{D} = -\partial_t^2 - 3H(t) \partial_t, \) \( H = \dot{a}/a \) is a Hubble parameter and \( U'(\Phi) = \partial U/\partial \Phi. \)

To study solutions of equation (1.4) the following approximation was used

\[ (\kappa^2 + \beta \kappa_0^2) (\ddot{\Phi} + 3H \dot{\Phi}) = V'(\Phi), \tag{1.5} \]
\[ V(\Phi) = U(\Phi) - \frac{1}{2} \Phi^2, \tag{1.6} \]

\( \kappa_0^2 \) is a parameter close to 1. This second order derivatives approximation is called mechanical or local approximation. In a rather rough approximation one can take \( \kappa_0^2 \simeq 1 \) (a so-called direct mechanical approximation).

For \( \beta \kappa_0^2 > \kappa^2 \) we get ghost kinetic term in (1.5). For this case after time rescaling we can take \( \beta \kappa_0^2 - \kappa^2 = 1 \). This case corresponds to a phantom model. The dynamics of the phantom model in the flat background reproduces dynamics of the usual particle in the overturn potential [35]. The equation of state parameter \( w \) for the phantom in a general potential can be represented as

\[ w = -1 - \frac{1}{3m_p^2 H^2}, \tag{1.7} \]

where \( m_p^2 \) is a dimensionless parameter related with the Plank mass \( M_p^2, \) \( m_p^2 = M_p^2 \alpha' = \alpha'/8\pi G. \)

For a cubic potential \( U \) the action (1.1) is the curved version of the action for the tachyon field in the Witten SFT [25] at the lowest order in the level truncation scheme
It is supposed that we deal with 3-dimensional D-brane in 26-dimensional space-time and the volume of compactified 22-dimensional space in (1.1) is omitted.

For a quartic $U$ the action (1.1) is the curved version of the action for the tachyon field which was obtained in an approximation of slow varying auxiliary field \cite{28} from cubic fermionic SFT \cite{28}. This action in the flat case has been obtained for the case when the string field contains only two fields: the tachyon in the GSO(-) sector\footnote{To produce nonBPS-branes the GSO(-) sector is involved \cite{29,30} (see reviews \cite{31}-\cite{33} for details).} and a lowest auxiliary field in the GSO(+) sector. Integration over this auxiliary field produces a fourth degree of the tachyon self interaction.

The existence of the kink solution for the flat version of equation (1.4) with $\kappa = 0$ has been shown numerically in \cite{37} and has been proved in \cite{39}. A validity of the approximation (1.5) for this kink solution has been studied in \cite{38}.

In the case of the flat metric and $\kappa = 0$ the kink solution of (1.4) is a monotonic function interpolating between two different vacuum solutions. However not only monotonic kink solutions appear in the dynamics of string tachyons. For $\kappa \neq 0, \kappa^2 < \beta \kappa_0^2$ and $H = 0$ there are non-monotonic kink solutions of (1.4) and these solutions have bounce points. In the open-closed string model \cite{40} a bounce point also appears \cite{41}. Typical examples of solutions with one bounce point are lump solutions. In particular, such type of solutions has been recently found in \cite{42}.

In this paper we consider two SFT inspired models with the action (1.1). For the first model
\begin{equation}
U = \frac{\sqrt{k}}{k+1} \Phi^{k+1}, \quad k < 1, \tag{1.8}
\end{equation}
and for the second model the potential is a special polynomial
\begin{equation}
U = \sum_{n=1}^{N} \frac{\alpha_n}{n+1} \Phi^{n+1} \tag{1.9}
\end{equation}

Distinguished feature of these models is that they have explicit lump solutions for $\kappa = 0$ in flat background. We study a validity of the mechanical approximation to these solutions. For this purpose we compare essential physical characteristics such as energy and pressure of the nonlocal systems with their mechanical analogues. We find that under special conditions these characteristics in both models are rather similar. Also in both cases it is possible to find small explicit modifications of the mechanical potentials to solve corresponding local equations in the Friedmann metric.

The paper is organized as follows. In Section 2 we consider the equation of motion
\begin{equation}
e^{\beta \partial_t^2} \Phi = \sqrt{k} \Phi^k. \tag{1.10}
\end{equation}
where $0 < k < 1, a > 0$. There is the lump solution to this equation
\begin{equation}
\Phi(t) = e^{-\xi t^2}, \quad \xi = \frac{1-k}{4\beta k}, \tag{1.11}
\end{equation}
The energy of the solution (1.11) is equal to zero.
In Section 2.2 we compare (1.11) with zero energy periodic trajectories in the direct mechanical approximation of (1.5). The period $T_k$ becomes large when $k \to 1$. We show that for time $t < T_k/2$ the zero-energy periodic solutions to the mechanical problem rather well approximate the lump solution (1.11).

In Section 2.3 we calculate explicitly the pressure on the solution (1.11) and in Section 2.4 compare it with the pressure of the zero-energy periodic solution of the mechanical problem for $|t| < T_k$. We find that the mechanical approximation represents a behavior of the pressure of the non local problem with a good degree of accuracy for $k$ closed to 1, $k < 1$. We also compare $Φ$ with $Φ = e^{β/2} Φ$ and conclude that a comparison of $Φ$ and $\tilde{Φ}$ gives a rather good quantitative criterium for a validity of the local approximation. A precise condition of a validity of the local approximation is a condition that the magnitude of $\tilde{Φ} - Φ - \frac{2}{β} \frac{∂^2}{∂t^2} Φ$ is small.

In Section 3.1 we consider a modified integral equation with the constant friction $e^{β} \frac{∂^2}{∂t^2} Φ + h \frac{∂}{∂t} Φ = \sqrt{kg(t)} Φ_k^h$. (1.12) has an explicit lump solution

$$Φ_h(t) = e^{-ξt^2 + B t}, \quad B = \frac{h}{2β}(1 - \sqrt{1 + 16ξβ^2}),$$

(1.13)

We see that the friction makes behavior of the solutions of the nonlocal equation more closed to that of the corresponding mechanical problem. This give us a possibility to use this approximation for Friedmann equations.

In Section 3.2 we study numerically the corresponding Friedmann equations and find that there is a regime, i.e. suitable initial conditions, that represents an acceleration with $w < -1$.

In Section 3.3 we reconstruct explicitly the potential for which (1.11) is an exact solution of the Friedman equations. This potential has the form

$$V(Φ) = V_0(Φ) + V_1(Φ),$$

(1.14)

where

$$V_0(Φ) = -2ξ Φ^2 \log Φ,$$

(1.15)

and $δV(Φ)$ is of order of $1/m_p^2$.

$$V_1(Φ) = \frac{3ξ}{64m_p^2} \left( \sqrt{2π e r f(\sqrt{-2 log Φ})} - 4Φ^2 \sqrt{-log Φ} \right)^2.$$

In Section 4 we search for lump solutions of the following equation

$$e^{β} Φ = \sum_{n=1}^{N} α_n Φ^n$$

(1.16)

where $α_n$ are constant. It is know that a direct numerical search for lumps solutions is a rather difficult problem. There are also nonexistence theorems for a wide class of
potentials\cite{36,39}. It is also interesting to find lump as well as kink solutions in vacuum SFT\cite{43,44}.

Here we accept the following strategy. We start from a given function

$$\varphi_0(t) = \text{sech}^2(t)$$

(1.17)

and find constant $\alpha_n$ from a requirement that the function (1.17) is a solution to equation (1.16) with a small discrepancy for fixed $N$. We mean that the discrepancy has a small $L_2$-norm. We consider the cases $N = 3, \ldots, 14$. Qualitatively one can say that lowest coefficients $\alpha_n$ show a stable picture when $N \to \infty$. With the obtained $\alpha_n$ in Section 4.2 we find numerical solutions to (1.16) with zero energy using an analog of Freedman method (see \cite{41} and references therein).

Then in Section 4.3 we study a mechanical approximation to equation (1.16). It occurs that all potentials $V$ have local maximum at $\Phi = 0$ and are equal to zero at $\Phi_{0N}, \Phi_{0N} < 1$ and $\Phi_{0N-1} \approx \Phi_{0N}$. As has been mentioned above, the lowest coefficients $\alpha_n$ are stabilized as $N \to \infty$. For the zero-energy solutions of the mechanical problem with the initial data $\Phi(0) = \Phi_{0N}$ one has $|\Phi(t)| < 1$ and for such $\Phi$ only the low-order coefficients dominate in the potential. Therefore, in spite of global change of the behavior of potentials with $N$ increasing, the form of potentials near the region, where the particle with the above initial data moves, does not change. For small time trajectories of the mechanical problems with above mentioned initial data do not reproduce the lump (1.17) since $\text{sech}^2(t)$ has derivatives of the same order as itself. However for large time when trajectories are closed to an attractor point $\Phi = 0$ they are also closed to the lump.

The profile of the potential (1.6) with found $\alpha_n$ in the region $0 < \Phi < 1$ is rather closed to the profile of the potential

$$V_0(\Phi) = 2(1 - \Phi)\Phi^2$$

(1.18)

for which the function (1.17) solves the mechanical problem with the lump boundary conditions. In Section 4.5 we show that engaging of the Friedmann metric modifies the potential (1.18) and one has to add

$$V_1 = -\frac{4}{75m_p^2}(-1 + \Phi)^3(2 + 3\Phi)^2$$

to (1.18) in order the function (1.17) to be a solution of the Friedmann equations.

2. Gaussian Lump

2.1 Action and equation of motion

In this section we consider the action

$$S = \int d^4x \left[\frac{1}{2}\phi^2 - \frac{\sqrt{k}}{k + 1} \Phi^{k+1}\right],$$

(2.1)
with an unusual non-polynomial interaction

\[ 0 < k < 1 \]  

and where \( \Box = -\partial^2 + \nabla^2 \),

\[ \Phi(x) = e^{\frac{\beta}{2}\Box} \phi(x), \quad a > 0, \]  

The equation of motion for this action is

\[ e^{-\beta \Box} \Phi(x) = \sqrt{k} \Phi^k. \]  

For space homogeneous configurations \( \Phi = \Phi(t) \) it takes the form

\[ e^{\beta \partial^2} \Phi(t) = \sqrt{k} \Phi^k(t), \]  

here and below \( \partial = \partial_t \).

Equation (2.4) has the following solution

\[ \Phi(t) = e^{-\frac{1}{2} t^2}, \quad b = \frac{1 - k}{k} \]  

The relation between \( \Phi \) and \( \phi \) is

\[ \Phi(t) = e^{-\frac{\beta}{2} \partial^2} \phi(t) \]  

and one can get \( \phi \) from \( \Phi \) using the smoothing integral representation

\[ \phi(t) = \frac{1}{\sqrt{2\pi}} \int e^{-\frac{(t-t')^2}{2\beta}} \Phi(t')dt' \]  

Substituting (2.6) into (2.8) one gets smoothed solution \( \phi \)

\[ \phi(t) = \frac{\sqrt{2}}{\sqrt{2 + b}} e^{-\frac{b}{2(2+b)t^2}}. \]  

Fig. 1: Solutions of integral equation (2.3): 1) for \( \beta = \frac{1}{4}, k = 0.2 \); 2) for \( \beta = \frac{1}{4}, k = 0.8 \). The firm line is \( \Phi \) and the dashing line is \( \phi \).

From (2.6) and (2.9) we see that \( \Phi \) and \( \phi \) are related as

\[ \phi(t) = \sqrt{c} \Phi(\sqrt{c} t), \quad \text{where } c = \frac{2k}{1 + k} \]  

When \( k \to 1, c \to 1 \) and therefore \( \phi \approx \Phi^2 \) and when \( k \to 0, c \to 0 \) and \( \phi \approx 0 \). This is illustrated on Fig. 1 where solutions of (2.3) and corresponding smoothed fields \( \phi \) are presented for different values of \( k \).

\footnote{Let us note that in the more complicated model [40] \( c_2 = 13 \) it is known, that physical (analog of \( \phi \)) and tilded (analog of \( \Phi \)) fields coincide with very high precision [41].}
2.2 Mechanical approximation

Let us consider the mechanical approximation for equation (2.5),

$$\beta \ddot{\varphi}(t) = -V_{ot}(\varphi),$$  \hspace{1cm} (2.11)

the parameter $\beta$ plays a role of mass of the particle. The potential $V_{ot}$ is an overturn version of the potential (1.6) for $U$ given by (1.8),

$$V_{ot}(\varphi) = -V(\varphi), \quad V(\varphi) = \frac{\sqrt{k}}{k+1} \varphi^{k+1} - \frac{1}{2} \varphi^2,$$  \hspace{1cm} (2.12)

To have a real potential $V$ in (2.12) let us assume that $k = 1 - 2\delta$ and present the corresponding square in $U$ as $(\Phi^2)^{1/(1 - \delta)}$. In this case the potential $V_{ot}(\Phi)$ is an even function and this function is equal to zero at $\Phi = 0$ and has beak with singular second derivative $\Phi = 0$, see Fig.2.a. The particle with the zero energy oscillates between the point $\varphi = 0$ and the bounce at $\varphi_{max} = (2\sqrt{\frac{k}{k+1}})^{1/\delta}$. The zero-energy trajectories are presented in the fig.2.b and the exact lumps (2.6) are presented on fig.2.c for different $k$.

![Fig. 2: a) The potential $V$ for the $k=0.2$ (dashing line) and for $k=0.8$ (firm line). b) The numerical solution of equation (2.11) for $k=0.2$ (dashing line) and for $k = 0.8$ (firm line). c) Exact solution to integral equation (2.5) for $\beta = 1/4$ and $k= 0.2$ (dashing line) and $k=0.8$ (firm line).](image)

The periods of these motions are

$$T_k = \sqrt{\beta} \int_0^{\varphi_{max}} \frac{d\varphi}{\sqrt{-2V_{ot}}},$$  \hspace{1cm} (2.13)

In the table below we enumerate values of $T$ for different $k$ and $\beta = 1/4$.

| $k$   | $1/5$ | $1/3$ | $1/2$ | $2/3$ | $8/9$ | $9/10$ |
|-------|-------|-------|-------|-------|-------|--------|
| $T$   | $5\pi/4$ | $3\pi/2$ | $2\pi$ | $3\pi$ | $9\pi$ | $10\pi$ |

The solutions of the integral equations (2.5)(see Fig. 4.c) and their mechanical analogs (2.11) describe different physical behavior. Namely, the solution (2.6) of the integral equation starts from zero go above the bounce point $\varphi_{max}$ then rises $\Phi = 1$ and returns to zero. Thus the solution of the integral equation does not bounded by the bounce point, whereas the zero-energy solution of the mechanical model presents a periodic motion between the bounce point and zero. The period depends on $k$ and as $k$ goes to 1 the period becomes infinite, i.e. $k = 1$ corresponds to the free motion. Therefore, for small $k << 1$ the mechanical approximation does not work, while it works for $t < T_k$ for $k$ goes to 1.
2.3 Energy and pressure

In this subsection we consider the energy and the pressure of the nonlocal problem (2.5) and compare them with energy and pressure of the corresponding mechanical problem (2.11). Equation (2.4) has the conserved energy (compare with [35]):

\[ E = E_p + E_{nl1} + E_{nl2}, \]  

(2.14)

where

\[ E_p = -\frac{1}{2} \phi^2 + \frac{\sqrt{k}}{k+1} \Phi^{k+1}, \]  

(2.15)

\[ E_{nl1} = \frac{\beta}{2} \int_0^1 \left( e^{-\frac{\beta}{2} \rho^2 \sqrt{k} \Phi} \right) (e^{\frac{\beta}{2} \rho^2 \partial^2 \Phi}) d\rho \]  

(2.16)

and

\[ E_{nl2} = -\frac{\beta}{2} \int_0^1 \left( (e^{-\frac{\beta}{2} \rho^2 \sqrt{k} \Phi}) (e^{\frac{\beta}{2} \rho^2 \partial^2 \Phi}) \right) d\rho. \]  

(2.17)

One can see that this energy conserves. Indeed,

\[ \frac{dE(t)}{dt} = -\phi \partial \phi + \sqrt{k} \Phi \partial \Phi + \frac{\beta}{2} \int_0^1 \left( e^{-\frac{\beta}{2} \rho^2 \sqrt{k} \Phi} \right) \partial \left( e^{\frac{\beta}{2} \rho^2 \partial^2 \Phi} \right) d\rho \]

\[ = -\phi \partial \phi + \sqrt{k} \Phi \partial \Phi - \sqrt{k} \Phi e^{-\frac{\beta}{2} \rho^2 \partial^2 \Phi} \partial \phi - \phi + e^{-\frac{\beta}{2} \rho^2 \sqrt{k} \Phi} = 0. \]

The pressure in the model (2.1) has the form

\[ P = E_{nl2} - E_p - E_{nl1} \]  

(2.18)

Substituting in this formula expressions for \( E_{nl1} \) and \( E_{nl2} \) given by (2.16) and (2.17) one gets

\[ P = -\beta \int_0^1 \left( (e^{(2-\rho^2) \frac{\beta}{2} \rho^2 \partial^2 \Phi}) (e^{\frac{\beta}{2} \rho^2 \partial^2 \Phi}) \right) d\rho \]  

(2.19)

Substituting in (2.19) the explicit form of the solution (2.6) we get

\[ P = -\frac{2b^2 t^2}{\beta} \int_0^1 \frac{d\rho}{[(2-b(\rho-2))(2+b)]^{\frac{1}{2}}} \exp\left( -\frac{t^2}{\beta} \frac{b(2+b)}{4+4b-b^2(\rho-2)^2} \right), \]  

(2.20)

From formula (2.20) we see that the pressure is negative and for large time goes to zero.

2.4 Compression of pressure for nonlocal and local problems

Comparing expressions (2.14) and (2.18) with standard expressions of the energy and pressure for a scalar field, \( E_\phi = \frac{1}{2} \dot{\phi}^2 + V(\phi) \), \( P_\phi = \frac{1}{2} \dot{\phi}^2 - V(\phi) \), one can say that \( E_{nl1} \) and \( E_{nl2} \) play roles of extra terms in the nonlocal "kinetic" energy \( E_k \) and 'potential' energy \( E_p \), i.e.

\[ E = E_k + E_p \]  

(2.21)

\[ P = E_k - E_p \]  

(2.22)
\[ E_k = E_{nl_2} \quad (2.23) \]
\[ E_p = E_p + E_{nl_1} \quad (2.24) \]

where \( E_p \) and \( E_{nl_1}, E_{nl_2} \) are given by \( \text{Eq. (2.15-2.17)} \).

On the solution \( \text{Eq. (2.6)} \) we can write explicitly \( E_p, E_{nl_1} \) and \( E_{nl_2} \) as functions of time. These functions are presented on Fig.3 for particular value of parameters \( \beta = 1/4, k = 0.8 \) and \( k = 0.2 \). Time dependence of \( E_p \) and \( E_k \) is also presented on Fig. 3.

From Fig.3 we see that \( E_p \geq 0 \) and \( E_k \leq 0 \) for \( 0 \leq t < \infty \). Since the energy is conserved and equal to 0 and the pressure is \( 2E_k \leq 0 \).

Representing \( \text{Eq. (2.16)} \) and \( \text{Eq. (2.17)} \) as

\[ E_{nl_1} = \frac{\beta}{2} \int_0^1 (e^{\beta(1-\frac{\rho}{2})\partial^2 \Phi})(e^{\frac{\partial}{\rho}\partial^2 \partial \Phi})d\rho \quad (2.25) \]

and

\[ E_{nl_2} = -\frac{\beta}{2} \int_0^1 ((e^{\beta(1-\frac{\rho}{2})\partial^2 \Phi}))(e^{\frac{\partial}{\rho}\partial^2 \partial \Phi})d\rho. \quad (2.26) \]

we can see that in the approximation neglecting high order derivatives one has

\[ E_{nl_2} \sim -\frac{\beta}{2} \Phi^2, \quad (2.27) \]
\[ E_{nl_1} \sim \frac{\beta}{2} \Phi \ddot{\Phi}, \quad (2.28) \]

The discrepancy in these approximations are illustrated on the fig. 4. We see that the discrepancy becomes smaller when \( k \rightarrow 1 \).
Fig. 4: On the left pictures (1a and 2a) the dashing lines present the exact expressions $E_{nl_1}$ and the firm lines present the approximations to $E_{nl_1}$. On the right pictures (1b and 2b) the dashing lines present the exact expressions $E_{nl_2}$ and the firm lines present the approximations to $E_{nl_2}$. On 1a and 1b $k = 0.8$, $\beta = 1/4$ and on 2a and 2b $k = 0.2$, $\beta = 1/4$.

In this approximation

$$E_k \approx -\frac{\beta}{2} \Phi^2$$

$$E_p \approx -\frac{1}{2} \Phi^2 + \frac{\sqrt{k}}{k+1} \Phi^{k+1} + \frac{\beta}{2} \Phi \ddot{\Phi}$$

(2.29)  (2.30)

Taking into account that in this approximation

$$-\frac{1}{2} \Phi^2 \approx -\frac{1}{2} \Phi^2 - \frac{\beta}{2} \Phi \ddot{\Phi}$$

(2.31)

we get

$$E_p \approx -\frac{1}{2} \Phi^2 + \frac{\sqrt{k}}{k+1} \Phi^{k+1} \equiv V(\Phi)$$

(2.32)

So we see that the approximated kinetic term $E_k$ (2.29) and potential $E_p$ (2.32) coincide up to the sign with the kinetic and potential energy for the mechanical problem (2.11).

On Fig. 5 the kinetic and potential parts of the energy for the local problem (2.11) as functions of time are compared with $E_k$ and $E_n$ calculated on the solution (2.6). We see that for $k \to 1$ the kinetic and potential parts for local and nonlocal problems almost coincide for time $0 < t < T_k$. 
3. Perturbations of Gaussian Lump

3.1 Perturbation by the friction

Let us consider the integral equation with the constant friction and time depending coupling constant

$$e^{\beta \dot{\phi}^2 + h \dot{\phi}} \Phi_h = \sqrt{k} g(t) \Phi_h^k.$$  

For the case of a special time-depending coupling constant,

$$g(t) = e^{-2h(1-k)t},$$

there is the following lump solution

$$\Phi_h(t) = e^{-\frac{h}{2\beta} t^2 + Bt}, \quad B = \frac{h}{2\beta} (-1 - \sqrt{1 + 4\beta b})$$  

Using the following integral representation

$$e^{\beta \dot{\phi}^2 + h \dot{\phi}} \Phi(t) = \frac{1}{\sqrt{4\pi \beta}} \int e^{\frac{(t-t')^2}{4\beta}} \Phi(t') dt'.$$  

one can check that (3.2) solves (3.1)

Let us consider the mechanical problem with a friction that approximates equation (2.3),

$$\beta \ddot{\varphi}(t) + h\dot{\varphi}(t) + \varphi(t) = g(t) \sqrt{k} \varphi(t)^k,$$  

The particle with the zero energy starts from the point $\varphi_{max} = (\frac{2\sqrt{k}}{1+k})^{\frac{1}{1-k}}$ and moves to $\varphi_0 = 0$, but do not reach it. The corresponding trajectories are presented in the fig. 2.b for different $k$ and on fig. 2.c are presented the exact lumps (2.6) for different $k$. 

Fig. 5: Local kinetic (dashing positive line) and potential (dashing negative line) parts of the energy on zero-energy solutions of eq. (2.11) as functions of time. Nonlocal kinetic (firm negative line) and potential parts (firm positive line) of the energy on the solutions (2.6); the picture for k=0.8 (a) and k=0.2 (b).
Fig. 6: a) The numerical solution of equation (3.4) for $k=0.2$ (down solid line) and for $k=0.8$ (upper solid line) and exact solution to integral equation (2.5) for $\beta = 1/4$ and $k=0.2$ (down dot line) and $k=0.8$ (upper dot line), $h=0.5$; b) the numerical solution of equation (3.4) for $k=0.2$ (upper solid line) and for $k=0.8$ (down solid line) and exact solution to integral equation (2.5) for $\beta = 1/4$ and $k=0.2$ (down dot line) and $k=0.8$ (upper dot line), $h=0.1$

We see that the friction makes behavior of the solutions of the nonlocal equation more closed to that of the corresponding mechanical problem.

### 3.2 Perturbation by non flat metric

Let us now consider an interaction of the theory (2.1) with the gravity

$$S = \int \sqrt{-g} d^4x \left( \frac{m_p^2}{2} R + \frac{1}{2} \phi^2 - \frac{\sqrt{k}}{k+1} \Phi^{k+1} \right).$$

(3.5)

where

$$\Phi = \exp \left( \frac{\beta}{2} \Box_g \phi \right), \quad \Box_g = \frac{1}{\sqrt{-g}} \partial_{\mu} \sqrt{-g} g^{\mu\nu} \partial_{\nu}$$

(3.6)

On space homogeneous configurations in the Friedmann metric (1.3) the field equation takes the form

$$e^{\beta D} \Phi(t) = \sqrt{k} \Phi^k(t)$$

(3.7)

where $D = -\partial_t^2 - 3H(t)\partial_t$ and $H(t) = \dot{a}/a$, $\dot{a} = \partial_t a$. The Einstein equations have the form

$$3H^2 = \frac{1}{m_p^2} \rho$$

(3.8)

$$H^2 + 2\dot{a}/a = -\frac{1}{m_p^2} p$$

(3.9)

with the energy and pressure densities are given by

$$\rho = -\frac{1}{2} (e^{-\frac{\beta}{2}D}) \Phi^2 + \frac{\sqrt{k}}{k+1} \Phi^{k+1} + \mathcal{E}_1 + \mathcal{E}_2$$

(3.10)

$$p = 2\mathcal{E}_2$$

(3.11)

where

$$\mathcal{E}_1 = -\frac{\beta}{2} \int_0^1 d\tau (e^{\frac{\beta}{2}rD} \sqrt{k} \Phi^k) D(e^{-\frac{\beta}{2}rD} \Phi)$$

(3.12)
\[ E_2 = -\frac{\beta}{2} \int_0^1 d\tau (e^{\frac{\beta}{2} \mathcal{D}\partial \sqrt{k} \Phi^k})(e^{-\frac{\beta}{2} \mathcal{D}\partial \Phi}) \] (3.13)

Motivated by the flat case we make the following approximation

\[ \exp(\frac{\partial_t^2 + 3H(t)\partial_t}{1 + \partial_t^2 + 3H(t)\partial_t}) \Phi \approx (1 + \partial_t^2 + 3H(t)\partial_t) \Phi \] (3.14)

The corresponding Friedmann equations have the form (3.10), (3.11) with

\[ \rho = -\frac{1}{2} \dot{\varphi}^2 + V(\varphi), \] (3.15)

\[ p = -\frac{1}{2} \dot{\varphi}^2 - V(\varphi) \] (3.16)

and the equation for \( \varphi \) reads

\[ \ddot{\varphi} + 3H \dot{\varphi} = V'_\varphi \] (3.17)

Here \( V \) is given by (2.12)

![Fig. 7: a) \( \Phi \) as function on \( t \) with the initial condition \( \varphi(0) = 0.642 \) and \( \varphi'(0) = 0 \); b) function \( H = H(t) \) as function on \( t \); c) \( w = w(t) \) as function on \( t \).](image)

An numerically solution of the system of equations (3.15) and (3.17) for the potential (2.12) is presented on Fig. 7.

### 3.3 Exact Gaussian Lump Solution in Friedman Metric

In section 2 we have analyzed the solution for the phantom field with fractional interaction in the Friedman metric. Here we shall construct the potential which leads to exact gaussian lump-type solution (2.6). It is known that if one has an explicit solution for the space-homogeneous scalar field then one can reconstruct the form of potential (3.14). To realize this one assumes that the Hubble parameter \( H(t) \) has the special form

\[ H(t) = W(\phi(t)) \] (3.18)

where \( W \) is a function called superpotential. Substituting the anzats (3.18) in the Friedmann equation \( \dot{H} = \dot{\phi}^2/2m_p^2 \) we get

\[ 2m_p^2W' = \dot{\phi} \] (3.19)

where prime denotes derivatives in \( \phi \). For the gaussian lump solutions we have

\[ \dot{\phi} = -2\phi\sqrt{-\xi \ln \phi}, \] (3.20)
that gives the equation
\[ 2M_p^2 W' = -2\phi\sqrt{-\xi\ln\phi}, \quad (3.21) \]

from which we reconstruct the superpotential
\[ W(\phi) = -\frac{1}{2M_p^2} \phi^2 \sqrt{-\xi\ln\phi} + \frac{\sqrt{2\pi} \xi}{8m_p^2} \text{erf}(\sqrt{-2\log\phi}) \quad (3.22) \]

The potential is obtained from the second Friedmann equation, \( V(\phi) = 1/2\dot{\phi}^2 + 3m_p^2 W^2 \), and
\[ V(\phi) = -2\xi\phi^2 \log\phi + \frac{3\xi}{64m_p^2} \left( \sqrt{2\pi} \text{erf}(\sqrt{-2\log\phi}) - 4\phi^2 \sqrt{-\log\phi} \right)^2 \quad (3.23) \]

Fig. 8: a) The overturn potential \(-V\), b) \( H = H(t) \) as function on \( t \); c) \( w = w(t) \) as function on \( t \) and the line \( w = -1 \)

The Hubble parameter has the form
\[ H(t) = -\frac{1}{8m_p^2} \left( 4t\xi e^{-2t^2\xi} - \sqrt{2\pi} \text{erf}(\sqrt{2t\xi}) \right) \quad (3.24) \]

The asymptotic behavior of the Hubble parameter and the scale factor are
\[ H(t) \sim H_0 = \frac{\sqrt{2\pi} \xi}{8m_p^2}, \quad a(t) \sim e^{H_0 t} \quad \text{for large} \ t \quad (3.25) \]

The state parameter has the following explicit form
\[ w(t) = -1 - \frac{256\xi t^2 e^{2t^2\xi} m_p^2}{3 \left( -4t \sqrt{\xi} + e^{t^2\xi} \sqrt{2\pi} \text{erf}(\sqrt{2t\xi}) \right)^2} \quad (3.26) \]

The shapes of the potential, the Hubble parameter and the state parameter are presented at (Fig.8). It is interesting to note that the next to leading term in the asymptotic of (3.26) at large \( t \)
\[ w(t) \sim -1 - \frac{128 m_p^2 t^2 \xi e^{-2t^2\xi}}{3\pi} \quad (3.27) \]

is proportional to \( m_p^2 \) meanwhile from the general formula (1.7) one can expect that the deviation from the limiting value -1 could be proportional to \( 1/m_p^2 \). This is caused by a presence of a dependence of \( m_p^2 \) in \( H_0 \sim 1/m_p^2 \) and independence of \( \dot{\phi} \) on \( m_p^2 \).
4. Hyperbolic Lump

4.1 Numerical construction of the potential

Here we will be interested in the scalar SFT-type nonlocal models described by the following action

\[ S = \int d^4x \left[ \frac{1}{2} \dot{\phi}^2 - U(\Phi) \right], \]  

(4.1)

where \( U \) is a polynomial and \( \Phi \) the smoothed field given by (2.8). Action (4.1) leads to the equation of motion which on the space homogeneous configurations reads

\[ e^{\beta \partial^2_t} \Phi = U(\Phi) \]  

(4.2)

We assume that \( U \) has a form

\[ U(\Phi) = U(\bar{\alpha}) \equiv \sum_{n=1}^{N} \frac{\alpha_n}{n+1} \Phi^{n+1}, \]  

(4.3)

We choose a function

\[ \Phi_0(t) = \text{sech}^2(t) \]  

(4.4)

and find the set of coefficients \( \{\alpha_n\} \) from a requirement that that a discrepancy

\[ \delta_N(\bar{\alpha}) = e^{\beta \partial^2_t} \Phi - U'(\Phi) \]  

(4.5)

is small in \( L_2 \)-norm for fixed \( N \), where \( N \) is a number of terms in the series (4.3). For numerical calculations we use a representation of the left hand side of (4.2) in term of the integral operator

\[ e^{\beta \partial^2_t} \Phi(t) \equiv K(\Phi)(t) = \frac{1}{\sqrt{4\pi\beta}} \int_{-\infty}^{\infty} e^{-\frac{(t-\tau)^2}{4\beta}} \Phi(\tau) d\tau, \]  

(4.6)

and take \( \beta = \frac{1}{4} \). We denote the R.H.S. of (4.2) as a force \( F \)

\[ F_{\bar{\alpha}}[\Phi] \equiv F_{\alpha_N}[\Phi] = \sum_{n=1}^{N} \alpha_n \Phi^n, \]  

(4.7)

Note that numerical calculations show that we cannot make the discrepancy equal to zero for final \( N \), this illustrate the fig.9a).

\[ \begin{align*} 
\text{a)} & \quad \text{Minimum of the absolute value of the function of discrepancy } \delta_N(\bar{\alpha}) \text{ (in the logarithmic scale at pintle) depending on number of terms } N \text{ is presented; } \\
\text{b)} & \quad \Phi_0(t) = \text{sech}^2(t) \text{ is presented by dash line, function } K(\Phi_0)(t) \text{ is presented by the firm line and } \\
\text{c)} & \quad \text{a comparison of the function } K(\Phi_0)(t) \text{ with } e^{\beta \partial^2_t} \Phi_0(t) \text{ and } U'(\Phi_0) \text{ is presented.} 
\end{align*} \]
function $F_{\alpha_5}[^0\varphi]$ is presented by dotdashing line $N = 5$, coefficients $\alpha_5$ are collected on the Table; c) function $\delta_5(\alpha_5) = K[^0\varphi] - F_{\alpha_5}[^0\varphi]$.

Note that already for $N = 5$ the discrepancy is rather small, this illustrate the fig.9 b). The coefficients $\alpha$ for different $N$ are presented in the Table

| $N$ | $\alpha_1$  | $\alpha_2$  | $\alpha_3$  | $\alpha_4$  | $\alpha_5$  | $\alpha_6$  | $\alpha_7$  |
|-----|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| 3   | 1.896       | -2.2206     | 1.0649      | -           | -           | -           | -           |
| 5   | 2.319       | -5.7831     | 10.1891     | -9.1559     | 3.1602      | -           | -           |
| 6   | 2.4309      | -7.5998     | 19.2683     | -28.4428    | 21.4779     | -6.4098     | -           |
| 12  | 2.4628      | -8.2965     | 23.6528     | -38.931     | 28.6269     | 0.287057    | -6.3996     |
| 13  | 2.4643      | -8.3152     | 23.7106     | -38.965     | 28.5816     | 0.278636    | -6.3756     |
| 14  | 2.4662      | -8.3356     | 23.7655     | -38.985     | 28.5391     | 0.256198    | -6.3702     |
| 15  | 2.4602      | -8.2969     | 23.7264     | -39.024     | 28.5326     | 0.282346    | -6.3252     |

It is interesting to note that as follows from the fig. 9, there is a tendency of decreasing of the minimum value of the discrepancy when the number of terms in the series (4.3) is increase, moreover the values of the low-order coefficients are stabilized when $N$ is increase.

4.2 Numerical solution of the integral equation

We are going to solve the equation

$$K[y](t) = F_{\alpha_N}[y](t),$$

(4.8)

where the right hand side is given by $F_{\alpha_N}$, that minimized the discrepancy for the function (4.4) A solution of this equation we find using the following iteration procedure

$$y_{n+1} = y_n + \lambda(K[y] - F_{\alpha_N}[y]), \quad \lambda = 0.01,$$

(4.9)

and as the zero approximation we take (4.4), i.e. $y_0 = \text{sech}^2(t)$

Fig. 10: a) Zero iteration $y_0 = \text{sech}^2(t)$ is depicted by firm line and five hundredth 500 by dashing line($N = 5$); b) The discrepancy for initial iteration (the line with amplitude 0.003) and for solution $y(t)$ of equation (4.8)(the line with amplitude 0.001); c) The dependence for descrepancy (4.10) as function on number of iteration when the number of terms in the series $N = 5$.

Numerical calculations show that this iteration procedure converges. A character of a convergent of the iteration procedure is natural to specify by the a maximum of the discrepancy

$$\Delta[y_n] = \max_t |K[y_n](t) - F_{\alpha_N}[y_n](t)|$$

(4.10)
As we see that $\Delta[y_n]$ becomes smaller for a large number of iteration $n$ (when the number of terms in the series $N = 5$), however as we can see from Fig. (11) c) at $n \sim 500$ $\Delta[y_n]$ goes to a “plateau” and after decreases slowly. The same situation takes place when we consider the case when the number of terms in the series $N = 7, 14, 21, \ldots$ etc.

4.3 Mechanical problem

The mechanical problem that corresponds to (4.8) has the form

$$\beta \ddot{\varphi}(t) = F_\alpha[\varphi] - \varphi.$$  \hspace{1cm} (4.11)

The potential for this problem is $V_{\alpha}(\varphi)$

$$V_{\alpha}(\varphi) = \frac{1}{2} \varphi^2 - U_\alpha(\varphi).$$ \hspace{1cm} (4.12)

$V_{\alpha}(\varphi)$ is the overturn version of the potential $V$ given by (1.6) with $U$ given by (4.3).

Fig. 11: The overturn potential (4.12) when $N$ is equal: a) $N = 5$ and b) $N = 14$; c) the overturn potential $-V_0$

The overturn potentials for $N=5$ and $N=14$ are presented on fig. 11. It is interesting to note that global forms of corresponding potentials are different for different $N$ see fig. 11, but in all considered cases there are local maximum of the potential in the zero field configuration and points of local minimum.

Starting from the zero-energy bounce point, $\varphi(0) = \varphi_0$, where $V(\varphi_0) = 0$, with zero velocity, $\dot{\varphi}(0) = 0$, the particle moves to the local maximum of the potential at the point $\varphi = 0$ during infinite time. For the initial data $\varphi(0) = \varphi_1 < \varphi_0$ and $\dot{\varphi}(0) = 0$ the particle performs a periodic motion. For $\varphi(0) = \varphi_0$ and $\dot{\varphi}(0) \neq 0$ the motion is unbounded.

On Fig. 11 c) for a comparison we present the potential $-V_0$. As it is known (see also the subsection (4.5)) the lump (4.4) is a zero-energy solution of the mechanical problem with the phantom kinetic term and potential $V_0$ given by (1.18).

4.4 Energy and pressure

In this subsection similar to the subsection 2.3 we consider the energy and the pressure of the nonlocal problem (4.8) and compare them with energy and pressure of the corresponding mechanical problem (4.11). Equation (4.8) has the conserved energy functional

$$E = E_p + E_{nl1} + E_{nl2},$$  \hspace{1cm} (4.13)

where

$$E_p = -\frac{1}{2} \varphi^2 + U(\Phi),$$ \hspace{1cm} (4.14)
\[ E_{n1} = \frac{\beta}{2} \int_0^1 (e^{-\frac{4\rho}{2}\beta^2} U'(\Phi))(e^{\frac{4\rho}{2}\beta^2} \partial^2 \Phi) d\rho \]  

(4.15)

and

\[ E_{n2} = -\frac{a}{2} \int_0^1 ((e^{-\frac{4\rho}{2}\beta^2} U'(\Phi))(e^{\frac{4\rho}{2}\beta^2} \partial \Phi) d\rho. \]  

(4.16)

The pressure

\[ P = E_{n2} - E_p - E_{n1} \]  

(4.17)

has the representation $E_{n2}$ and

\[ P = -a \int_0^1 (e^{(2-\rho)\frac{4}{2}\beta^2} \partial \Phi)(e^{\frac{4\rho}{2}\beta^2} \partial \Phi) d\rho \]  

(4.18)

Fig. 12: a) The lump (4.4) and the corresponding smothered function (lowest positive line in the picture) and the pressure (4.18) for $N = 14$ (negative line).

**4.5 Exact Lump Solution in Friedmann Metric**

In the full analogy with what has been done in sect.3.3 we can easily find a potential for which the function (4.4) is a solution to the Friedmann equations. It has the form

\[ V(\phi) = 2 (1 - \phi)^2 - \frac{4 (-1 + \phi)^3 (2 + 3 \phi)^2}{75 m_p^2} \]  

(4.19)

The shape of the potential is presented at fig.13.a.

Fig. 13: a) The overturn potential $-V$, b) $H = H(t)$ as function on $t$; c) $w = w(t)$ as function on $t$

The Hubble parameter has the form

\[ H(t) = \frac{2 (4 + \cosh(2t)) \text{sech}(t)^2 \tanh(t)^3}{15 m_p^2} \]  

(4.20)
and its shape is presented on (Fig. 13 b). $H(t)$ and the scale factor $a(t)$ have the following asymptotic behavior at large $t$

$$H(t) \sim \frac{2}{15m_p^2}, \quad a(t) \sim e^{\frac{4}{15m_p^2}} \quad \text{for} \quad t \to \infty$$

(4.21)

The state parameter is given by the following explicit formula

$$w(t) = -1 - \frac{75 m_p^2 \coth(t)^4}{(4 + \cosh(2t))^2}$$

(4.22)

and we see that for large times $w(t)$ goes to $-1$.
